From an analysis of the oil by De Jongh, it appears to consist of a peculiar substance named gaduin; oleic and margaric acids with glycerin; butyric and acetic acids; various biliary principles, as fellinic, cholic, and bilifellinic acids, and bilifulvin; a peculiar substance soluble in alcohol; a peculiar substance insoluble in water, alcohol, or ether; iodine, chlorine, and traces of bromine; phosphoric and sulphuric acids, phosphorus, lime, magnesia, soda, and iron. These were found in all the varieties, though not in equal proportion in all; yet it is quite uncertain whether the difference had any relation to their degree of efficacy. *Gaduin* is obtained by saponifying the oil with soda, decomposing the soap by acetate of lead, and treating the resulting lead soap with ether, which dissolves the oleate of lead and gaduin, leaving the margarate of lead behind. The ethereal solution, which is dark-brown, is decomposed by sulphuric acid, which liberates the brown oleic acid. This owes its colour to gaduin, to separate which soda is added in excess; the resulting oleate of soda, which is insoluble in an excess of the alkali, is dissolved in alcohol; and the alcoholic solution is cooled below 32°, by which means the oleate of soda is separated, the gaduin remaining in solution. This is precipitated from its solution by the addition of sulphuric acid. Gaduin is a dark-brown substance, brittle and pulverizable when dry, without odour or taste, quite insoluble in water, and in great measure soluble in ether and alcohol. It is insoluble in nitric and muriatic acids, but is dissolved by sulphuric acid, giving a blood-red colour to the solution, from which it is precipitated by water and the alkalies. It is soluble in alkaline solutions. Chlorine decolorizes it. Its formula is $C_{35}H_{23}O_9$. Gaduin itself is yellow, but becomes brown by exposure to the air. It has not been ascertained to be in any degree connected with the virtues of the oil. It is not improbable that the biliary principles associated with the oil are concerned in its peculiar influences; as it is by their presence mainly that this differs from other oils. It has been thought that gaduin itself is of biliary origin. Winckler has inferred from his researches that cod-liver oil is an organic whole, differing from all other fixed oils. Thus, it yields no glycerin upon saponification, but, in place of it a peculiar body which he denominates oxide of propyle. The fatty acids generated are the oleic and margaric. By reaction with ammonia in distillation, the oil yields a peculiar volatile alkali, called *propylamin*, which has a strong pungent odour, recalling that of herring-pickle, of which the same alkali is an ingredient. No other officinal fatty oil yields a similar product. (See *Am. Journ. of Pharm.*, xxiv. 343.) Some have been disposed to ascribe the virtues of the oil to its iodine and bromine; but these are in too small proportion for much effect, and the oil has produced results which have never been obtained from iodine and bromine themselves. The presence of iodine cannot be detected by the usual tests. It is necessary to convert the oil into a soap, and to carbonize this before it will give evidence of iodine. The proportion never exceeds 0·05 per cent. or 1 part in 2000. The oil is capable of dissolving a larger proportion; and, if any specimen contain more, there is reason to suppose that it has been fraudulently added.

Tests of Purity. In consequence of the great demand for this oil it has not unfrequently been adulterated with other fixed oils, and occasionally others have been fraudulently substituted for it. The importance, therefore, is obvious of ascertaining some mode of testing its purity and genuineness. There is reason to believe that all the oils from the livers of the Gadidæ have analogous properties. They have been indiscriminately used; and upon the results of their employment is based, in part, the present reputation of the medicine. They may, therefore, be considered as in fact one oil, so far as their medicinal use is concerned. Unfortunately chemistry has yet discovered no perfectly reliable test. The

furthest that it has yet gone is to point out certain reactions which may be considered as evidences of the presence of biliary principles in the oil, thus indicating its hepatic origin. Among these probably the most characteristic is that of sulphuric acid, a drop of which, added to fresh cod-liver oil, causes a fine violet colour, soon passing into yellowish or brownish-red. Sometimes, instead of assuming the violet hue, the colour immediately becomes a clear red, or dark brownish-red. This is said to be especially the case with those specimens of the oil which have been prepared by boiling the livers with water. Strong nitric acid produces instantly, when agitated with the oil, a pinkish colour, which soon becomes brown. According to Winckler, the oil should afford the smell of herring-pickle when heated with potassa, lime, and muriate of ammonia. But the most reliable tests are the sensible properties of odour and taste. If there be none of the peculiar shoe-leather smell and taste, or if a strong lamp-oil odour is perceptible, the oil may be suspected. Little of importance can be inferred from the colour. Some have been disposed to prefer the dark offensive oil; but our own experience accords with that of those who have found the pale or light-brown equally efficient; and for facility of administration and acceptability to the stomach the latter is greatly preferable.

It is important that the oil should be secluded from the air, which effects a gradual change, no doubt impairing its efficiency. Hence, the vessels containing it should be full; and apothecaries ought to keep it in bottles well stopped, holding about the quantity generally wanted for use at one time.

Medical Properties and Uses. Cod-liver oil has been long popularly employed in Northern Europe in rheumatic and strumous diseases. It was first brought to the notice of the profession generally by German practitioners, and had acquired great reputation on the continent before it was used to any extent in Great Britain. At Manchester, in England, it was employed by the medical profession in the treatment of chronic rheumatism and gout, as early as 1766. But it was not until the appearance of the treatise of Professor Bennet, of Edinburgh, in 1841, that it came into general notice in Great Britain and the United States. It is at present one of the most esteemed remedies in the catalogue of the Materia Medica. The diseases in which it has proved most efficient are chronic rheumatism and gout, and the various morbid affections connected with a scrofulous diathesis, such as external glandular scrofula, diseases of the joints and spine, carious ulcers, tabes mesenterica, rickets, and phthisis. It has been found useful also in chronic cutaneous eruptions, lupus, ulcers of the mouth, some varieties of palsy, chronic pectoral complaints not tuberculous, obstinate constipation, intestinal worms, and incontinence of urine; and may be employed with the hope of good in all chronic cases in which the disease appears to consist mainly in impaired digestion, assimilation, and nutrition. In another publication, one of the authors has stated that he had employed the oil occasionally in phthisis, but with no other observable effect than to nauseate the stomach. This unfavourable experience was owing to a too hasty abandonment of the medicine, after a trial in each case of only two or three weeks. His opinion of its virtues has since changed; and he is now prepared to say that it has far exceeded in efficacy, in his hands, any other remedy or combination of remedies that he has hitherto employed in phthisis. It is necessary, however, to persevere for four or six weeks before looking for any decidedly favourable result, though the change does often begin earlier. In most cases remarkable temporary relief is afforded; in many, the disease is favourably modified, and its fatal termination postponed; and in some, cures appear to have been effected. Time, however, is yet wanted fully to determine its merits.

As to its mode of action, there has been much difference of opinion. Some consider it merely as a nutritive agent, having the advantage over other oleagi-

nous substances of a readier entrance into the system, and more easy assimilation. But we cannot agree with this opinion. Other oleaginous substances, certainly not less nutritious, have not been equally efficient, though taken in much larger quantities. If this be the true explanation, persons living chiefly on milk which abounds in oil, or on fat pork, ought to show a special exemption from scrofulous complaints. The probability appears to us to be that, in consequence of some peculiar principle or principles it contains, it exercises a stimulant and alterative impression on the processes of assimilation and nutrition; thereby causing the production of healthy tissue, instead of that abortive material which is deposited by the blood-vessels in scrofula and phthisis. With our views of the modus operandi of cod-liver oil, it would of course be contra-indicated in all cases where there is existing plethora, or a strong tendency to it. The medicine has been accused of having occasionally produced serious congestion of the lungs.

The dose is a tablespoonful three or four times a day for adults, a teaspoonful repeated as frequently for children, which may be gradually increased as the stomach will permit, and continued for a long time. It may be taken alone, or mixed with some vehicle calculated to conceal its taste, and obviate nauseating effects. For this purpose recourse may be had to any of the aromatic waters, to the aromatic tinctures, as the tincture of orange peel, diluted with water, or to a bitter infusion, as that of quassia. It may be given floating on the vehicle, or mixed with it by means of gum and sugar, in the form of an emulsion. Perhaps the best vehicle, when not contra-indicated, is the froth of porter. Let a tablespoonful of porter be put into the bottom of a glass, upon the surface of this the oil, and over all some of the froth of the porter. It is recommended to chew a small piece of orange-peel before and after taking the medicine. The oil is sometimes applied externally by friction, and, in cases of ascarides or lumbricoides, is injected into the rectum. It has been recommended locally in chronic articular affections, paralysis, various chronic cutaneous eruptions, and opacity of the cornea, after the subsidence of inflammation. In the last-mentioned affection, one or two drops of the oil are applied by means of a pencil to the cornea, and diluted, if found too stimulating, with olive or almond oil. It is said, when long used internally, to occasion sometimes an exanthematous or eczematous eruption. W.

OLEUM MYRISTICÆ. *U. S., Dub.*

Oil of Nutmeg.

The volatile oil of the kernels of the fruit of Myristica moschata. *U. S.* From the seeds or fruit. *Dub.*

Off. Syn. MYRISTICÆ OLEUM. Volatile oil from the kernels of the fruit of Myristica officinalis. *Ed.*

See MYRISTICA.

This oil is obtained from powdered nutmegs by distillation with water. It is colourless or of a pale straw colour, limpid, lighter than water, soluble in alcohol and ether, with a pungent spicy taste, and a strong smell of nutmeg. It consists of two oils, which may be separated by agitation with water, one rising to the surface, the other sinking to the bottom. Upon standing it deposits a crystalline stearoptene, which is called by John *myristicin*. The oil may be used for the same purposes as nutmeg, in the dose of two or three drops; but is not often employed.

OLEA. *Sex. Syst.* Diandria Monogynia.—*Nat. Ord.* Oleaceæ.

Gen. Ch. Corolla four-cleft, with subovate segments. *Drupe* one-seeded. *Willd.*

Olea Europœa. Willd. *Sp. Plant.* i. 44; Woodv. *Med. Bot.* p. 280, t. 98. This valuable tree is usually from fifteen to twenty feet in height, though it sometimes attains a much greater size, particularly in Greece and the Levant. It has a solid, erect, unequal stem, with numerous straight branches, covered with a grayish bark. The leaves, which stand opposite to each other on short footstalks, are evergreen, firm, lanceolate, entire, two or three inches in length, with the edges somewhat reverted, smooth and of a dull-green colour on their upper surface, whitish and almost silvery beneath. The flowers are small, whitish, and disposed in opposite axillary clusters, which are about half as long as the leaves, and accompanied with small, obtuse, hoary bractes. The fruit or olive is a smooth, oval drupe, of a greenish, whitish, or violet colour, with a fleshy pericarp, and a very hard nut of a similar shape. Clusters of flowers containing not less than thirty yield only two or three ripe olives.

The olive tree, though believed by some to have been originally from the Levant, flourishes at present in all the countries bordering on the Mediterranean, and has been cultivated from time immemorial in Spain, the South of France, and Italy. It begins to bear fruit after the second year, is in full bearing at six years, and continues to flourish for a century. There are several varieties, distinguished by the form of the leaves, and the shape, colour, and size of the fruit. The variety *longifolia* of Willdenow is said to be chiefly cultivated in Italy and the South of France, and the *latifolia* in Spain. The latter bears much larger fruit than the former; but the oil is less esteemed.

The leaves and bark of the olive tree have an acrid and bitterish taste, and have been employed as substitutes for cinchona, though with no great success. In hot countries, a substance resembling the gum-resins exudes spontaneously from the bark. It was thought by the ancients to possess useful medicinal properties, but is not now employed. Analyzed by Pelletier, it was found to contain resin, a little benzoic acid, and a peculiar principle analogous to gum, which has received the name of *olivile*. But the fruit is by far the most useful product of the tree. In the unripe state it is hard and insupportably acrid; but, when macerated in water or an alkaline solution, and afterwards introduced into a solution of common salt, it loses these properties, and becomes a pleasant and highly esteemed article of diet. The pericarp, or fleshy part of the ripe olive, abounds in a fixed oil, which constitutes its greatest value, and for which the tree is chiefly cultivated in the South of Europe. The oil is obtained by first bruising the olives in a mill, and then submitting them to pressure. The product varies much, according to the state of the fruit, and the circumstances of the process. The best oil, called *virgin oil*, is obtained from the fruit picked before perfect maturity, and immediately pressed. It is distinguished by its greenish hue. The common oil used for culinary purposes, and in the manufacture of the finest soaps, is procured from very ripe olives, or from the pulp

of those which have yielded the virgin oil. In the latter case, the pulp is thrown into boiling water, and the oil removed as it rises. An inferior kind, employed in the arts, especially in the preparation of the coarser soaps, plasters, unguents, &c., is afforded by fruit which has been thrown into heaps, and allowed to ferment for several days, or by the *marc* left after the expression of the finer kinds of oil, broken up, exposed to the fermenting process, and again introduced into the press.

Olive oil is imported in glass bottles, or in flasks surrounded by a kind of network made of grass, and usually called Florence flasks. The best comes from the South of France, where most care is exercised in the selection of the fruit.

Properties. The pure oil is an unctuous liquid, of a pale-yellow or greenish-yellow colour, with scarcely any smell, and a bland, slightly sweetish taste. Its sp. gr. is 0·9153. It is soluble in twice its volume of ether, but is only partially soluble in alcohol, at least unless this liquid be in very large proportion. It begins to congeal at 38° F. At a freezing temperature a part of it becomes solid, and the remainder, retaining the liquid consistence, may be separated by pressure, or by the agency of cold alcohol, which dissolves it. The concrete portion has been found by MM. Pelouze and Boudet to be a definite compound of margarin and olein; the liquid portion is uncombined olein. According to Braconnot, the oil contains 72 per cent of olein, and 28 of margarin. Olive oil is solidified by nitrous acid and by nitrate of mercury, and converted into a peculiar fatty substance, which has received the name of *elaïdin*. The olein of all oils which have not the drying property undergoes the same change, when acted on by nitrous acid; and the singular fact is stated by MM. Pelouze and Boudet, that the margarin of olive oil, combined as it is with olein, is converted by that acid into elaïdin, while the same principle, in a state of purity, is not affected by it. (*Journ. de Pharm.*, xxiv. 391.)

Olive oil, when exposed to the air, is apt to become rancid, acquiring a disagreeable smell, a sharp taste, a thicker consistence, and a deeper colour; and the change is promoted by heat. It is frequently adulterated with the cheaper fixed oils, especially with that of poppies; but the adulteration may be easily detected by reducing the temperature to the freezing point. As other oils are less readily congealed than the olive oil, the degree of its purity will be indicated by the degree of concretion. Another mode has been indicated by M. Poutet, founded on the property possessed by the supernitrate of mercury of solidifying the oil of olives, without a similar influence upon other oils. Six parts of mercury are dissolved at a low temperature in seven and a half parts of nitric acid of the sp. gr. 1·35; and this solution is mixed with the suspected oil in the proportion of one part to twelve, the mixture being occasionally shaken. If the oil is pure, it is converted after some hours into a yellow solid mass; if it contains a minute proportion, even so small as a twentieth of poppy oil, the resulting mass is much less firm; and a tenth prevents a greater degree of consistence than oils usually acquire when they concrete by cold. M. Gobel has invented an instrument which he calls the elaïometer, by which the smallest quantity of poppy oil can be detected. (See *Am. Journ. of Pharm.*, xvi. 24.) M. Diesel states that pure olive oil is coloured green by common nitric acid; whereas, if mixed with rape oil, it is rendered of a yellowish-gray colour. (*Arch. der Pharm.*, xlvi. 287.) According to M. Behrens, whose statement is confirmed by MM. Guibourt and Reveil, the presence of oil of sesamum is known by the beautiful deep-green colour immediately produced, when the suspected oil is added, in equal weight, to a mixture composed of equal parts of sulphuric and nitric acids; which acids cause with the pure oil, at first, a bright-yellow colour. (*Journ. de Pharm.*, 3e *sér.*, xxiv. 351.) Immense quantities of lard oil are said to be exported from this country to France, and employed in the adulteration of olive

oil. The reaction with nitric acid would probaby serve to detect this adulteration, which, however, in a pharmaceutical point of view, is of little inconvenience.

Medical Properties and Uses. Olive oil is nutritious and mildly laxative, and is occasionally given in cases of irritable intestines, when the patient objects to more disagreeable medicines. Taken into the stomach in large quantities, it serves to involve acrid and poisonous substances, and mitigate their action. It has also been recommended as a remedy for worms, and is a very common ingredient in laxative enemata. Externally applied, it is useful in relaxing the skin, and sheathing irritated surfaces from the action of the air; and is much employed as a vehicle or diluent of more active substances. In the countries bordering on the Mediterranean, it is thought, when smeared over the skin, to afford some protection against the plague; and applied warm, by means of friction over the surface, is said to be useful as a remedy in the early stages of that complaint. But the most extensive use of olive oil is in pharmacy, as a constituent of liniments, ointments, cerates, and plasters.

The dose as a laxative is from one to two fluidounces.

OLEUM RICINI. *U. S., Dub.*

Castor Oil.

The oil of the seeds of Ricinus communis. *U. S., Dub.*

Off. Syn. RICINI OLEUM. Ricinus communis. Oil obtained from the seeds by heat or pressure. *Lond.* Expressed oil of the seeds. *Ed.*

Huile de ricin, *Fr.;* Ricinusöl, *Germ.;* Olio di ricino, *Ital.;* Aceyte de ricino, *Span.*

RICINUS. *Sex. Syst.* Monœcia Monadelphia.—*Nat. Ord.* Euphorbiaceæ.

Gen. Ch. MALE. *Calyx* five-parted. *Corolla* none. *Stamens* numerous. FEMALE. *Calyx* three-parted. *Corolla* none. *Styles* three, bifid. *Capsules* three-celled. *Seed* one. *Willd.*

Ricinus communis. Willd. *Sp. Plant.* iv. 564; Woodv. *Med. Bot.* p. 624, t. 221. The castor oil plant, or *palma Christi*, attains in the East Indies and Africa the character of a tree, and rises sometimes thirty or forty feet in height. In the temperate latitudes of North America and Europe it is an annual plant; though it is stated by M. Achille Richard that, in the South of France, in the vicinity of Nice, on the seacoast, he saw a small wood consisting entirely of this species of Ricinus. The following description applies to the plant as cultivated in cool latitudes. The stem is of vigorous growth, erect, round, hollow, smooth, glaucous, somewhat purplish towards the top, branching, and from three to eight feet or more in height. The leaves are alternate, peltate or supported upon footstalks inserted into their lower disk, palmate with seven or nine pointed serrate lobes, smooth on both sides, and of a bluish-green colour. The flowers are monœcious, stand upon jointed peduncles, and form a pyramidal terminal raceme, of which the lower portion is occupied by the male flowers, the upper by the female. Both are destitute of corolla. In the male flowers the calyx is divided into five oval, concave, pointed, reflected, purplish segments; and encloses numerous stamens, which are united into fasciculi at their base. In the female the calyx has three or five narrow lanceolate segments; and the ovary, which is roundish and three-sided, supports three linear, reddish stigmas, forked at their apex. The fruit is a roundish glaucous capsule, with three projecting sides, covered with tough spines, and divided into three cells, each containing one seed, which is expelled by the bursting of the capsule.

This species of Ricinus is a native of the East Indies and Northern Africa, has become naturalized in the West Indies, and is cultivated in various parts of

the world, in no country perhaps more largely than in the United States. New Jersey, Virginia, North Carolina, and the States upon the right bank of the Ohio, are the sections in which it is most abundant. The flowers appear in July, and the seeds ripen successively in August and September. A decoction of the leaves is said to be employed effectively, in the Cape Verde Islands, as a local application to the breast, for the purpose of promoting lactation. The officinal part is the fixed oil extracted from the seeds.

1. The Seeds. These are about as large as a small bean, oval, compressed, obtuse at the extremities, very smooth and shining, and of a grayish or ash colour, marbled with reddish-brown spots and veins. At one end of the seed is a small yellowish tubercle, from which an obscure longitudinal ridge proceeds to the opposite extremity, dividing the side upon which it is situated into two flattish surfaces. In its general appearance the seed is thought to resemble the insect called the *tick*, the Latin name of which has been adopted as the generic title of the plant. Its variegated colour depends upon a very thin pellicle, closely investing a hard, brittle, blackish, tasteless, easily separable shell, within which is the kernel, highly oleaginous, of a white colour, and a sweetish taste succeeded by a slight degree of acrimony. The seeds easily become rancid, and are then unfit for the extraction of the oil, which is acrid and irritating. In 100 parts of the seeds Geiger found, exclusive of moisture, 23·82 parts of envelope, and 69·09 of kernel. These 69·09 parts contained 46·19 of fixed oil, 2·40 of gum, 20·00 of starch and lignin, and 0·50 of albumen.

Taken internally the seeds are powerfully cathartic, and often emetic. Two or three are sufficient to purge, and seven or eight act with great violence. This property depends upon an acrid principle, which has by some been thought to exist exclusively in the integuments, by others in the embryo. But it is now satisfactorily ascertained that the integuments are inert; and Guibourt maintains that the principle alluded to pervades the whole kernel, in connexion with the oil. This principle is considered by some as volatile, and is said to be dissipated by the heat of boiling water. According to MM. Soubeiran and Mialhe, it is of a resinous character. (*Journ. de Pharm.*, 3*e sér.*, vi. 225.) M. Calloud, however, considers it neither oily nor resinous; having found the residue of the seeds, after expression of the oil, and treatment with pure alcohol, to be powerfully emetic in the quantity of thirty grains, taken in two doses. (*Ibid.*, xiv. 190.) M. Parola states that ether also is incapable of extracting the acrid emetic principle from the seeds. At a temperature much above 212° the oil itself becomes altered, and acquires acrid properties.

2. The Oil. This may be extracted from the seeds in three ways; 1. by decoction, 2. by expression, and 3. by the agency of alcohol.

The process by decoction, which has been practised in the East and West Indies, consists in bruising the seeds, previously deprived of their husk, and then boiling them in water. The oil, rising to the surface, is skimmed or strained off, and afterwards again boiled with a small quantity of water to dissipate the acrid principle. To increase the product it is said that the seeds are sometimes roasted. The oil is thus rendered brownish and acrid; and the same result takes place in the second boiling, if care is not taken to suspend the process soon after the water has been evaporated. Hence it happens that the West India oil has generally a brownish colour, an acrid taste, and irritating properties.

The oil is obtained, in this country, by expression. The following, as we have been informed, are the outlines of the process usually employed by those who prepare it on a large scale. The seeds, having been thoroughly cleansed from the dust and fragments of the capsules with which they are mixed, are conveyed into a shallow iron reservoir, where they are submitted to a gentle heat insufficient to scorch or decompose them, and not greater than can be readily borne by the

hand. The object of this step is to render the oil sufficiently liquid for easy expression. The seeds are then introduced into a powerful screw press. A whitish oily liquid is thus obtained, which is transferred to clean iron boilers, supplied with a considerable quantity of water. The mixture is boiled for some time, and, the impurities being skimmed off as they rise to the surface, a clear oil is at length left upon the top of the water, the mucilage and starch having been dissolved by this liquid, and the albumen coagulated by the heat. The latter ingredient forms a whitish layer between the oil and the water. The clear oil is now carefully removed; and the process is completed by boiling it with a minute proportion of water, and continuing the application of heat till aqueous vapour ceases to rise, and till a small portion of the liquid, taken out in a vial, preserves a perfect transparency when it cools. The effect of this last operation is to clarify the oil, and to render it less irritating by driving off the acrid volatile matter. But much care is requisite not to push the heat too far, as the oil then acquires a brownish hue, and an acrid peppery taste. After the completion of the process, the oil is put into barrels, and thus sent into the market. There is reason, however, to believe that much of the American oil is prepared by merely allowing it to stand for some time after expression, and then drawing off the supernatant liquid. One bushel of good seeds yields five or six quarts, or about twenty-five per cent. of the best oil. If not very carefully prepared, it is apt to deposit a sediment upon standing; and the apothecary often finds it necessary to filter it through coarse paper before dispensing it. Perhaps this may be owing to the plan just alluded to of purifying the oil by rest and decantation.* We have been told that the oil in barrels occasionally deposits a copious whitish sediment in cold weather, which it redissolves when the temperature rises. A large proportion of the drug consumed in the eastern section of the Union is derived, by way of New Orleans, from Illinois and the neighbouring States, where it is so abundant that it has sometimes been used for burning in lamps.

The process for obtaining castor oil by means of alcohol has been practised in France; but the product is said to become rancid more speedily than that procured in the ordinary mode. Such a preparation has been employed in Italy, and is asserted to be less disagreeable to the taste, and more effective than the common oil obtained by expression. According to M. Parola, an ethero-alcoholic extract, and an ethereal or alcoholic tincture of the seeds, operate in much smaller doses than the oil, and with less disposition to irritate the bowels or to cause vomiting. (See *Am. Journ. of Med. Sci.*, N. S., xiii. 143.)

Properties. Pure castor oil is a thick, viscid, colourless liquid, with little or no odour, and a mild though somewhat nauseous taste, followed by a slight sense of acrimony. As found in the shops it is often tinged with yellow, and has an unpleasant smell; and parcels are sometimes though rarely met with, of a brownish colour, and hot acrid taste. It does not readily congeal by cold. When exposed

* We find the following sentence in Christison's Dispensatory, p. 793. "If the statement made above on the authority of Boutron-Charlard, be correct [that no margarin is deposited by castor oil previously heated to 212°], this circumstance [the deposition of a crystalline matter by castor oil in cold weather], instead of being an objection, is strong proof of the American oil being really cold drawn, and not prepared by dry heat and ebullition as Drs. Wood and Bache have represented." In reply to this observation we have only to say, that we have ourselves witnessed the arrangements above described, and had the account of the steps of the process from the manufacturers, as it was at the time conducted in this city. But it may be observed that we do not state that the oil is prepared by dry heat; the warmth first employed, merely to render the oil fluid, not deserving to be so called. That American castor oil is also prepared by mere expression, rest, and decantation, we have stated in the text; but we are disposed to give the preference to that prepared by the former process, as freer from impurities, and therefore likely to keep better, and as milder in its action in consequence of the volatilization of a portion of the acrid principle.

to the air it slowly thickens, without becoming opaque, and it ranks among the drying oils. It is heavier than most of the other fixed oils, from which it differs also in being soluble in all proportions in cold absolute alcohol. Weaker alcohol, of the sp. gr. 0·8425, takes up about three-fifths of its weight. It has been supposed that adulterations with other fixed oils might thus be detected, as the latter are much less soluble in that fluid; but Pereira has shown that castor oil has the property of rendering a portion of other fixed oils soluble in alcohol; so that the test cannot be relied on. (*Pharm. Journ. and Trans.*, ix. 498.) Such adulterations, however, are seldom practised in this country. Castor oil is also soluble in sulphuric ether. Its proximate composition is but imperfectly understood. When distilled, it yields, according to MM. Bussy and Lecanu, 1. a colourless, highly odorous volatile oil, which crystallizes by cold, 2. two oleaginous acids, denominated ricinic and ricin-oleic, which are excessively acrid and nearly concrete, and 3. a solid spongy residue, amounting to two-thirds of the oil employed. Supposing these acids to be developed by heat, we can readily account for the injurious influence of too high a temperature in the preparation of the oil. By the action of nitrous acid, it is converted into a peculiar oleaginous substance called *palmin*, which yields *palmic acid* and glycerin when saponified. Alkalies unite with castor oil forming soaps, and determine the formation of three acids, the *ricinic*, *ricin-oleic*, and *ricino-stearic acids*, which can be obtained separate. Hence it has been inferred that the oil consists of three principles, for which the names of *ricin*, *ricinolein*, and *ricino-stearin* have been proposed. (*Kane's Chemistry.*) These principles, however, have not been isolated. M. Lefort gives the formula $C_{56}H_{52}O_8$ as representing the composition of castor oil. (*Journ. de Pharm.*, 3e *sér.*, xxiii. 348.) Its purgative property is supposed by MM. Bussy and Lecanu to belong essentially to the oil itself, and not to reside in any distinct principle which it may hold in solution.

Castor oil which is acrid to the taste may sometimes be rendered mild by boiling it with a small proportion of water. If turbid, it should be clarified by filtration through coarse paper. On exposure to the air, it is apt to become rancid, and is then unfit for use.

Medical Properties and Uses. Good castor oil is a mild cathartic, speedy in its action, usually operating with little griping or uneasiness, and evacuating the contents of the bowels without much increasing the alvine secretions. Hence, it is particularly applicable to cases of constipation from collections of indurated feces, and to those cases in which acrid substances have been swallowed, or acrid secretions have accumulated in the bowels. From its mildness it is also especially adapted to diseases attended with irritation or inflammation of the bowels, as colic, diarrhœa, dysentery, and enteritis. It is habitually resorted to in cases of pregnant and puerperal women; and is decidedly, as a general rule, the best and safest cathartic for children. Infants usually require a larger relative dose than adults, probably because they digest a larger proportion of the oil.

The dose for an adult is about a fluidounce, for an infant from one to three or four fluidrachms. It is sometimes of exceedingly difficult administration, not so much from any peculiarly disagreeable taste, as from the recollection of former nausea, or other uneasiness which it may have produced, and from its clamminess and unpleasant adhesiveness to the mouth. In a few cases, the disgust which it excites is utterly unconquerable by any effort of resolution. It is desirable, therefore, to obviate this inconvenience as far as possible by the mode of exhibition. A common method is to give it floating on the surface of mint or cinnamon water; but that which we have found upon the whole the least offensive, is to mix it with a cup of hot sweetened coffee, by which it is rendered more fluid, and its taste considerably disguised. Some take it in wine, or spirituous liquors, or the froth of porter; but these are often contra-indicated in the cases to which the medicine

is applicable. When the stomach is unusually delicate, the oil may be made into an emulsion with mucilage or the yolk of an egg, loaf sugar, and some aromatic water. Tragacanth has been recommended as producing a better emulsion than gum Arabic. Laudanum may be added to the mixture in cases of intestinal irritation. M. De Rudder proposes to give the oil in the air-bladders of fishes, which may be preserved in alcohol for the purpose. Castor oil may also be beneficially used as an enema, in the quantity of two or three fluidounces, mixed with some mucilaginous liquid. It has been recommended as a local application to the breasts of nursing women, to promote the secretion of milk.

Though apt to become rancid by itself, it loses much of this susceptibility when mixed with lard; and some apothecaries are said to use it as a substitute for olive oil in unguents and cerates. But the slightly irritating properties of even the mildest castor oil render it unfit for those preparations which are intended to alleviate irritation.

OLEUM ROSÆ. *U. S., Dub.*

Oil of Roses.

The volatile oil of the petals of Rosa centifolia. *U. S., Dub.*

Off. Syn. ROSÆ OLEUM. Volatile oil of the petals of Rosa centifolia. *Ed.* See ROSA CENTIFOLIA.

This is commonly called *attar*, *otto*, or *essence of roses*. It is prepared on a large scale in Egypt, Persia, Cashmere, India, and other countries of the East, by distilling the petals of the rose with water. The oil concretes and floats upon the surface of the water when it cools. The precise species of rose from which the oil is extracted is not in all instances certainly known; but it is said to be obtained from *R. damascena* in Northern India, *R. moschata* in Persia, and *R. centifolia* (*provincialis*) in the North of European Turkey. It is furnished in very minute proportion; not more than three drachms having been obtained by Colonel Polier, in Hindostan, from one hundred pounds of the petals. It is usually imported in small bottles, and is very costly.

Oil of roses is said to be prepared in Macedonia by crushing the petals in mills, expressing the fluid part, filtering it, and then exposing it to the sun in small glass vessels. The oil gradually collects on the surface of the liquid, and is removed. (*Pharm. Cent. Blatt*, 1847, p. 783.)

Landerer states that, at Damascus and other parts of Asia Minor, the oil is prepared by dry distillation. The buds being collected before sunrise are placed in a glass retort; and the distillation is effected by a salt-water bath, care being taken so to regulate the heat as not to scorch the petals. The water of the fresh roses and their oil come over together, and the latter, floating on the top, is separated in the usual mode. (See *Am. Journ. of Pharm.*, xxiii. 336.)

Oil of roses is nearly colourless, or presents some shade of green, yellow, or red; but, according to Polier, the colour is no criterion of its value. It is concrete below 80°, and becomes liquid between 84° and 86°. Its odour is very powerful and diffusive. At 90° its sp. gr. is 0·832. Alcohol dissolves it, though not freely when cold. It consists of two oils, one liquid, the other concrete at ordinary temperatures. These may be separated by freezing the oil, and compressing it between folds of blotting paper, which absorbs the liquid oil or eleoptene, and leaves the concrete or stearoptene. The latter consists exclusively of carbon and hydrogen; the former, of these and oxygen.

Sandal-wood oil, other volatile oils, fixed oils, spermaceti, &c., are said to be added as adulterations. The volatile additions may be detected by not being

concrete; the fixed, by the greasy stain they leave on paper when heated. Guibourt has offered certain tests by which he thinks the purity of the oil may be determined. The reader may find an account of them in the *American Journal of Pharmacy* (xxi. 318). It is said that the oil of one of the sweet-scented Pelargoniums, perhaps the *rose-geranium*, is much employed in Turkey for the purpose of adulteration, to which it is adapted by its odour, and by the circumstance that it concretes like the oil of roses. (*N. Y. Journ. of Pharm.*, i. 47.)

Oil of roses may be added, as a very grateful perfume, to various spirituous preparations for internal use, and to cerates and ointments.

Oil of Turpentine.

The volatile oil distilled from the turpentine of Pinus palustris and other species of Pinus. *U. S.* From the turpentine of Pinus sylvestris. *Dub.*

Off. Syn. TEREBINTHINÆ OLEUM. Pinus palustris, and P. Tœda? Oil distilled from the turpentine and rectified. *Lond.* Volatile oil of the liquid resinous exudation of various species of Pinus and Abies. *Ed.*

Huile volatile de térébenthine, *Fr.;* Terpenthinöl, *Germ.;* Olio della trementina, *Ital.;* Aceyte de trementina, *Span.*

See TEREBINTHINA.

This oil is commonly called *spirits* or *spirit of turpentine*. It is prepared by distillation from our common turpentine, though equally afforded by other varieties. It may be distilled either with or without water; but in the latter case a much higher temperature is required, and the product is liable to be empyreumatic. To obtain it absolutely pure it should be redistilled from a solution of caustic potassa. The turpentine of the *Pinus palustris* is said to yield about 17 per cent. of oil; while the common turpentine of Europe affords 24 per cent. Large quantities of the oil are distilled in North Carolina for exportation.

Pure oil of turpentine is perfectly limpid and colourless, of a strong, penetrating, peculiar odour, and a hot, pungent, bitterish taste. It is much lighter than water, having the sp. gr. 0·86 at 72° F.; is highly volatile and inflammable; boils at a temperature somewhat higher than 300°; is very slightly soluble in water, less soluble in alcohol than most other volatile oils, and readily soluble in sulphuric ether. Boiling alcohol dissolves it with facility, but deposits most of the oil upon cooling. One hundred parts of alcohol of 0·84 dissolve 13·5 parts of the oil at 72°. As found in commerce, it always contains oxygen; but, when perfectly pure, it consists exclusively of carbon and hydrogen, and is thought to be isomeric with the radical of camphor. Hence it has been denominated camphene. (See *page* 162.) According to Blanchet and Sell, it consists of two distinct isomeric oils, which, by the absorption of oxygen, are converted into two distinct resins, corresponding to those found by Unverdorben in colophony. (*Journ. de Pharm.*, xx. 226.) But there is reason to believe that these oils are the results of chemical reaction; as, when isolated, they have boiling points higher than that of the original oil. Heated in close vessels to 482° F., oil of

turpentine undergoes certain changes in properties, without any discoverable change of composition. (*Ibid.*, 3*e sér.*, xxiv. 428.) It absorbs muriatic acid, forming with it two compounds, one a red dense liquid, the other a white crystalline substance resembling camphor, and hence called *artificial camphor*. The latter consists of the unaltered oil (camphene) combined with the acid, and is therefore muriate of camphene. In the former the oil appears to have undergone some molecular change, being converted into an oil isomeric with the oil of turpentine, but differing from it in its action on polarized light, and in forming a liquid compound with muriatic acid. If the muriate of camphene be distilled with lime, the acid is retained, and an oil comes over, differing from pure oil of turpentine in having no action on polarized light, and from the oil just mentioned in forming a solid compound with muriatic acid. These three oils are said to be isomeric. (Soubeiran and Capitaine, *Journ. de Pharm.*, xxvi. 11.) Nitric acid converts oil of turpentine into resin, and by long boiling into *turpentinic acid*. Mixed with water and chloride of lime, and submitted to distillation, the oil yields a liquid which M. Chautard found to be identical with chloroform. (*Journ. de Pharm.*, 3*e sér.*, xxi. 88.) On exposure to the air and light, it deposits a white solid matter in acicular crystals, which are without taste or smell, insoluble in cold water, but soluble in ether and alcohol. (Boissenot, *Journ. de Chim. Méd.*, ii. 143.) White crystals of stearoptene, heavier than water and fusible at 20°, separate from the oil at the temperature of 18° below zero. These are probably a hydrate of the oil.

Exposed to the air the oil absorbs oxygen, becomes thicker and yellowish, and loses much of its activity, owing to the formation of resin. A small proportion of formic acid is said also to be generated. Hence the Edinburgh College directs a process for the rectification of the oil, consisting in distilling it with about four measures of water. But the process is difficult, in consequence of the great inflammability of the vapour, and its rapid formation, which causes the liquid to boil over. In this country it is scarcely necessary; as the recent oil can be obtained at an expense less than that which would be incurred by its redistillation on a small scale. Another mode of purifying the oil is to agitate it with one-eighth of alcohol, which dissolves the resinous portion. About one-fifth of the alcohol is retained by the oil, but is readily separated by agitation with water.

Medical Properties and Uses. Oil of turpentine is stimulant, diuretic, occasionally diaphoretic, anthelmintic, in large doses cathartic, and externally rubefacient. When swallowed in moderate quantities it produces a sense of warmth in the stomach, accelerates the circulation, and increases the heat of the skin, without especially affecting the functions of the brain. In small doses, frequently repeated, it stimulates the kidneys, augmenting the secretion of urine, and often producing, especially if long continued, painful irritation of the urinary passages, amounting sometimes to violent strangury. At the same time it imparts the odour of violets to the urine; and this effect is also produced by its external application, or even by breathing the air of an apartment impregnated with its vapours. In large doses it occasions slight vertigo, or a sense of fulness in the head, sometimes amounting to intoxication, attended frequently with nausea, and succeeded generally, though not always, by speedy and brisk catharsis. When this effect is experienced, the oil is carried out of the bowels, and, no time being allowed for absorption, is less apt to irritate the kidneys and bladder than when taken in small and repeated doses. In some constitutions it produces, even when taken internally, an erythematic eruption on the skin. Persons who inhale its vapour are liable to strangury and even bloody urine. The author has seen cases of hæmaturia in seamen from on board vessels loaded with turpentine.

The oil is employed in numerous diseases. As a stimulant it is useful in low

forms of fever, particularly in cases where there is reason to suspect ulceration of the mucous membranes. There is a particular state of fever usually attended with much danger, in which we have found this remedy almost uniformly successful. The condition of things alluded to, is one which occurs in the latter stages of typhoid fever, or lingering remittents, in which the tongue, having more or less completely thrown off its load of fur in patches, has suddenly become dry and brownish. The skin is at the same time dry, the bowels distended with flatus, and the patient sometimes affected with stupor or delirium. Under the use of small doses of oil of turpentine frequently repeated, the tongue becomes moist and again coated, the tympanitic state of the bowels disappears, and the patient goes on to recover as in a favourable case of fever. We have also found it extremely useful in the advanced stages of typhoid fever when the tongue is dry, independently of the special condition referred to; and are disposed to ascribe the effect to a healthy change produced by the oil in the ulcerated surface of the intestines. The medicine has been recommended as a counter-irritant in yellow and puerperal fevers; and may undoubtedly be given with advantage in the latter stages of these diseases, and in other instances of gastric and enteric inflammations, which require a resort to stimulation. In chronic rheumatism, particularly sciatica and lumbago, the oil has often been given with great benefit. It has also been much extolled as a remedy in neuralgia, in epilepsy and tetanus, in passive hemorrhages, particularly from the bowels, in disordered conditions of the alimentary canal attended with sallow countenance, foul tongue, tumid abdomen, sour or fetid eructations, and general depravation of health, in obstructions of the bowels, in chronic dysentery and diarrhœa, in obstinate gleets and leucorrhœa, in suppression of urine and retention and incontinence of urine from debility, and in chronic nephritic and calculous affections. In certain cases of dysentery whether acute or chronic, when the tongue is quite dry, and smooth as if from defect of the papillary structure, no remedy has proved so efficient in our hands as oil of turpentine. We have seen it also very beneficial in hæmoptysis. As a vermifuge it is highly esteemed, especially in cases of tænia. It appears, by its poisonous operation, to destroy or debilitate the worm, which, losing its hold upon the bowels, is then easily discharged. In cases of worms in the stomach it is often very useful. The worms, in this instance, are destroyed and digested as any other dead animal matter. In dropsies with feeble action the oil may sometimes be advantageously given as a diuretic; and in amenorrhœa from torpor of the uterine vessels it is occasionally useful. As a local stimulant or carminative it may be given beneficially in some instances of flatulent colic, and gout in the stomach.

The dose for ordinary purposes is from five to thirty drops, repeated every hour or two in acute, and three or four times a day in chronic diseases. In rheumatism it is recommended by some in the dose of a fluidrachm every four hours. As a remedy for the tape-worm it is given in the quantity of one or two fluidounces, and should be followed by castor oil if it do not operate in three or four hours. It has also proved successful in tænia in the dose of half a drachm, twice a day, continued for a considerable time. In ordinary cases of worms, the usual dose may be given. It may be administered on sugar, or in emulsion with gum Arabic, loaf sugar, and cinnamon or mint water.

In the form of enema, the oil has been employed in amenorrhœa, and to promote uterine contraction in child-birth, and is highly useful in cases of ascarides, obstinate constipation, and distension of the bowels from accumulation of air. No remedy is more effectual in tympanites than injections of the oil of turpentine. From half a fluidounce to two fluidounces may be administered in this way, suspended by the yolk of eggs in half a pint or a pint of water, or some mucilaginous fluid.

Externally applied, the oil of turpentine irritates and speedily inflames the skin; and, in low forms of fever with coldness of the surface, is when heated one of the most efficacious rubefacients. It is also used as a liniment in rheumatic and paralytic affections, and various internal inflammations. It should generally, in mild cases, be diluted with olive oil; and in some constitutions, even in this state, produces such violent inflammation of the skin, with extensive eruptions, as to render its external use in any shape improper. Mixed with some mild oil and introduced on cotton into the ear, it is sometimes beneficial in deafness arising from a deficient or unhealthy secretion of wax. Applied to recent burns, it is thought by some to be highly useful in allaying the burning pain, and promoting a disposition to heal. For this purpose, however, it is usually mixed with the resin cerate (*basilicon ointment*), so as to form a liniment capable of being spread upon linen rags. (See *Linimentum Terebinthinæ.*)*

Oil of turpentine has been recommended in the form of bath, in affections in which its constitutional impression is desired. For this purpose Dr. T. Smith, of Cheltenham, England, employs from five to ten fluidounces of the oil, with half a fluidounce of the oil of rosemary, and two pounds of carbonate of soda in each bath. The breath becomes strongly impregnated with the terebinthinate odour. (*Braithwaite's Retrospect*, xxi. 355.) Baths of the vapour of turpentine are stated to be very beneficial in chronic rheumatism. They are said to be borne well, for twenty-five minutes, at a temperature from 140° to 160° F. (*Arch. Gén.*, 4*e sér.*, xxviii. 80.)

Croton Oil.

The oil of the seeds of Croton Tiglium. *U. S.*

Off. Syn. TIGLII OLEUM. Croton Tiglium. Oil expressed from the seeds. *Lond.*; CROTONIS OLEUM. Expressed oil of the seeds of Croton Tiglium. *Ed.*; CROTON OIL. Croton Tiglium. The expressed oil of the seeds. *Dub.* Huile de Croton, *Fr.*; Crotonöl, *Germ.*; Nervalum unnay, *Tamool.*

CROTON. See Cascarilla.

Croton Tiglium. Willd. *Sp. Plant.* iv. 543; Woodv. *Med. Bot.* 3d ed., vol. 5, p. 71. This species of Croton is a small tree or shrub, with a few spreading branches, bearing alternate petiolate leaves, which are ovate, acuminate, serrate, smooth, of a dark-green colour on the upper surface, paler beneath, and furnished with two glands at the base. The flowers are in erect terminal racemes, scarcely as long as the leaf—the lower being female, the upper male, with straw-coloured petals. The fruit is a smooth capsule, about the size of a filbert, with three cells, each containing a single seed.

The tree is a native of Hindostan, Ceylon, the Moluccas, and other parts of continental and insular India. It is pervaded throughout by an acrid purgative principle, which is probably analogous to that found in other plants belonging to the family of Euphorbiaceæ. Rumphius says that the root is employed in Amboyna, in the dose of a few grains, as a drastic purge in dropsy; and, ac-

* The following is the formula adopted by the Philadelphia College of Pharmacy for the preparation of the rubefacient liniment, so much sold under the name of *British oil*. ℞. Olei Terebinth. f℥viij, Olei Lini f℥viij, Olei Succini f℥iv, Olei Juniperi f℥iv, Petrolei Barbadensis f℥iij, Petrolei Americani (Seneca oil) f℥j. Misce. (*Journ. of the Phil. Col. of Pharm.*, v. 29.)

cording to the same author, the leaves are so acrid that, when chewed and swallowed, they excite inflammation in the lips, mouth, throat, and along the whole course of the alimentary canal. The wood is said in small doses to be diaphoretic, in larger, purgative and emetic. But the seeds are the most active portion of the plant. These have been long employed in India as a powerful purgative, and were introduced so early as the year 1630 into Europe, where they were known by the names of *Grana Molucca* and *Grana Tiglia*. But in consequence of their violent effects they passed into neglect, and had ceased to be ranked among medicines, when, at a recent period, attention was again called to them by the writings of some English physicians in India. They are now imported for the sake of their oil, which is the only product of the plant considered officinal.

These seeds are rather larger than a grain of coffee, of an oblong form, rounded at the extremities, with two faces, the external considerably more convex than the internal, separated from each other by longitudinal ridges, and each divided by a similar longitudinal ridge, so that the whole seed presents an irregular quadrangular figure. Sometimes, as in the grain of coffee, their internal surface is flat with a longitudinal groove, owing to the presence of only two seeds in the capsule, the groove being produced by the central column or axis. The shell is covered with a soft yellowish-brown epidermis, beneath which the surface is black and smooth; and, as the epidermis is often partially removed by friction during their carriage, the seeds as they come to us are frequently of a mottled appearance, and sometimes nearly black. The kernel or nucleus is of a yellowish-brown colour, and abounds in oil. In India the seeds are prepared for use by submitting them to slight torrefaction, by which the shell is rendered more easily separable. In the dose of one or two grains the kernel purges with great activity.

The oil is obtained by expression from the seeds, previously deprived of the shell. It may also be separated by decoction in water, or by the action of ether, which dissolves the oil, and leaves it behind when evaporated. Guibourt recommends, after the first expression, to digest the residue with alcohol at a temperature of 120° to 140° F., and then submit it to a new expression. The alcohol is to be separated by distillation from the oil, which is then to be mixed with the first product. According to Dr. Nimmo, the seeds consist of 64 parts of kernel, and 36 of envelope in the hundred. From the seeds imported into England, about 22 per cent. of oil is obtained by simple expression. Guibourt, by his process, obtained 52 per cent. from the kernels, equivalent to about 35 per cent. of the seeds. Croton seeds yielded to Brandes upon analysis, independently of the shell, traces of a volatile oil, fixed oil, a peculiar fatty acid called *crotonic acid*, an alkaloid which he called *crotonin*, resin, stearin, wax, extractive, sugar, starch, gum, albumen, gluten, lignin, and salts. The crotonin has been subsequently found to be nothing more than a magnesian soap with an alkaline reaction. The *crotonic acid* is the most interesting ingredient, is thought to be the active principle of the seeds, and is separated along with the oil in expression. It may be obtained by treating the oil with solution of potassa, decomposing the resulting soap by tartaric acid, filtering and distilling the solution, neutralizing the product with baryta water, evaporating to dryness, decomposing the salt of baryta with strong phosphoric acid, and again distilling. (*Christison's Dispensatory.*) The acid solidifies at 23° F., is highly volatile, has a very acrid taste, is very irritating to the nostrils, and forms salts with alkaline bases called crotonates. It is this principle, probably, which causes the dust and exhalation from the croton seeds sometimes to excite excessive irritation in the mucous surfaces of those who prepare them for expression, or otherwise work among them.

Properties. Croton oil, as found in the shops, varies from a pale yellow to a dark reddish-brown. That imported from India is usually pale, that expressed in

Europe dark like the deepest coloured sherry. Its consistence is rather viscid, and is increased by time. Its smell is faint, but peculiar, its taste hot and acrid, leaving in the mouth a disagreeable sensation which continues for many hours. The oil is wholly soluble in sulphuric ether and oil of turpentine. Its relations to pure alcohol differ somewhat with the variety of the oil. That obtained by expression in England is wholly and readily soluble, forming a solution which is permanent at ordinary temperatures; while the India or pale oil forms an opaque mixture, which becomes clear and uniform upon being heated, but separates on standing into two portions, one consisting of alcohol somewhat diminished in bulk, the other of the oil correspondingly increased in bulk by retaining a portion of the alcohol. It is probable that the difference in colour, and in their relations to alcohol, between the India and English oils, is owing to a change in the kernels from being kept.

Some croton oil examined by M. Dublanc, of Paris, when agitated with ten times its weight of alcohol, was separated into two parts, one of which amounting to 6 per cent. was dissolved by the alcohol, the other remained undissolved, but retained 50 per cent. of alcohol. The latter, upon being repeatedly treated with alcohol, lost all its acrimony; while the portion dissolved was extremely acrid. From these observations it would appear that the acrid and probably active principle of the oil is dissolved by the alcohol; while a bland fixed oil, which constitutes the chief part of it, is not taken up by that liquid. (See *Am. Journ. of Pharm.*, xxv. 56.) It is difficult to reconcile the different results here stated, without supposing that different kinds of oil were employed.

It is thought that croton oil is often adulterated with other fixed oils. The Edinburgh College gives the following test of its purity. "When agitated with its own volume of pure alcohol and gently heated, it separates on standing, without having undergone any apparent diminution." This, however, is not true of the oil expressed in England. The test was intended to detect the presence of castor oil, which would be dissolved by the alcohol, and thus occasion a diminution of the bulk.

We were told by the late Dr. M. Burrough, who was for some time in India, that much of the oil there prepared for exportation, under the name of croton oil, is derived from the seeds of a plant different from the Croton Tiglium. From a parcel of these seeds presented to him by Dr. Burrough, Dr. R. E. Griffith produced a plant which proved to be the Jatropha Curcas, the seeds of which are known by the name of *Barbadoes nuts.* (See *Tapioca.*) This oil, though weaker than the genuine, was said by Dr. Burrough to be an efficient cathartic in the dose of three or four drops. It is stated by Dr. Hamilton that croton seeds are afforded by the *Croton Pavana*, growing in Ava and the Eastern parts of Bengal; and it is highly probable that a portion of the croton oil of commerce is obtained from these seeds. (*Trans. Lin. Soc.*, xiv. 257.) These facts may explain some of the discrepancies in reference to the effects of alcohol above mentioned.

Medical Properties and Uses. Croton oil is a powerful hydragogue purgative, acting, for the most part, when given in moderate doses, with ease to the patient, but in large doses apt to excite vomiting and severe griping pain, and capable, if immoderately taken, of producing fatal effects. It acts with great rapidity, frequently evacuating the bowels in less than an hour, and generally exciting a rumbling sensation in half that period. It possesses also great advantage in the minuteness of the dose, on account of which it may frequently be given when we should fail with more bulky medicines, as in mania, coma, and the cases of children. A drop placed on the tongue of a comatose patient will generally operate. Though long used in India, and known more than a century ago to the Dutch physicians, it did not attract general notice till about 1820, when it was introduced into England by Mr. Conwell. It is chiefly employed in cases of ob-

stinate constipation, in which it often produces the happiest effects after the failure of other medicines; but it may also be advantageously employed in almost all cases in which powerful and speedy purging is demanded. Dropsy, apoplexy, mania, and visceral obstructions, are among the complaints in which it has been particularly recommended. It has recently been employed with great asserted benefit in neuralgia, epilepsy, and spasm of the glottis, and has been supposed to have powers in these affections independent of its purgative property. The seeds are said to have been used with great success in India in amenorrhœa. Applied externally, the oil produces inflammation of the skin, attended with a pustular eruption, and has been used in this way in rheumatism, gout, neuralgia, glandular and other indolent swellings, and in laryngeal and pulmonary diseases. It should be diluted with three parts of olive oil, soap liniment, oil of turpentine, or other convenient vehicle, and applied as a liniment twice or oftener in the twenty-four hours. Sometimes the insusceptibility of the skin is such as to require its application undiluted. For further information on this subject the reader is referred to the *Amer. Journ. of Med. Sciences*, xv. 240. The oil may also be applied externally, in the form of a plaster, made by incorporating one part of it with four parts of lead plaster melted by a very gentle heat. Sometimes it appears to produce inflammation in parts distant from those to which it was directly applied. It has been said that four drops of the oil, applied externally by friction around the umbilicus, will produce a purgative effect; but this is denied by Dr. Barlai, of Tuscany, who states that it is only when the oil is applied to the skin divested of the cuticle that it will operate upon the bowels. (See *Journ. de Pharm.*, 3e *sér.*, xx. 298.)

The dose for an adult is one or two drops, and is most conveniently administered in the form of pill. A very safe and convenient plan is to make two drops into four pills with crumb of bread, and to give one every hour till they operate. The oil may also be given in emulsion. The form of tincture may be advantageously resorted to when a minute quantity of the medicine is required; as it affords the means of readily dividing the dose.

Gen. Ch. Corolla four-petaled. *Calyx* two-leaved. *Capsule* one-celled, opening by pores under the persistent stigma. *Willd.*

Opium is at present generally believed to be derived exclusively from the *Papaver somniferum;* though every species of poppy is capable of yielding it to a greater or less extent, and some authors have indicated the *Papaver orientale* as its real source. The British and French Pharmacopœias unite with our own in recognising only the first-mentioned species.

Papaver somniferum. Willd. *Sp. Plant.* ii. 1147; Woodv. *Med. Bot.* p. 376, t. 138. There are several varieties of this species, of which the two most prominent are distinguished by the titles of the white and black poppy, derived from the colour of their seeds. It is the former which is usually described as the proper opium plant. The *white poppy* is an annual plant, with a round, smooth, erect, glaucous, often branching stem, rising two or three feet in height, and

sometimes attaining five or even six feet in favourable situations. The leaves are large, variously lobed and toothed, and alternately disposed upon the stem, which they closely embrace. The flowers are terminal, very large, and of a white or silver gray colour. In India they appear in February, in Europe and the United States not earlier than June, July, or August. The calyx is smooth, and composed of two leaves, which fall when the petals expand. These are usually four in number; but there is a variety in which the flower is double. The germen, which is smooth and globular, supports a radiated stigma, and is surrounded by numerous short and slender filaments, with erect, oblong, compressed anthers. The capsule is smooth and glaucous, of a rounded shape, from two to four inches in diameter, somewhat flattened at the top and bottom, and crowned with the persistent stigma, the diverging segments of which are arranged in a circle upon the summit. It contains numerous minute white seeds, which, when perfectly ripe, escape through small openings beneath the stigma. In the *black poppy*, the flower, though sometimes white, is usually violet coloured or red, the capsule is somewhat smaller and more globular, and the seeds are of a brown or blackish colour.

All parts of the poppy contain a white, opaque, narcotic juice; but the leaves, when analyzed by M. Blondeau, yielded none of those active principles by which opium is characterized. (*Journ. de Pharm.*, vii. 214.) It is in the capsule that the juice most abounds, and the virtues of the plant chiefly reside. Hence this part is sometimes employed medicinally. (See *Papaver.*) The seeds are destitute of narcotic properties, and are even used as food in many parts of the world. The Romans employed them in the preparation of various dainties. They abound with a bland oil, which may be extracted by expression, and has most of the useful properties of olive oil. It is an article of much importance on the continent of Europe, particularly in France, in the northern departments of which the black poppy is very extensively cultivated for the seed alone. The oil is employed for culinary and pharmaceutic purposes, in painting, and the manufacture of soap, and in other ways as a substitute for olive oil, which is said to be frequently adulterated with it. The poppy does not appear to elaborate the milky fluid in which its narcotic properties reside, before a certain period of its growth; for we are told that, in Persia, the young plants which are pulled up to prevent too thick a crop are used as pot-herbs; and the μηκων of the Greeks, which is believed to be identical with the Papaver somniferum, is said by Hippocrates to be nutritive.

Though generally believed to be a native of Asia, this species of poppy grows wild in the South of Europe, and even in England, whither its seeds are supposed to have been brought at a very early period. It was cultivated by the ancient Greeks, and is mentioned by Homer as a garden plant. It is at present cultivated very extensively in India, Persia, Egypt, and Asiatic Turkey, for opium; and in several parts of Europe, especially in France, not only for this product, but also for the seed and capsules. In this country it is found only in our gardens as an ornamental flower.

The process for procuring opium from the poppy, as practised by the modern inhabitants of India and Persia, according to the reports of Kerr and of Kœmpfer, is very nearly the same with that described by Dioscorides as employed in his own times, about eighteen hundred years since; and the accounts of Bélon, Olivier, and Texier, as to the modes of collection in Asia Minor, are not materially different. As the capsules abound most in the narcotic juice, it is from these that the opium is procured. According to Texier, a few days after the fall of the flower, men and women proceed to the fields, and make horizontal incisions in the capsule, taking care not to penetrate its cavity. A white juice exudes, and appears in the form of tears upon the edges of the incisions. The

field is left in this state for twenty-four hours, after which the juice is scraped off by means of large blunt knives. A portion of the epidermis of the capsule is also removed, and constitutes about one-twelfth of the whole product. Each poppy-head affords opium but once. Thus collected, the opium is in the state of an adhesive and granular jelly. It is placed in small earthen vessels, where it is beaten, and at the same time moistened with saliva. When of a proper consistence, it is wrapped in leaves and sent into the market. (*Journ. de Pharm.*, xxi. 196.) Considerable quantities of good opium have been obtained in England by scarifying the capsules of the poppy.* Similar success has been met with in France; and the drug obtained by incisions, in both countries, has been found nearly if not quite equal to that imported from the East. In the *Dictionnaire des Drogues* it is stated that a specimen of opium, collected in this way in the vicinity of Provins, gave sixteen per cent. of the active principle, while a good commercial specimen, examined by M. Petit, afforded only eight per cent.

Another method of extracting the virtues of the capsules is to select such as have ceased to yield their juice by exudation, to beat them with a small proportion of water, and inspissate the liquid thus obtained by artificial heat. The ancient Greeks were acquainted with both processes, as appears from the writings of Dioscorides. The term οπιον, derived from οπος, juice, they applied to the substance procured by incisions, which answers precisely to the modern opium. The inspissated expressed juice they called μηκωνιον, from μηκων, the name of the plant. Tournefort states that it is the latter preparation which is exported from Turkey as opium, the former being much more valuable, and therefore retained in the country for the use of the great and wealthy. This error has been copied by many writers on the materia medica; and, till within a comparatively few years, opium was generally believed to be an extract obtained by evaporating either the expressed juice, or a decoction of the capsules.

Commercial History. Commerce is supplied with opium chiefly from Hindostan, Persia, Egypt, and the Asiatic dominions of Turkey. Immense quantities are produced in the Indian provinces of Bahar and Benares, and in the more interior province of Malwa. The opium of Hindostan is distributed ex-

* So early as the year 1796, a premium was awarded by the Society for the Encouragement of Arts, to Mr. Ball, for a specimen of British opium; and in 1823, Messrs. Cowley and Stains collected 196 pounds, which sold for nearly seven dollars a pound, from little more than twelve acres of land. This product, however, was by no means equal to that obtained in Scotland by Mr. John Young. From one acre of ground planted with poppies and potatoes, he procured fifty-six pounds of opium, valued at 450 dollars, while the whole expense was more than repaid by the potatoes, and the oil expressed from the seeds. For papers on the subject of the cultivation of the poppy in England, see *Edin. Philosoph. Journ.*, vol. i. p. 258, and the *Quarterly Journal of Science*, vol. iv. p. 69.

M. Aubergier has cultivated opium in France, with encouraging results. Instead of allowing the juice after the incision to inspissate on the capsule, he collected it immediately, and dried it by artificial heat. One workman collected in a day 300 grammes (9·64 troy ounces) of juice, which yielded one-quarter of its weight of opium. The product differed in strength very greatly, according to the variety of poppy used; the yield of morphia having varied from 3 to 17·8 per cent. He gives the preference to the *purple poppy*. (*Ann. de Thérap.*, A. D. 1852, p. 29.) See also the same work (A. D. 1853, p. 1) for an elaborate report on M. Aubergier's Memoir, by a committee consisting of MM. Rayer, Orfila, and others.

In Armenia, where opium is largely produced, four varieties of seeds are used, the white, yellow, black, and sky-blue. The flower produced by the white seeds is white, that by the yellow is red, that by the black is black, and that by the sky-blue, is deep purple. The white and sky-blue seeds yield large somewhat oblong capsules, like citrons in shape; the yellow and black, small and round capsules. For an extent of ground forty paces square, forty drachms of seeds are required. Each head yields about a grain of opium. The operators, not accustomed to the work, are apt to become intoxicated or stupefied during the period of harvest. (Gaultier de Claubry, *Journ. de Pharm.*, 3e sér., xiii. 105.)

tensively through continental and insular India, where it is habitually employed in the place of spirituous liquors. Great quantities are also sent to China, into which it finds an easy entrance, notwithstanding prohibitory laws. Much was formerly imported by the East India Company into England, through which a small portion reached our own country; but it was so far inferior to that from Turkey, that it was at length excluded from the market, and none is now brought directly from the East. The great demand for it in the Indian Archipelago and in China, and its consequent high price, have probably contributed even more than its reputed inferiority to this result. Indeed, Ainslie explicitly states that India opium is inferior to none; and it is probable that the specimens from which the description was drawn up that was formerly current among authors upon the materia medica, were the refuse of the Eastern market. We know that the drug was formerly very much and variously adulterated by the natives. Among the impurities mentioned by authors are the extract of the poppy procured by decoction, the powdered leaves and stems of the plant made into a paste with mucilage, oil of sesamum, catechu, and even cow-dung. But a more careful superintendence by the officers of the Company has resulted in a great improvement of the India opium. Of that produced in Persia, very little is brought to this country; and it is scarcely known in our market as a distinct variety. Much was formerly produced in Upper Egypt, especially in the district of ancient Thebes, which was supposed to yield it in greatest perfection. It was in fact for a long time generally known by the name of *Opium Thebaicum*, and laudanum is still frequently directed in prescriptions as *Tinctura Thebaica*. Its cultivation has recently been again introduced into Egypt; and considerable quantities are now exported.

Turkey opium is produced in Anatolia, and shipped chiefly from the port of Smyrna. It is brought to the United States, either directly from the Levant, or indirectly through different European ports. From the treasury returns for the years from 1827 to 1845 inclusive, according to a table prepared by Dr. J. B. Biddle, and published in the *American Journal of Pharmacy* for April, 1847, it appears that the average value of the annual importations for the period referred to was from Turkey 128,137 dollars, from England 13,744, from France 4,470, and from all other places 6,607 dollars. Of this amount so much was exported as to leave for the average annual consumption of the country the value of 66,809 dollars. Turkey opium usually comes to us in masses of irregular size and shape, generally more or less flattened, covered with leaves, or the remains of leaves, and with the reddish capsules of some species of *Rumex*, which are said to be absent in the inferior kinds, and may therefore be considered as affording some indication of the purity of the drug. We may account for this circumstance upon the very probable supposition, that these capsules are removed during the operation which the masses sometimes undergo in the hands of the merchants, after leaving those of the cultivators. We are told by the French writers that extensive frauds are practised at Marseilles in this branch of commerce. The opium taken thither from the Levant is first softened, and then adulterated with various matters which are incorporated in its substance. To use a strong expression of M. Guibourt, they make the opium over again at Marseilles. Our traders to the Mediterranean would do well to bear this assertion in mind. According to Dr. A. T. Thomson, one-fourth part of Turkey opium generally consists of impurities. Sand, ashes, the seeds of different plants, extracts of the poppy, *Lactuca virosa*, *Glycyrrhiza glabra*, and *Chelidonium glaucum*, gum Arabic, tragacanth, salep, aloes, even small stones, and minute pieces of lead and iron, are mentioned among the substances employed in the sophistication of the drug. Mr. Landerer, of Athens, was informed by a person who had been

engaged in the extraction of opium, that grapes freed from their seeds and crushed, were almost universally mixed with the poppy juice, and that another adulteration consisted of the epidermis of the capsules and stem of the plant, pounded in a mortar with the white of eggs. (See *Am. Journ. of Pharm.*, xv. 238.) In England a sophisticated opium was a few years since prepared, so nearly resembling good Turkey opium in appearance, that by the eye alone it was difficult to detect the fraud, and yet wholly destitute of the active principle of this drug. Portions of it were sent into the markets both of France and this country. It was probably the genuine drug, deprived of its morphia by some process which did not materially disturb the visible arrangement of its particles.* (*Am. Journ. of Pharm.*, x. 261.)

* The great importance of opium renders it desirable that all its commercial varieties should be accurately described, and their relative value so far as possible ascertained. The following statement has been drawn up from the most recent published accounts of the drug, and from the personal observations of the author. The papers of Guibourt in France, Christison in Great Britain, and Merck and Martius in Germany, have been consulted. (See *Journ. de Pharm.*, xvii. 714, and xxi. 542; and *Annalen der Pharm.*, xviii. 79, and xxiv. 56.)

The varieties of this drug may be arranged, according to the countries in which they are produced, under the heads of *Turkey*, *Egyptian*, *India*, and *Persia opium*.

I. TURKEY OPIUM. This title belongs to the opium produced in the Turkish province of Anatolia, and exported from Smyrna and Constantinople. According to some authorities, there is no essential difference between the parcels of the drug brought from these two ports. Others maintain that they are distinct varieties, differing in their interior structure, and probably also in the precise place of their production, and the mode of their collection. The truth probably is, that most of the opium shipped at Constantinople is produced in the northern parts of Anatolia, while that from Smyrna is collected in the provinces more convenient to the latter city; and, though it is possible that an identical drug may be occasionally brought from the two ports, yet there seems to be good ground in general for arranging it under different varieties, as derived from these different sources.

1. *Smyrna Opium.* This is the variety which is, beyond all comparison, most abundant in our markets: and it is from this that the ordinary descriptions of opium are drawn up. It comes to us in masses of various size, usually from half a pound or somewhat less to a pound in weight, sometimes, though rarely, as much as two or even three pounds, originally, perhaps, of a globular form, but variously indented, and rendered quite irregular in shape, by the pressure to which they have been subjected, while yet soft, in the cases which contain them. Sometimes they are even pressed out into flat cakes. As brought into market, the lumps are usually hard on the outside, but still soft within. They are covered externally with the remains of leaves, and with the reddish capsules of a species of Rumex, which have no doubt been applied in order to prevent the surfaces from adhering. Notwithstanding, however, this coating, the masses sometimes stick together, and two or more become consolidated into one. In this way the fact may be accounted for, that the seeds of the Rumex are occasionally found in the interior of the masses. In the finer parcels of Smyrna opium, the colour internally is light-brown; in the inferior it is darker. A peculiar character of this variety is, that when a lump of it is cut into and then carefully torn, numerous minute shining tears are observable, particularly under a microscope; bearing some resemblance to small seeds, but readily distinguishable by pressure between the fingers. They are undoubtedly formed from the drops of juice which escape from the incisions in the capsules, and which, according to Bélon, are allowed to concrete before they are removed. From the account of the same author it appears that, after the juice has been collected, it is not subjected to the process of kneading or beating, as in the case of other varieties of opium; so that the tears preserve their original shape in the mass. It is probably owing to the peculiar mode of collecting Smyrna opium, that minute pieces of the skin of the poppy capsules are found intermingled in the mass; these being separated in the process of removing the adhering tears. In the finer specimens of Smyrna opium, these fragments of the capsules are the only impurities. This variety of the drug is of very different qualities, the finest kinds yielding, according to Merck, as much as 13 per cent. of pure morphia, while from some very bad parcels he could not procure more than 3 or 4 per cent. In these inferior specimens the colour is darker, the smell is often musty, and there is very generally more or less mouldiness both upon the surface, and in the interior of the masses, indicating perhaps too much moisture in the opium originally, or its subsequent exposure to an injurious degree of dampness. Good Smyrna opium ought to yield 10 or 11 per cent.

Opium is regarded as inferior when it has a blackish colour; a weak or empyreumatic smell; a sweet or slightly nauseous and bitter taste; a soft, viscid, or greasy consistence; a dull fracture; or an irregular, heterogeneous texture, arising from the intermixture of foreign substances. It should not impart a

of morphia. Dr. Christison, however, states that he has not been able to procure more than 9 per cent. from the finest Smyrna opium.*

2. *Constantinople Opium.* Most of the Constantinople opium is in lumps from half a pound to two and a half pounds in weight, and scarcely distinguishable in exterior appearance from those of the former variety, being equally irregular in shape, and in like manner covered with the capsules of the Rumex. It differs, however, strikingly from the Smyrna opium in its interior constitution, being, according to Merck, wholly destitute of the tears which characterize that variety. This would indicate some difference in the mode of collecting and preparing the juice. In the case of the Constantinople opium, it is probably either removed from the capsules before concretion, or subjected to pressure afterwards. Merck says that he has not discovered, in this variety, those minute portions of the poppy capsules which are usually present in the Smyrna opium. The average quality of the Constantinople opium, as above described, is about equal to that of the drug from Smyrna; but it appears to be occasionally purer; as Merck obtained from one specimen as much as 15 per cent. of pure morphia. Notwithstanding what has been above stated, we are not yet in possession of facts to prove that this is not, as some have supposed it to be, the better sort of Smyrna opium selected and sent to the capital.

Guibourt describes another variety of Constantinople opium of much inferior character. "It comes," he observes, "in small flattened cakes, sufficiently regular and of a lenticular shape, from two to two and a half inches in diameter, and always covered with a poppy leaf, the midrib of which divides the surface into two equal parts. It has an odour similar to that of the preceding variety, but feebler, and it blackens and dries in the air. It is more mucilaginous than Smyrna opium, and contains only half as much morphia." These characters are obviously those of Egyptian opium; and, though the parcels which came under the notice of Guibourt may have been imported directly from Constantinople, it is highly probable that they were originally from Alexandria. Mr. Stettner, of Trieste, though well acquainted with the opium commerce of that port, admits no such Constantinople opium as that described by Guibourt. (*Annal. der Pharm.*, xxiv. 65.)

II. EGYPTIAN OPIUM. This is in flat roundish cakes, of various dimensions, sometimes as much as six inches in diameter, and a pound in weight, usually, however, much smaller, and sometimes not weighing more than half an ounce. These cakes are either wrapped in a poppy leaf, so placed that the midrib divides the surface into two equal parts, or exhibits vestiges of such a covering. Occasionally the brown colour of the opium is seen through the leaf, and the surface appears as if uncovered, while the leaf is still present. This variety of opium is always destitute of the Rumex capsules, and differs from the Smyrna opium also in being brittle instead of tenacious, and equally hard in the centre as at the surface of the mass. Its fracture is conchoidal and of a waxy lustre, and small fragments of it are translucent. Its colour is usually redder than that of Smyrna opium, though it is sometimes dark. Some of the pieces, on exposure to the air, become damp and sticky on the outer surface, indicating the fraudulent addition of some deliquescent substance. The odour is similar to that of Smyrna opium, but weaker. It is an inferior variety; as the best of it, examined by Merck, yielded only 6 or 7 per cent. of morphia; and a specimen of it was found by Mr. J. Evans, of Philadelphia, to contain not more than 3·55 per cent. Egyptian opium, therefore, should never be dispensed by the apothecary, or employed in the preparation of his tinctures; as the prescription of the physician is based upon the strength of good Smyrna opium, which is about twice that of the Egyptian.

III. INDIA OPIUM. Little if any of this opium reaches our market. There appear to be two chief varieties of it, one produced in Bahar and Benares, in the Bengal Presi-

* According to Landerer, little of the opium is produced in the immediate neighbourhood of Smyrna; the greater portion being brought to that port, on the backs of camels, from a distance of from ten to eighteen days' journey. (*Journ. de Pharm., 3e sér.*, xxiii. 33.) The same writer states that the opium is chiefly prepared at Kara Chissar, near Magnesia. The incisions are generally made before sunrise. The juice is partly caught in mussel-shells, and dried in the sun. This is considered the best. Every evening the juice which has dried upon the capsules is scraped off, with a portion of the epidermis. The poppy is then cut down, and stripped of its leaves, which are boiled in water; and the liquid is evaporated to the consistence of an extract. With this the inspissated juice is incorporated, and the mixture is then formed into cakes, wrapped in poppy-leaves, and placed on shelves to dry. (See *Am. Journ. of Pharm.*, xxiii. 251.) It is very evident, from the interior structure of the *best Smyrna opium*, that it has not been prepared in the way described by Landerer; though his account is probably true in reference to inferior varieties of the drug.—*Note to the tenth edition.*

deep-brown colour to the saliva, nor leave a dark uniform trace when drawn over paper, nor form with water a thick viscid solution.

Properties. Good opium has a peculiar strong narcotic odour, and a bitter, somewhat acrid taste. When long chewed it excites much irritation in the lips

dency, and called *Bengal opium*, the other in the interior provinces, and designated by the name of *Malwa opium*.

1. *Bengal Opium.* For a minute account of the cultivation and preparation of this variety of opium, the reader is referred to elaborate papers by Dr. Eatwell, of Calcutta, contained in the eleventh and twelfth volumes of the *London Pharmaceutical Journal and Transactions*, an abstract of which will be found in the *Am. Journ. of Pharm.*, xxiv. 118, and in the last edition of Pereira's *Materia Medica* (vol. ii. p. 1009, Am. ed.). Bengal opium is identical with the variety sometimes called *Patna opium*. It is in round balls, weighing three pounds and a half, invested by a coating half an inch thick, composed of agglutinated leaves and poppy-petals. The interior of the mass is of a brownish-black colour, of the consistence of a stiff paste, and possessed in a high degree of the characteristic odour and taste of opium. The proportion of active matter in this opium varies somewhat with the season, and in the different specimens. From a table given by Dr. Eatwell, it appears that the percentage of morphia varies from 2·17 to 3·67, and that of narcotina from 3·85 to 5·70. Prof. Procter found a specimen of Patna opium to yield about 5 per cent. of morphia. (*Am. Journ. of Pharm.*, xxi. 194.) It is, therefore, much inferior to the best Smyrna opium in its yield of morphia, while it is richer in narcotina. Yet Christison states that all the India opium which he has seen is exempt from the mixture of leaves, seeds, and fragments of poppy capsules so abundant in Smyrna opium. Its inferior character is in some degree probably owing to the juice, after collection, being kept for some time before it is made up, and consequently undergoing fermentation.

The India opium examined by Dr. A. T. Thomson was apparently of inferior character. As described by that author, it was in round masses, covered with the petals of the poppy in successive layers, to the thickness of nearly one-fourth of an inch. It had a strong empyreumatic smell, with little of the peculiar heavy odour of Turkey opium. Its taste was more bitter and equally nauseous, but less acrid. Its colour was blacker, and its texture, though as tenacious, was less plastic. It was more friable, and when triturated with water, was wholly suspended or dissolved, leaving none of that plastic residue which is afforded by the other variety. It yielded to Dr. Thomson more narcotina than Turkey opium, but only about one-third the quantity of morphia. All these are the characters of an extract of the poppy heads, rather than of their inspissated juice. The absence of the plastic principle analogous to caoutchouc is strong evidence in favour of this view of its nature; for it is obvious that water would not extract this principle from the capsules, while it is hardly probable that the juice is destitute of it. Besides, the strength indicated by Dr. Thomson is very nearly the same with that of the extract of the capsules prepared in France. The Bengal opium is at present a superior drug to that here described, though still inferior to the Smyrna opium.

There is a variety of Patna or Bengal opium, called *garden Patna opium*, which was described in the fifth edition of this work, on the authority of Dr. Christison, as Malwa opium. Dr. Christison has subsequently ascertained its true origin. It is prepared in Bahar with peculiar care, from juice which has not been suffered to undergo fermentation. It is in cakes three or four inches square, and about half an inch thick, which are packed in cases with a layer of mica between them. These cakes are without covering, hard, dry, and brittle, of a uniform shining fracture, and not unlike an extract in appearance. The colour is sometimes almost black, and sometimes of a light-brown, not unlike that of Egyptian opium. Dr. Christison states that it is much superior to the globular Bengal opium, and that some specimens are little inferior to Turkey opium in the proportion of morphia.

2. *Malwa Opium.* This is in flat, roundish cakes, five or six inches in diameter, and from four to eight ounces in weight. They are commonly quite hard, dry, and brittle, of a light-brown colour, a shining fracture, a compact homogeneous texture, and free from mechanical impurities. The quality is superior to that of common Bengal opium. (*Christison's Dispensatory.*) A specimen of Malwa opium described by Dr. Carson (*Am. Journ. of Pharm.*, xxi. 195) broke with a short rough fracture, which was of a blackish-brown colour, here and there showing irregular oily spots. Prof. Procter obtained from it 9¼ per cent. of morphia.

IV. PERSIA OPIUM. A variety of opium under this name has sometimes existed in the markets of London, and has even found its way to this country, though it is very rare. It is described as being in cylindrical pieces, about three and a half inches long and half

and tongue, and even blisters the mouth of those unaccustomed to its use. Its colour is reddish-brown or deep-fawn; its texture compact; its sp. gr. 1·336. When drawn over paper it usually leaves an interrupted trace of a light-brown colour. It is often soft in the interior of the mass, and in this state is tenacious; but when exposed to the air it gradually hardens, and ultimately becomes brittle, breaking with a shining fracture, and affording, when pulverized, a yellowish-brown powder, which becomes adhesive upon a slight elevation of temperature. It readily inflames upon the application of a lighted taper. It yields its virtues to water, alcohol, and diluted acids, but not to ether. To all these menstrua it imparts a deep-brown colour. Alcohol dissolves about four-fifths of it. Pelletier states that the proportion taken up by water varies in all specimens. He never found the quantity of extract prepared with cold water to exceed 12 parts out of 16. (*Journ. de Pharm.*, Nov. 1832.)

Much attention has been devoted to the chemical constitution of opium; and very interesting results have been obtained. It was by their researches into the nature of this substance that chemists were led to the discovery of those vegetable alkaloids, which, as the active principles of the plants in which they are found, have attracted so much attention, and been applied so advantageously in the treatment of disease. To Sertürner, an apothecary at Eimbeck, in Hanover, certainly belongs the credit of having opened this new and most important field of experiment. In the year 1803, M. Derosne made known the existence of a crystallizable substance which he had discovered in opium, and which he erroneously believed to be the active principle. In the following year, Seguin discovered another crystallizable body, which subsequent experience has proved to be the true narcotic principle of opium; but he did not fully investigate its nature, and no immediate practical advantage was derived from his excellent analysis. About the same time Sertürner was engaged in a similar investigation, the results of which, very analogous to those obtained by Seguin, were published in a German journal, without, however, attracting general attention. In this state the subject remained till the year 1817, when Sertürner announced the existence of a saline compound in opium, consisting of a peculiar alkaline principle united with a peculiar acid, and clearly demonstrated the precise nature of a substance, which, though before discovered both by Seguin and by himself, had been hitherto but vaguely known. To the alkaloid, in which he correctly conceived the narcotic powers of the opium to reside, he gave the name of *morphium*, which has been subsequently changed to *morphia*, in order to render it analogous to the titles of the other alkalies. The acid he called *meconic*, a term derived from the Greek name of the poppy. The correctness of the statements of Sertürner was confirmed by Robiquet, who also satisfactorily demonstrated that the substance obtained by Derosne, and called by him the *salt of opium*, was a principle altogether distinct from morphia, though supposed to possess

an inch thick, wrapped in glossy paper, and tied with a cotton thread. It is of a uniform consistence, but exhibits, nevertheless, under the microscope, small agglutinated tears, much less than those of the Smyrna opium. It has the liver-brown colour of Egyptian opium, a virose, musty odour, and a very bitter taste; and, like Egyptian opium, softens in a moist atmosphere. It is said to have been brought to England from Trebizond on the Black Sea; but its origin is not known. It is of inferior quality. From the report of a trial in the city of New York, published in the *Journal of Commerce*, it appears that a parcel of Persia opium imported into that city from London in August, 1835, was in small round balls, and contained only 3 per cent. of morphia.

It is highly important that the real value of these commercial varieties of opium should be known to the physician and apothecary; as otherwise, there can be no certainty in relation to the strength of the preparations which may be made from them. In the preparation of laudanum and the other tinctures into which opium enters, it is understood that the drug employed should have the average quality of good Smyrna opium. The inferior kinds should be used only for the extraction of morphia.

very considerable influence over the system. In the belief of its narcotic powers, Robiquet denominated it *narcotin*, a title which it still retains. Several other peculiar principles have since been discovered; though it is difficult to resist the impression, that some of them may be the result of the processes to which opium is submitted for their extraction. According to the views of its constitution at present admitted, opium contains, 1. morphia; 2. narcotin or narcotina; 3. codeia; 4. paramorphia; 5. narcein; 6. meconin; 7. porphyroxin; 8. meconic and sulphuric acids; 9. a peculiar acid, not yet fully investigated; 10. extractive matter; 11. gum; 12. bassorin; 13. a peculiar resinous body insoluble in ether and containing nitrogen; 14. fixed oil; 15. a substance resembling caoutchouc; 16. an odorous volatile principle; besides lignin, and a small proportion of acetic acid, sulphate of lime, sulphate of potassa, alumina, and iron. Besides these principles, Pelletier announced the discovery of another which he called pseudomorphia, but which appears to be only an occasional constituent of opium. (See *Journ. de Pharm.*, xxi. 575.)* In relation to their optical properties, all the

* Besides the components of opium mentioned in the text, notice has been given of the discovery of two other alkaloids, named respectively *papaverine* (*papaverina*) and *opianine* (*opiania*), of which we shall here give a brief notice; though further and repeated experiments will be necessary to establish their claims.

1. *Papaverina* (*papaverine*). The discovery of this alkaloid was announced by Dr. G. Merck. It is crystallizable in needles, insoluble in water, very sparingly soluble in cold alcohol or ether, more soluble in these liquids boiling hot, and deposited by them on cooling. With acids it forms salts most of which are very sparingly dissolved by water. The muriate crystallizes with extraordinary facility. The alkaloid is readily dissolved by moderately concentrated muriatic acid, from which, on the addition of more acid, the muriate separates, assuming the form of an oily layer at the bottom of the vessel, which is readily converted on standing into a mass of acicular crystals. These crystals are very sparingly soluble in cold water. The muriate yields with chloride of platinum a yellow precipitate which is insoluble in boiling water or alcohol. (See *Am. Journ. of Pharm.*, ix. 311.) Papaverina is prepared by precipitating the aqueous infusion of opium with soda, exhausting the precipitate with alcohol, evaporating the tincture to dryness, treating the residue with a dilute acid, filtering, precipitating by ammonia, dissolving the precipitate in muriatic acid, mixing with the solution the acetate of soda, and treating with boiling ether the resulting precipitate. The ethereal solution deposits the papaverina on cooling. A characteristic property of this alkaloid is that its crystals, when moistened with concentrated sulphuric acid, acquire a dark-blue colour. It consists of nitrogen, carbon, hydrogen, and oxygen; its formula being $NC_{40}H_{21}O_8$. (*Chem. Gaz.*, March 15, 1850, from *Liebig's Annalen.*)

2. *Opiania* (*opianine*). This was found by Dr. Hinterberger in some supposed narcotina, which had been obtained by Engler, an apothecary of Vienna, from a parcel of Egyptian opium which he was working for morphia. An infusion of the opium was precipitated by ammonia, and the precipitate, having been washed first with water and then with cold alcohol, was dissolved in hot alcohol, and decolorized by animal charcoal. A crystalline mass was thus obtained consisting apparently of morphia and narcotina. By repeated solutions in hot alcohol and crystallization, the former was separated, remaining in the alcohol, while the supposed narcotina was obtained in crystals. These, upon being examined by Dr. Hinterberger, proved to be a new alkaloid, to which he gave the name of *opianine*. It is in long, colourless, transparent needles, belonging to the prismatic system. When precipitated by ammonia from the solution of the muriate, it is in the form of a soft white powder. It is without smell, and in alcoholic solution has a strong and durable bitter taste. At the temperature of 212° F. it remains unchanged. It is insoluble in water, and requires for solution a large quantity of boiling alcohol, from which it is entirely thrown down, upon cooling, in the state of crystals. In alcoholic solution it has a strong alkaline reaction; and from this solution both opiania itself and its salts are thrown down by alkalies. Concentrated sulphuric acid dissolves without changing it; nitric acid renders it yellow, and, if added to its sulphuric acid solution, blood-red, but after a short time changing to light-yellow. Its formula, according to Hinterberger, is $N_2C_{66}H_{36}O_{21}$. From experiments performed with it on the lower animals, it has been inferred to be powerfully narcotic, and to resemble morphia in its action. About one-tenth of a grain of each of these alkaloids was given to two cats, one to one cat, and the other to the other, with very similar effects, which were decidedly narcotic, and continued for a considerable time, but had ceased at the expiration of 24 hours, without fatal effects. (*Chem. Gaz.*, Dec. 1, 1852, p. 444, from the *Proceedings of the Acad. of Sci. at Vienna*, vii. part 3.)—*Note to the tenth edition.*

organic bases of opium have the property of deviating to the left the rays of polarized light. (MM. Bouchardat and Felix Boudet, *Journ. de Pharm.*, 3*e sér.*, xxiii. 294.)

Of the principles above mentioned *morphia* is by far the most important. It is generally admitted to exist in opium united with meconic acid in the state of meconate, and to a certain extent also as a sulphate. Of morphia and its preparations we shall treat at large under another head. (See *Morphia.*)

Narcotina or *narcotin* receives one or the other of these names according as it is considered alkaline or neuter; they who rank it among the alkalies giving it the former name, they who deny it such a position, the latter. It exists in opium, chiefly, at least, in the free state, and is left behind in considerable quantity when the drug is macerated with water. It is white, tasteless, and inodorous; and crystallizes in silky flexible needles, usually larger than the crystals of morphia, fusible at a moderate elevation of temperature, insoluble in cold water, soluble in 400 parts of boiling water, in 100 parts of cold and 24 of boiling alcohol which deposits it upon cooling, and very soluble in ether. The fixed and volatile oils, and the diluted acids also dissolve it. As it exerts no alkaline reaction upon vegetable colours, and does not prevent the acids from reddening litmus paper, there would appear to be some reason for denying it the rank of an alkali. But it unites with some of the acids forming definite compounds, which may be procured in a separate state; and Robiquet obtained the sulphate and muriate of narcotina well crystallized. (*Journ. de Pharm.*, xvii. 639, and xix. 59.) Hence many chemists, among whom is Berzelius, consider it alkaline; and, perhaps, this view of it is the most convenient. It must be admitted, however, to have a very feeble neutralizing power. With acetic acid it does not appear to form a permanent combination; for, though dissolved by cold acetic acid, it is separated by heating the solution. Narcotina consists of nitrogen, carbon, hydrogen, and oxygen; and its received formula is $NC_{48}H_{24}O_{15}$. It may be distinguished from morphia by its insipidity, solubility in ether, and insolubility in alkaline solutions, by not affecting vegetable colours, by assuming a yellowish instead of a blood-red colour under the action of strong nitric acid, by not decomposing iodic acid, and by not producing a blue colour with the salts of iron. It is however, reddened by a mixture of nitric and sulphuric acids. Hence, if to a mixture of it with strong sulphuric acid a small piece of nitre be added, a deep blood-red colour is produced; while morphia, under the same circumstances, yields a brownish or olive-green colour. It gives a greasy stain to paper when heated upon it over a candle. Heated with an excess of sulphuric acid and deutoxide of manganese, it is converted into an acid called *opianic acid*, and into a substance of feeble alkaline properties, which has received the name of *cotarnine* (*cotarnia*). (*Journ. de Pharm.*, 3*e sér.*, vi. 99.) When subjected to distillation with potassa, it yields a colourless volatile liquid having alkaline properties, with the strong smell of herring-pickle together with that of ammonia. This is thought to be a peculiar alkaloid, and has received the name of *propylamine.* (Wertheim, *Pharm. Cent. Blatt*, June 1, 1850, p. 421, and Dec. 17, 1831, p. 918.)* Water extracts narcotina partially from opium, in consequence of the acid which the latter contains, either free or combined with

* There would seem, from the observations of Wertheim and Hinterberger, to be four homologous modifications of narcotina, having a fixed relation to each other in composition, the number of eqs. of nitrogen and oxygen being the same in all, while those of carbon and hydrogen increase by 2 eqs. in regular progression. Thus 1. *normal narcotina* (Hinterberger) has the formula $NC_{42}H_{21}O_{14}$; 2. *methylic narcotina* (Wertheim) $NC_{44}H_{23}O_{14}$; 3. *æthylic narcotina* (Wertheim) $NC_{46}H_{25}O_{14}$; and 4. *propylic narcotina* (Wertheim) $NC_{48}H_{27}O_{14}$. Another interesting point is that each of these yields a peculiar volatile alkali by distillation with potassa; and the several products bear to each other the same chemical relation as exists between the fixed alkaloids from which they are derived. They are *ammonia* from

the narcotina. It is usually obtained mixed with morphia in the processes for procuring that principle; and may be separated by the action of sulphuric ether, which dissolves it without affecting the morphia, and yields it upon evaporation. It may also be obtained by digesting opium in sulphuric ether, and slowly evaporating the ethereal solution, which deposits crystals of narcotina. Another mode of procuring it is to treat opium, which has been exhausted by previous maceration in water, with dilute acetic acid, to filter the solution, precipitate by an alkali, wash the precipitate with water, and purify it by solution in boiling alcohol, from which it crystallizes as the liquid cools. Should it still be impure, the solution in alcohol and crystallization may be repeated.

The proportion of this principle found in opium varies extremely in the different varieties, and in different specimens of the same variety. Thus in Smyrna opium it has been found, according to different observers, in quantities varying from 1·30 per cent. (*Schindler*) to 9·36 per cent., in one of the specimens examined by Mulder.

Though narcotina itself is tasteless, its salts are very bitter, even more so than those of morphia. (*Berzelius.*) Their solution reddens litmus, and affords precipitates with the alkalies and infusion of galls. They have not been very accurately investigated. It has already been stated that Robiquet obtained the sulphate and muriate crystallized.

Different opinions have been advanced relative to the action of narcotina on the system. Derosne believed it to be the active principle of opium; though, upon experimenting with it, he obtained effects but little stronger than those produced by an equal dose of opium itself. Magendie found it to act powerfully upon dogs. One grain dissolved in oil was sufficient to throw the animal into a state of stupor, terminating in death in twenty-four hours. This stupor was wholly different from the composed sleep produced by morphia and its preparations. He inferred that, while the latter principle exercises the remedial, anodyne, and soporific virtues of opium, the injurious excitant operation of the medicine is ascribable to the narcotina. Both Derosne and Magendie found its unpleasant effects to be modified or prevented by its conjunction with acetic acid. According to Magendie, twenty-four grains, dissolved in vinegar, may be given to a dog without destroying life. M. Baily prescribed it in the dose of sixty grains, both in the solid state and dissolved in muriatic acid, without observing from it any sensible effect. In the same state, Orfila found that it might be taken by man in very large doses with impunity; and thirty grains of it, dissolved in acetic acid, produced no effect upon several patients to whom it was administered. Upon dogs, he informs us that it is without action when dissolved in nitric or muriatic acid; but held in solution by acetic or sulphuric acid, or by olive oil, thirty or forty grains of it were sufficient to produce fatal effects. A singular circumstance noticed by the same experimenter was, that the solution in acetic or sulphuric acid occasioned violent excitement; while the contrary condition uniformly resulted from the use of the solution in olive oil. On the whole, we may conclude that narcotina, either in the solid form or dissolved in acids, is not possessed of any considerable narcotic powers; and that the effects of a narcotic character which have been attributed to it, have probably arisen from the employment of a preparation not entirely freed from other principles contained in the opium. Dr. O'Shaughnessy, Professor of Chemistry in the Medical College

the first, *methylamine* from the second, *æthylamine* from the third, and *propylamine* from the fourth. The last of these volatile alkaloids has been referred to in the text as having the smell of herring-pickle. It is said to be produced also by distilling ergot with potassa. Methylamine was procured by Wertheim The other products are, we believe, thus far hypothetical. (*Pharm. Cent. Blatt*, Dec. 17, 1851, p. 918; and *Journ. de Pharm.*, 3*e sér.*, xxiii. 154.)—*Note to the tenth edition.*

of Calcutta, recommends narcotina very highly in intermittent fever, and believes that he has discovered in it even stronger antiperiodic properties than those of quinia. In the cases reported by him, it was employed in combination with muriatic acid. Given in this form, though powerfully febrifuge, it was found not to produce narcotic effects, not to constipate the bowels, and never to occasion that distressing headache and restlessness which sometimes follow the use of quinia. It proved, moreover, powerfully sudorific. It was given in doses of three grains, three times a day. Dr. O'Shaughnessy was induced to recommend its employment to his medical friends in India, from a knowledge that it had proved effectual in mild agues, in the hands of Dr. Roots and Mr. Jetson in England.*

Codeia was discovered in 1832 by Robiquet in the muriate of morphia prepared according to the process of Gregory. It exists in opium combined like morphia with meconic acid, and is extracted along with that alkali in the preparation of the muriate. (See *Morphia.*) When the solution of the mixed muriates of morphia and codeia is treated with ammonia, the former alkali is precipitated, and the codeia, remaining in solution, may be obtained by evaporation and crystallization. It may be purified by treating the crystals with hot ether, which dissolves them, and yields the codeia in colourless crystals by spontaneous evaporation. This alkaline product melts at 300° without decomposition. It is soluble in water, which takes up 1·26 per cent. at 60°, 3·7 at 110°, and 5·9 at 212°. When added in excess to boiling water, the undissolved portion melts and sinks to the bottom, having the appearance of an oil. It is soluble also in alcohol and ether, but is insoluble in alkaline solutions. Hence, it may be separated from morphia by a solution of potassa or soda, which dissolves the morphia, and leaves the codeia. It has an alkaline reaction on test paper, and combines with acids to form salts, some of which are crystallizable, particularly the nitrate. Its capacity of saturation is almost identical with that of morphia. According to Robiquet, 1 part of muriatic acid is saturated by 7·837 of codeia, and by 7·88 of morphia. It is distinguishable, however, from the latter principle, by the different form of its crystals, which are octohedral, by its solubility in boiling ether, greater solubility in water, and insolubility in alkaline solutions, and by not assuming a red colour with nitric acid, nor a blue one with the salts of the sesquioxide of iron. (*Journ. de Pharm.*, xix. 91.) Tincture of galls precipitates from its solutions a tannate of codeia. Crystallized from a watery solution, it contains about six per cent. of water, which is driven off at 212°. The crystals obtained from a solution in ether contain no water. Like most of the other organic alkalies, it consists of nitrogen, carbon, hydrogen and oxygen; its received formula being $NC_{35}H_{20}O_5$, and its combining number consequently 284. According to Dr. Anderson, however, the formula of the anhydrous alkaloid is $NC_{36}H_{21}O_6$, with the addition of two eqs. of water in the hydrate. (*Month. Journ. of Med. Sci.*, May, 1850, p. 492.) Dr. Gregory tried the effects of *nitrate of codeia* upon himself and several of his pupils, and found that, in a dose of three grains or less, it produced no obvious effect, but, in the quantity of from four to six grains, accelerated the pulse, occasioned a sense of heat in the head and face, and gave rise to an agreeable excitement of the spirits like that resulting from intoxicating drinks, which was attended with a sense of itching upon the skin, and, after lasting for several hours, was followed by an unpleasant depression, with nausea and sometimes vomiting. No tendency to sleep was observed, except in the state of depression. In two or three cases the medicine produced a slight purgative effect; but in

* The different effects, obtained by different experimenters from narcotina, are readily explicable, should the statements, contained in previous notes (see *pages* 532 and 533), as to the existence of a powerful alkaloid (opiania), which may have been mixed with the narcotina, and of several different modifications of narcotina itself, prove to be correct.—*Note to the tenth edition.*

others it appeared to exercise no peculiar influence on the bowels. M. Barbier, of Amiens, administered codeia *uncombined* in numerous cases, and observed that, in the dose of one or two grains, it acted on the nervous system, and appeared to be directed especially to the great sympathetic; as it relieved painful affections having their origin apparently in disorders of this nerve, while it exerted no influence over pains of the back and extremities supplied by nerves from the spinal marrow. He did not find it to affect the circulation, to disturb digestion, or to produce constipation. In sufficient quantity, it induced sleep, without occasioning those marks of cerebral congestion occasioned by opium. Dr. Miranda, of Havana, employed it with great advantage in several bad cases of dyspepsia. On the whole, there can be no doubt that this principle has a decided action on the animal economy, and is among those upon which opium depends for its peculiar powers.

Paramorphia (*thebaina*) is the name given by Pelletier to a principle, discovered by him in the precipitate thrown down from an infusion of opium treated with milk of lime. The precipitate being washed with water till the liquid came away colourless, and then treated with alcohol, instead of affording morphia to this solvent, as was anticipated, yielded a new alkaline principle, which was obtained separate by evaporating the alcohol, acting on the residue with ether, allowing the ethereal solution to evaporate spontaneously, and then purifying the resulting crystalline mass by dissolving it in an acid, precipitating by ammonia, and recrystallizing by means of alcohol or ether. Pelletier named it paramorphia, from its close analogy in composition with morphia, from which, however, it is quite distinct in properties. It is white, crystallizable in needles, of an acrid and styptic rather than bitter taste, fusible at about 300°, scarcely soluble in water, very soluble in alcohol and ether even when cold, and still more so when heated, and capable of combining with the acids, with which it forms salts not crystallizable from their aqueous solution. Alkalies precipitate it from its acid solutions, and, unless in very concentrated solution, do not dissolve it when added in excess. It is not, like morphia, reddened by nitric acid, nor does it become blue with solutions of the salts of sesquioxide of iron. From codeia it differs in never being in large crystals, in not forming crystallizable salts, in being always precipitated from its acid solutions by ammonia, and in not melting in oily drops. From narcotina, which it most resembles, it may be distinguished by its shorter crystals, which want the pearly appearance of those of narcotina, by its different taste, by its much greater solubility in cold alcohol, of which 10 parts will dissolve 1 of this principle, while narcotina requires 100 parts, and by the action of nitric acid, which converts it into a resin-like matter before dissolving it, while the same acid instantly dissolves narcotina. It consists of nitrogen, carbon, hydrogen, and oxygen, its formula being $NC_{25}H_{14}O_3$ (*Kane*), and its combining number consequently 202. Dr. Anderson gives the formula $NC_{38}H_{21}O_6$. (See *Journ. de Pharm.*, 3*e sér.*, xxiv. 233.) The name of *thebain* was proposed for it by M. Couërbe, who was disposed to give the credit of its discovery to M. Thiboumery, the director of Pelletier's laboratory. According to Magendie, it is closely analogous, in its effects on the system, to strychnia and brucia, producing tetanic spasms in the dose of a grain. (See *Am. Journ. of Pharm.*, viii. 69.)

Narcein, discovered by Pelletier in 1832, is white, in silky acicular crystals, inodorous, of a slightly bitter taste, fusible at 197° F., soluble in 375 parts of cold and 220 of boiling water, soluble also in alcohol, and insoluble in ether. It forms a bluish compound with iodine, the colour of which is destroyed by heat and the alkalies. It is rendered blue by the action of mineral acids so far diluted as not to decompose it; but does not, like morphia, become blue by the action of the salts of iron, nor red by that of nitric acid. It is dissolved by the acids, but does not neutralize them, and, though at first thought to be alkaline by Pelle-

tier, is not so considered at present. It resembles the organic alkalies, however, in its constitution, consisting of nitrogen, carbon, hydrogen, and oxygen. Its formula is $NC_{28}H_{20}O_{12}$, or, according to Dr. Anderson, $NC_{36}H_{29}O_{18}$. Pelletier obtained it in the course of his analysis of opium. Having formed an aqueous extract of opium, he treated it with distilled water, precipitated the morphia by ammonia, concentrated the solution, filtered it, threw down the meconic acid by baryta water, separated the excess of baryta by carbonate of ammonia, drove off the excess of the ammoniacal salt by heat, evaporated the liquor to the consistence of syrup, set it aside till a pulpy matter formed containing crystals, separated and expressed this pulpy matter, then treated it with alcohol, and concentrated the alcoholic solution. This, upon cooling, deposited crystals of *narceïn*, which were easily purified by repeated solution and crystallization. When mixed with meconin, which often crystallizes with it, the latter may be separated by the agency of ether. It has not been ascertained to have any influence upon the system. Two grains of it have been introduced into the jugular vein of a dog without any observable effect.

Meconin, the existence of which was announced in 1832 by M. Couërbe, is identical with a substance discovered several years previously by M. Dublanc, jun., but of which no account was published. It is perfectly white, in the form of acicular crystals, soluble in about 265 parts of cold and 18 of boiling water, very soluble in ether, alcohol, and the essential oils, fusible at 195°, volatilizable without change, and possessed of a degree of acrimony which favours the supposition that it may not be without action upon the system. It is neither acid nor alkaline, and contains no nitrogen. Meconin is obtained by precipitating the aqueous infusion of opium with ammonia, washing the precipitate with water until the latter nearly ceases to acquire colour, mixing the watery fluids, evaporating them to the consistence of molasses, setting them aside for two or three weeks, during which a mass of granular crystals is formed, then decanting the liquid, expressing the mass, and drying it with a gentle heat. The meconin may be separated from the mass by treating it with boiling alcohol of 36° Baumé, evaporating so as to obtain crystals, dissolving these in boiling water with animal charcoal, filtering the liquid while hot, and subjecting the crystals which form upon the cooling of the solution to the action of ether, which dissolves the meconin, and yields it in a state of purity by spontaneous evaporation. (*Journ. de Pharm.*, Dec. 1832.)

Porphyroxin (*opine*, Berzelius), according to Merck, may be obtained by treating powdered opium (previously exhausted by boiling ether, and then made into a pulp by means of water) with carbonate of potassa, agitating it with ether, evaporating the ethereal solution, dissolving the residue in dilute muriatic acid, and precipitating with ammonia. Paramorphia and porphyroxin are thus obtained together. These are to be dissolved in ether, which, by spontaneous evaporation, deposits the former in crystals, and the latter in the form of resin. The porphyroxin is separated by the cautious use of alcohol, and is obtained by the evaporation of the alcoholic solution. It is neuter, crystallizable in shining needles, insoluble in water, soluble in alcohol and ether, and characterized by the property of assuming a purple-red or rose-colour when heated in dilute muriatic acid. (*Journ. de Pharm.*, 3e *sér.*, xiv. 187.)

Of *pseudomorphia*, as it is found in opium only as an occasional ingredient, and is not generally present, it is scarcely necessary to treat in detail. An interesting fact, however, in relation to it, and one of some toxicological importance, is that it possesses two properties considered characteristic of morphia, those namely of being reddened by nitric acid, and of striking a blue colour with the salts of iron, and yet is without any poisonous influence upon the animal economy. (See *Am. Journ. of Pharm.*, viii. 77, or *Journ. de Pharm.*, xxi. 575.)

But it differs in not forming salts with the acids, and in not decomposing iodic acid. It consists of nitrogen, carbon, hydrogen, and oxygen.

Meconic acid is in white crystalline scales, of a sour taste followed by bitterness, fusible and volatilizable by heat, soluble in four parts of boiling water, soluble also in cold water and alcohol, with the property of reddening vegetable blues, and forming salts. Its compounds with the earths and heavy metallic oxides are generally insoluble in water. Its characteristic properties are, that it produces a blood-red colour with the salts of sesquioxide of iron, a green precipitate with a weak solution of ammoniated sulphate of copper, and white precipitates soluble in nitric acid, with acetate of lead, nitrate of silver, and chloride of barium. It is obtained by macerating opium in water, filtering the infusion, and adding a solution of chloride of calcium. Meconate and sulphate of lime are precipitated. The precipitate, having been washed with hot water and with alcohol, is treated with dilute muriatic acid at 180°. The meconate of lime is taken up, and, upon the cooling of the liquid, bimeconate of lime is deposited. This is dissolved in warm concentrated muriatic acid, which deposits pure meconic acid when it cools. It may be freed from colouring matter by neutralizing it with potassa, decomposing the crystallized meconate thus obtained by muriatic acid, and again crystallizing. Meconic acid has little or no action on the system, and is not used separately in medicine; but its natural relation to morphia requires that it should be understood.

Incompatibles. All the substances which produce precipitates with opium do not necessarily affect its medical virtues; but the *alkalies*, and all vegetable infusions containing tannic and gallic acids, are strictly incompatible; the former separating and precipitating the active principle, the latter forming with it an insoluble compound.

The proportion of morphia which any particular specimen of opium will furnish, may be considered as the best test of its value, except that of actual trial upon the system. Good opium should yield ten or twelve per cent. of the impure morphia precipitated from the infusion by ammonia with alcohol, according to the process of the United States Pharmacopœia. (See *Morphia.*) The Edinburgh College gives the following test. "A solution from 100 grains of fine opium macerated twenty-four hours in two fluidounces of water, filtered, and strongly squeezed in a cloth, if treated with a cold solution of half an ounce of carbonate of soda in two waters, yields a precipitate, which weighs, when dry, at least ten grains, and dissolves entirely in solution of oxalic acid."

M. Guilliermond gives the following mode of estimating the strength of opium, as tested by the amount of morphia which it will yield. Take 15 parts of opium, cut it in pieces, rub it up with 60 parts of alcohol at 160°, drain the mixture on linen and express, treat the residue with 40 parts of alcohol at the same temperature, unite the tinctures in a vessel with a large mouth into which 4 parts of solution of ammonia (22° Cartier) have been introduced, and allow the mixture to stand 12 hours. The crystals which form are to be put upon linen, washed repeatedly with water to separate the meconate of ammonia, and then introduced into a small vessel of water. The crystals of narcotina being very light, remain suspended in the water, and may be decanted along with it, while those of morphia, remaining at the bottom, may be collected and weighed. Good opium treated in this way will yield for the 15 parts employed from 1·25 to 1·75 parts of the crystals of morphia. (*Journ. de Chim. et de Pharm.*, xvi. 18.)*

* As the morphia obtained in the above process is not quite free from narcotina, M. De Vry proposes the following modification. The mixture of morphia and narcotina, precipitated from the alcoholic solution by ammonia, after being washed, is to be heated with a slight excess of sulphate of copper dissolved in pure water. The narcotina has no action on the sulphate of copper, which is decomposed by the morphia, producing sulphate of

Tests of Opium. It is sometimes highly important to be able to ascertain the presence or absence of opium in any suspected mixture. As meconic acid and morphia have been found only in the products of the poppy, if either or both of them be shown to exist in any substance, very strong evidence is afforded of the presence of opium in that substance. Our tests should, therefore, be applied in reference to the detection of these two principles. If an aqueous infusion of the substance examined yield a red colour with the tincture of chloride of iron, there is presumptive evidence of the presence of meconic acid. Greater certainty may be obtained by the following process. Add in excess to the filtered liquor a solution of acetate of lead. If opium be present, there will be a precipitate of meconate of lead, and the acetates of morphia and lead will remain in solution. The precipitate is then to be suspended in water, and decomposed, either by adding a little diluted sulphuric acid, which forms the sulphate of lead and leaves the meconic acid in solution, or by passing through it a stream of sulphuretted hydrogen, removing by filtration the precipitated sulphuret of lead, and heating the clear liquor so as to drive off the sulphuretted hydrogen. With the clear liquor thus obtained, if it contain meconic acid, the tincture of chloride of iron will produce a striking red colour, the ammoniated sulphate of copper a green precipitate, and acetate of lead, nitrate of silver, and chloride of barium, white precipitates soluble in nitric acid. Sulphocyanuret of potassium, which, according to Dr. Wright, is an invariable constituent of saliva (*Simon's Chemistry*, ii. 6), produces a red colour with the salts of sesquioxide of iron, resembling that produced by meconic acid; but, according to Mr. Everitt, this colour is entirely and at once destroyed by a solution of corrosive sublimate, which has no effect on the red colour of the meconate of iron. (See *Am. Journ. of Pharm.*, xii. 88.) On the contrary, chloride of gold reddens a solution of hydrosulphocyanic acid or a sulphocyanuret, but not of meconic acid. Pereira says the acetates also redden the salts of sesquioxide of iron; but they do not afford the results above mentioned with acetate of lead and chloride of barium. To test the presence of morphia, the liquid from which the meconate of lead has been precipitated, and which may be supposed to contain the acetates of morphia and lead, must be freed from the lead by a stream of sulphuretted hydrogen, and then from the sulphuretted hydrogen by heat; after which, the following reagents may be applied:—viz. 1. nitric acid, which colours the morphia red; 2. iodic acid, which is decomposed by the morphia with the extrication of iodine, which colours the liquid reddish-brown, and, if starch is present, unites with it to form a blue compound; 3. solution of ammonia, which, if carefully added so as not to be in excess, throws down a precipitate of morphia soluble in a great excess of that alkali or of potassa; and 4. tannic acid, which precipitates an insoluble tannate of morphia. If the precipitate thrown down by ammonia afford a deep-red colour, becoming yellow, with nitric acid, and a blue colour with the sesquichloride of iron, the proof may be considered as complete.*

morphia and tribasic sulphate of copper. The latter and the narcotina remain undissolved, and a solution is obtained containing sulphate of morphia with a little sulphate of copper. This being filtered is treated first with sulphuretted hydrogen, which precipitates the copper, and afterwards with ammonia which throws down the morphia. (*Pharm. Journ. and Trans.*, x. 77.)

* Merck has proposed a test of opium, founded on the property which characterizes porphyroxin of assuming a red colour when heated in dilute muriatic acid. The suspected liquid is first to be carefully evaporated, a few drops of solution of potassa are to be added, and the mixture agitated with ether. The ethereal solution being filtered off, a slip of unsized paper is to be dipped into it and dried; and the moistening and drying should be repeated several times. The paper thus prepared is to be moistened with dilute muriatic acid, and then exposed to the vapour of boiling water. If it become reddened, opium may be inferred to exist in the liquid tested. M. Heusler states that this test is not applicable

Medical Properties and Uses. Opium is a stimulant narcotic. Taken by a healthy person, in a moderate dose, it increases the force, fulness, and frequency of the pulse, augments the temperature of the skin, invigorates the muscular system, quickens the senses, animates the spirits, and gives new energy to the intellectual faculties. Its operation, while thus extending to all parts of the system, is directed with peculiar force to the brain, the functions of which it excites sometimes even to intoxication or delirium. In a short time this excitation subsides; a calmness of the corporeal actions, and a delightful placidity of mind succeed; and the individual, insensible to painful impressions, forgetting all sources of care and anxiety, submits himself to a current of undefined and unconnected, but pleasing fancies; and is conscious of no other feeling than that of a quiet and vague enjoyment. At the end of half an hour or an hour from the administration of the narcotic, all consciousness is lost in sleep. The soporific effect, after having continued for eight or ten hours, goes off, and is generally succeeded by more or less nausea, headache, tremors, and other symptoms of diminished or irregular nervous action, which soon yield to the recuperative energies of the system; and, unless the dose be frequently repeated, and the powers of nature worn out by over-excitement, no injurious consequences ultimately result. Such is the obvious operation of opium when moderately taken; but other effects, very important in a remedial point of view, are also experienced. All the secretions, with the exception of that from the skin, are either suspended or diminished; the peristaltic motion of the bowels is lessened; pain and inordinate muscular contraction, if present, are allayed; and general nervous irritation is composed, if not entirely relieved.

In doses insufficient to produce the full soporific effect, the stimulant influence upon the mental functions continues longer, and the subsequent calming effect is sustained for hours; sleep being not unfrequently prevented, or rendered so light and dreamy that, upon awaking, the patient will scarcely admit that he has slept at all. When large doses are taken, the period of excitement and exhilaration is shorter; the soporific and anodyne effects are more intense and of longer duration; and the succeeding symptoms of debility are more obvious and alarming.

From quantities sufficient to destroy life, after a brief excitement, the pulse is reduced in frequency though not in force, muscular strength is diminished, and feelings of languor and drowsiness supervene, which soon eventuate in a deep apoplectic sleep. A stertorous respiration; a dark suffusion of the countenance; a full, slow, and labouring pulse; an almost total insensibility to external impressions; and—when a moment of consciousness is obtained by violent agitation, or irritating applications—a confused state of intellect, and an irresistible disposition to sink back into comatose sleep, are symptoms which, for the first few hours, attend the operation of the poison. Though not signs of an elevated condition of the bodily powers, neither do they imply a state of pure, unmixed debility. The pulse is, indeed, slow; but it is often so full and strong as even to call for the use of the lancet. In the space, however, of a few hours, varying according to the quantity of the narcotic taken, and the powers of the patient's constitution, a condition of genuine debility ensues; and this condition will be hastened in point of time, though it will be more under the control of remedies, if the opium be evacuated from the stomach. Called to an individual labouring under the influence of a fatal dose of opium, at a period from six to eight hours after it has been swallowed, the practitioner will generally find him with a cool, clammy skin; cold extremities; a pallid countenance; a feeble, thread-

to the aqueous solution or extract of opium, because porphyroxin is insoluble in water; but Mr. Robertson, of Rotterdam, has found it to succeed with the watery extract, and infers that the porphyroxin is so combined in opium as to render it in some measure soluble. (*Journ. de Pharm.*, 3e *sér.*, xxii. 190.)—*Note to the tenth edition.*

like, scarcely perceptible pulse; a slow, interrupted, almost gasping respiration; and a torpor little short of absolute, death-like insensibility. Death soon follows, unless relief is afforded.

No appearances are revealed by the dissection of those who have died of the immediate effects of opium, which can be considered as affording satisfactory evidence of its mode of operation. The redness occasionally observed in the mucous membrane of the stomach is not constantly present, and is ascribable as much to the irritating effect of remedies prescribed, or to the spirituous vehicle in which the poison has been swallowed, as to the action of the poison itself. Such at least is the inference drawn by Nysten from his experiments and observations; and Orfila states that the stomachs of dogs which he had killed by opium, internally administered, did not present the slightest vestige of inflammation. The force of the medicine is directed to the cerebral and nervous functions; and death is produced by a suspension of respiration, arising from the want of due influence from the brain. The section of the par vagum on both sides has not been found to prevent or retard the death of animals to which large doses of opium have been given, nor even materially to modify its narcotic effects. (*Nysten, quoted by Orfila.*) It would seem, therefore, that the active principle is conveyed into the circulation, and operates upon the brain, and probably upon the nervous system at large, by immediate contact. It is an error to attribute the anodyne, sedative, and soporific effects of the medicine to the previous excitement. They are, as much as this very excitement, the direct results of its action upon the brain. It is in the state of exhaustion and collapse which ensue after the peculiar influence of the opium has ceased, that we are to look for an illustration of that principle of the system, by which any great exaltation of its energies above the natural standard is followed by a corresponding depression. We may be permitted to advance the conjecture, that the excitement which almost immediately supervenes upon the internal use of opium, may be in some degree produced by means of nervous communication; while the succeeding narcotic effects are attributable to its absorption and entrance into the circulation; and the prostration of all the powers of the system which ultimately takes place, is a necessary consequence of the previous agitation of the various organs.

On some individuals opium produces very peculiar effects, totally differing from the ordinary results of its operation. In very small quantities it occasionally gives rise to excessive sickness and vomiting, and even spasm of the stomach; in other cases it produces restlessness, headache, and delirium; and we have known it, even in large doses, to occasion obstinate wakefulness. The headache, want of appetite, tremors, &c., which usually follow, in a slight degree, its narcotic operation, are uniformly experienced by some individuals to such an extent, as to render the use of the medicine very inconvenient. It is possible that some of these disagreeable effects may arise not from the meconate of morphia contained in the opium, but from some other of its ingredients, and those which do result from the meconate may not be produced by other salts of morphia. It has, indeed, been found that the operation of opium may often be favourably modified by changing the state of combination in which its active principle naturally exists. Dissolved in vinegar or lemon juice, it had been known to act in some instances more pleasantly and effectually than in substance, or in the state of tincture, long before physicians had learned to explain the fact by referring it to the production of an acetate or citrate of morphia. When upon the subject of morphia, we shall take occasion to treat of the medical properties of this principle in its various combinations.

An occasional effect of opium, which has not yet been alluded to, is a disagreeable itching or sense of pricking in the skin, which is sometimes attended with a species of miliary eruption. We have found the effect to result equally from all the preparations of this narcotic.

The general operation of opium may be obtained by injecting it into the rectum, or applying it to the surface of the body, especially upon a part denuded of the cuticle. It has appeared to us, when thus applied, to produce less general excitement, in proportion to its other effects, than when administered by the mouth; but we do not make the statement with entire confidence. It is said that, when introduced into the cellular membrane, it acts with great energy; and, when thrown into the cavity of the peritoneum, speedily produces convulsions and death. Injected into the cavity of the heart, it impairs or altogether destroys the powers of that organ.

The local effects of opium are similar in character to those which follow its general operation. An increased action of the part is first observable; then a diminution of its sensibility and contractility; and the latter effect is more speedy, more intense, and of longer continuance, the larger the quantity in which the narcotic is applied.

In all parts of the world, opium is habitually employed by many with a view to its exhilarating and anodyne influence. This is particularly the case among the Mahomedans and Hindoos, who find in this narcotic the most pleasing substitute for those alcoholic drinks which are interdicted by the precepts of their religion. In India, Persia, and Turkey, it is consumed in immense quantities; and many nations of the East smoke opium as those of the West smoke tobacco. This is not the place to speak of the fearful effects of such a practice upon both the intellectual and bodily faculties.

The use of opium as a medicine can be clearly traced back to Diagoras, who was nearly contemporary with Hippocrates; and it was probably employed before his time. It is at present more frequently prescribed than perhaps any other article of the materia medica. Its extensive applicability to the cure of disease will be rendered evident by a view of the indications which it is calculated to fulfil. 1. It is excitant in its primary action. In low or typhoid complaints, requiring a supporting treatment, it exalts the actions of the arterial and nervous systems, and, in moderate doses frequently repeated, may be employed with advantage in conjunction or alternation with other stimulants. 2. It relieves pain more speedily and effectually than any other known medicine, with the exception of ether and chloroform. If possessed of no other property than this, it would be entitled to high consideration. Not to mention cancer, and other incurable affections, in which the alleviation afforded by opium is of incalculable value, we have numerous instances of painful diseases which are not only temporarily relieved, but entirely cured by the remedy; and there is scarcely a complaint in the catalogue of human ailments, in the treatment of which it is not occasionally demanded for the relief of suffering, which, if allowed to continue, might aggravate the disorder, and protract if not prevent a cure. 3. Another very important indication, which, beyond any other narcotic, it is capable of fulfilling, is the production of sleep. For this purpose it is given in a great variety of diseases; whenever, in fact, morbid vigilance exists, not dependent on acute inflammation of the brain. Among the complaints in which it proves most serviceable in this way is delirium tremens, or the mania of drunkards, in which it is frequently sufficient of itself to effect a cure. Opium produces sleep in two ways; first, by its direct operation on the brain, secondly, by allaying that morbid nervous irritation upon which wakefulness generally depends. In the latter case it may frequently be advantageously combined with camphor or Hoffmann's anodyne. 4. Opium is powerfully antispasmodic. No medicine is so efficient in relaxing spasm, and in controlling those irregular muscular movements which depend on unhealthy nervous action. Hence its great importance as a remedy in tetanus; colic; spasm of the stomach attending gout, dyspepsia, and cholera; spasm of the ureters in nephritis, and of the biliary ducts during

the passage of calculi; and in various convulsive affections. 5. Probably dependent upon a similar influence over the nervous system, is the property which it possesses of allaying general and local irritations, whether exhibited in the nerves or bloodvessels, provided the action do not amount to positive inflammation; and even in this case it is often prescribed with advantage. Hence its use in composing restlessness, quieting cough, and relieving nausea, tenesmus, and strangury. 6. In suppressing morbid discharges, it answers another indication which fits it for the treatment of a long list of diseases. This effect it is, perhaps, enabled to produce by diminishing the nervous energy upon which secretion and muscular motion depend. Upon this principle it is useful in diarrhœa, when the complaint consists merely in increased secretion into the bowels, without high action or organic derangement; in consumption, chronic catarrh, humoral asthma, and other cases of morbidly increased expectoration; in diabetes, and in certain forms of hemorrhage, particularly that from the uterus, in combination with other remedies. 7. It remains to mention one other indication; that, namely, of producing perspiration, in fulfilling which, opium, conjoined with small doses of emetic medicines, is pre-eminent. No diaphoretic is so powerful as a combination of opium and ipecacuanha; and none is so extensively employed. We shall speak more fully of this application of the remedy under the head of *Pulvis Ipecacuanhæ et Opii*. It is here sufficient to say, that its beneficial effects are especially experienced in rheumatism, the bowel affections, and certain pectoral diseases.

From this great diversity of properties, and the frequent occurrence of those morbid conditions in which opium affords relief, it is often prescribed in the same disease to meet numerous indications. Thus, in idiopathic fevers, we frequently meet with morbid vigilance and great nervous irritation, combined with a low condition of the system. In typhous pneumonia, there is the same depression of the vital powers, combined often with severe neuralgic pains, and much nervous irritation. In diarrhœa, besides the indications presented by the spasmodic pain and increased discharge, there is a strong call for the diaphoretic operation of the opium. It is unnecessary to multiply instances. There is hardly a complaint which does not occasionally present a complication of symptoms demanding the use of this remedy.

But a medicine possessed of such extensive powers may do much injury, if improperly directed; and conditions of the system frequently occur, in which, though some one of the symptoms calls for its use, others, on the contrary, are incompatible with it. Thus, opium is contra-indicated by a high state of inflammatory excitement, which should be reduced before we can with propriety venture upon its employment; and when there is any doubt as to the sufficiency of the reduction, the opium should be given in combination with tartarized antimony or ipecacuanha, which modify its stimulant operation, and give it a more decided tendency to the skin. It is also contra-indicated by inflammation of the brain, or strong determination of blood to the head, by deficient secretion from inflamed mucous membranes, as in the early stages of bronchitis, and generally by constipation of the bowels. When, however, the constipation depends upon intestinal spasm, as in colic, it is sometimes relieved by the antispasmodic action of the opium; and the binding effects of the medicine may generally be counteracted by the use of laxatives.

Opium is usually administered in substance or in tincture. In the former state it is given in the shape of pill, which, as a general rule, should be formed out of powdered opium, as it is thus more readily dissolved in the liquors of the stomach, and therefore operates more speedily and effectually than when made, as it sometimes is, immediately from the plastic mass. There is no medicine of which the dose is more variable, according to the habits of the patient, the nature of his complaint, or the purpose to be effected. While in catarrh and diarrhœa we often prescribe not more than one-fourth or one-third of a grain, in tetanus

and some other nervous affections, it has been administered, without abating the violence of the symptoms, in the enormous quantity of two drachms in twenty-four hours; and in a case of cancer of the uterus, under the care of the late Drs. Monges and La Roche, of this city, the quantity is stated to have been gradually increased till the amount taken during one day, either in the shape of tincture or in substance, was equivalent to more than three ounces. The medium dose, in ordinary cases of disease, to produce the anodyne and soporific effects of the medicine, is one grain.

Experience has shown that the action of opium is sometimes favourably modified by employing only those of its constituents which are soluble in water. Hence the watery extract is sometimes advantageously substituted for the drug itself, and an infusion for the tincture.* (See *Extractum Opii.*)

Opium may often be administered with great advantage by the rectum. In this way it operates most advantageously in cases of obstinate vomiting, of painful nephritic and uterine affections, of strangury from blisters, and of dysenteric tenesmus. It may be employed as a suppository, or in the form of enema made with laudanum and a small quantity of viscid liquid, as flaxseed tea, mucilage of gum Arabic, or starch prepared with hot water. The quantity, as a general rule, may be three times that administered by the mouth; but the relative susceptibility of the stomach and rectum in different persons is not always the same; and the effects produced by the narcotic, given by injection, are sometimes much greater than was anticipated. The practitioner, moreover, should take into consideration the previous habits of the patient. In an individual who has long been accustomed to take opium internally, and whose stomach will receive large doses with impunity, it is possible that the rectum may not have lost, in a proportionate degree, its absorbing power or susceptibility; and that serious consequences might result by adhering, in such a case, to the general rule as to the relative quantity to be given in the way of enema or suppository.

In some one of its liquid preparations, opium is often used externally as an addition to collyria in ophthalmia, to injections in gonorrhœa, and to lotions and cataplasms in various complaints of the skin, and external pains, as those of gout and rheumatism. It is also employed in substance as a local anodyne, in the form of a plaster or cataplasm made from the powder. But its external use requires some caution, especially when the skin is deprived of the cuticle. Death is said to have resulted from a cataplasm, containing a large quantity of laudanum, applied to the epigastrium. (*Ann. de Thérap.*, 1843, p. 5.)

When opium has been taken in an overdose, the only effectual mode of relief is immediately to evacuate the stomach, either by means of the stomach-pump, or, when this is not attainable, by the more active emetics, such as tartarized antimony, sulphate of zinc, or sulphate of copper, conjoined with ipecacuanha. Emetics are preferable to the stomach-pump, when opium has been swallowed in substance; as the capacity of the tube is insufficient to admit of the passage of the masses in which the poison is sometimes taken. The operation of the emetic should be promoted by a very free use of warm drinks, by irritating the fauces with a feather, by keeping the patient in motion, and, if the insusceptibility to the action of the remedy is very great, by dashing cold water upon the

* A good extemporaneous infusion of opium cannot well be prepared. Hence, to obtain the effects of this preparation it is best to dissolve the extract in water. Mr. Eugene Dupuy, of New York, first prepares an infusion, and then adds alcohol enough to preserve it; so that the preparation may be kept ready made by the apothecary, to be used as a substitute for laudanum. He takes ten drachms of opium, reduces it to a thin pulp with water, allows the mixture to stand 48 hours, then percolates with water so as to obtain twelve fluidounces of infusion, to which four fluidounces of alcohol of 95 per cent. are added. The preparation is intended to be of about the same strength as laudanum. Consequently the dose should be from twelve to fifteen minims, or about as many drops. (*Am. Journ. of Pharm.*, xxiii. 211.)

head and shoulders, thus counteracting, for a moment, the narcotic influence of the opium upon the brain, and enabling this organ to receive and transmit the necessary impressions. Advantage will sometimes accrue from a moderate loss of blood, which tends to diminish the cerebral congestion, and thus not only awaken susceptibility to the impression of the emetic, but obviate also the danger of hemorrhagic effusion; but the bleeding should not be carried far, in consequence of danger from the subsequent debility. For the same purpose of favouring the emetic action, it has been recommended to pass a current of electricity through the brain. After the evacuation of the poison, the chief indication is to obviate the debility which generally supervenes, and which, when the quantity of the narcotic has been large, or has remained long in the stomach, is sometimes alarming and even fatal. For this purpose the carbonate of ammonia, or the aromatic spirit of ammonia, with wine whey, may be employed internally, and sinapisms and stimulant frictions applied to the surface. The practitioner should not despair even if called at the last moment. The stomach tube may be applied at any period; and it is possible that, even without evacuation of the stomach, a little aid may enable the system to resist the prostrating influence of the poison, if not taken in an overwhelming dose. The electro-magnetic battery was employed with great advantage in a case of prostration of this kind by Dr. Page, of Valparaiso; and the practice has been imitated in Europe and this country. Strong coffee, under these circumstances, has been found useful, and is obviously suggested in all cases by its powerful influence in producing wakefulness. Should other measures fail, resort may be had to artificial respiration, by which the functions of the lungs and heart may possibly be sustained till the brain has struggled through its conflict with the narcotic, and is enabled to resume its healthful action. Brodie has demonstrated that death from many of the narcotics results from a suspension of the cerebral influence necessary to sustain the respiratory function, and that the heart ceases to act in consequence of the cessation of respiration. If this can be restored artificially before the contractions of the heart have entirely ceased, the circulation may continue, and life be supported for a time without aid from the brain, which now receives a supply of arterial blood, and is thus better enabled to rise above the repressing action of the opium. As this narcotic does not produce a structural derangement, but operates chiefly upon the nervous power, a favourable result is more likely to be experienced than in cases of poisoning from some other articles of the same class. Several cases are on record, in which patients, apparently in the very last stage, were saved by a resort to artificial respiration. (See *N. Am. Med. and Surg. Journ.*, iii. 277, and *Am. Journ. of the Med. Sci.*, xx. 450.)

ORIGANUM. *U. S., Ed.*

Origanum.

The herb of Origanum vulgare. *U. S., Ed.*

Origan, *Fr.;* Gemeiner Dosten, Wohlgemuth, *Germ.;* Origano, *Ital.;* Oregano, *Span.*

ORIGANUM. *Sex. Syst.* Didynamia Gymnospermia.—*Nat. Ord.* Lamiaceæ or Labiatæ.

Gen. Ch. Strobile four-cornered, spiked, collecting the calyces. *Corolla* with the upper lip erect and flat, the lower three-parted, with the segments equal. *Willd.*

Two species of Origanum have been used in medicine, *O. Majorana* or sweet marjoram, and *O. vulgare* or common marjoram. The former, however, having been discarded from the Dublin Pharmacopœia, which was the last to retain it, is no longer officinal. It grows wild in Portugal and Andalusia, and is cultivated as a garden herb in other parts of Europe, and in the United States. Some authors, however, consider *O. Majoranoïdes*, which is a native of Barbary, and closely allied to *O. Majorana*, as the type of the sweet marjoram of our gardens. *Sweet marjoram* has a pleasant odour, and a warm, aromatic, bitterish taste, which it imparts to water and alcohol. By distillation with water it yields a volatile oil, which is directed by the Edinburgh College among their preparations, probably by mistake, as the plant has been rejected. It is tonic and gently excitant, but is used more as a condiment in cookery than as a medicine. In domestic practice, its infusion is much employed by the vulgar to hasten the tardy eruption in measles and other exanthematous diseases.

Origianum vulgare. Willd. *Sp. Plant.* iii. 135; Woodv. *Med. Bot.* p. 344, t. 123. Origanum or *common marjoram* is a perennial herb, with erect, purplish, downy, four-sided, trichotomous stems, which rise about eighteen inches high, and bear opposite, ovate, entire, somewhat hairy leaves, of a deep yellowish-green colour. The flowers are numerous, of a pinkish-purple or rose colour, disposed in roundish, panicled spikes, and accompanied with ovate reddish bractes, longer than the calyx. This is tubular and five-toothed, with nearly equal segments. The corolla is funnel-shaped, with the upper lip erect, bifid, and obtuse, the lower trifid, blunt, and spreading. The anthers are double, the stigma bifid, and reflexed.

The plant is a native of Europe and America. In this country it grows along the road sides, and in dry stony fields and woods, from Pennsylvania to Virginia, and is in flower from June to October; but it is not very abundant, and is seldom collected for use. It has a peculiar, agreeable, aromatic odour, and a warm, pungent taste. These properties it owes to a volatile oil, which is the part chiefly employed. It may be separated by distillation; but is mostly imported from Europe. (See *Oleum Origani.*)

Medical Properties and Uses. Origanum is gently tonic and excitant, and has been used in the form of infusion as a diaphoretic and emmenagogue, and externally as a fomentation; but it is at present scarcely employed.

OS. *U. S.*

Bone.

Off. Syn. OSSA. Bones of the ox, or Bos Taurus. *Dub.*
Os, *Fr.;* Knochen, *Germ.;* Ossa, *Ital.;* Huesos, *Span.*

Bones are employed in several pharmaceutical processes, and those derived from the domestic quadrupeds, especially the ox, are the kind intended for officinal use. They have been expunged from the officinal list of the Edinburgh College, though used by the College for preparing phosphate of soda.

Properties, &c. They are solid, white, and of a lamellated texture, and constitute the skeleton of the superior orders of animals, of which they are the hardest and densest parts. They consist of a cellular gelatinous tissue, the cavities of which are filled up with certain earthy salts, to be mentioned presently. When subjected to destructive distillation, in *close* vessels, they are decomposed

without alteration of shape, lose about three-sevenths of their weight, become brittle, and are converted into a black carbonaceous substance, containing the earthy salts of the bone, and constituting the species of animal charcoal called *bone-black*. (See *Carbo Animalis*.) The portions which distil over consist of the usual ammoniacal products derived from animal matter. (See *Ammoniæ Murias*.) When calcined in *open* vessels they lose more of their weight in consequence of the dissipation of the charcoal, and are converted into a white friable substance, consisting of the incombustible part, and commonly called *bone-earth*, or *bone-ash*; and a similar residue is obtained by calcining horn. (See *Cornu Ustum*.) Treated with boiling water, a small portion of the gelatinous matter is dissolved; but, when acted on by water in a *Papin's digester*, the whole of it is taken up, and the earthy salts, deprived of their cement, crumble into powder, and become diffused through the solution. When subjected to the action of dilute muriatic acid, the earthy salts are dissolved, and the bone softens without losing its shape, and becomes semitransparent and flexible. The portion remaining unattacked by the acid is the gelatinous tissue, which may be converted into gelatin by long boiling. This portion of bone is nutritious, and has been prepared so as to form a wholesome aliment by M. d'Arcet. His process for obtaining it consists in digesting bones in weak muriatic acid for seven or eight days, occasionally renewing the acid, plunging them for a few moments in boiling water, and then subjecting them to a strong current of cold water. The pure animal matter, thus procured, is made into cakes, called *portable soup* (*tablettes de bouillon*), by dissolving it in water, concentrating the solution until it gelatinizes, and drying the matter obtained.

Composition. The bones of different animals, and of the same animal at different ages, vary somewhat in their composition. Dry ox-bones, according to Berzelius, consist of bone-gelatin (cartilage of bone) 33·3, bone-phosphate of lime with a little fluoride of calcium 57·35, carbonate of lime 3·85, phosphate of magnesia 2·05, soda with a very little chloride of sodium 3·45=100. Fourcroy and Vauquelin's results give a larger proportion of animal matter and carbonate of lime, and a smaller of bone-phosphate. Fossil bones have the same general composition. Human bones differ somewhat in the proportions of their constituents, and in containing traces of iron and manganese. According to Dr. W. Heintz, however, bones exhausted with water, so as to remove the colouring matter of blood, contain not a trace of iron. Marchand found one per cent. of fluoride of calcium in human bone. *Bone-phosphate of lime* consists, according to Mitscherlich, of one eq. of acid and three of lime. This analysis makes it a tribasic phosphate, and the same composition has been assigned to it by Dr. Heintz. (*Chem. Gaz.*, June 15, 1849.)

Uses. Bones are applied to numerous uses. Burnt to whiteness, they furnish bone-phosphate of lime, from which phosphorus and all its compounds are either directly or indirectly obtained. (See *Phosphorus*.) Subjected to destructive distillation in close vessels, they yield *impure carbonate of ammonia* and empyreumatic oil; and a carbonaceous residue is left, called *bone-black*. Calcined, pulverized, and washed, they form the material of which *cupels* are made. As bone-dust, they form an excellent manure. Deprived of their earthy salts by weak acids, they furnish a nutritious article of diet. By proper treatment with water they furnish gelatin, applicable not only to the purposes of size and common glue, but also to those of the finer sorts of gelatin, called isinglass, in making animal jellies, and for the fining of wines. (See *Ichthyocolla* and *Cornu*.) The hoof bones of the ox, when boiled with water, furnish a peculiar oil, called neats-foot oil. (See *Oleum Bubulum*.)

OVUM. *U. S., Ed., Dub.*

Egg.

The egg of Phasianus Gallus. *U. S., Ed., Dub.*

Off. Syn. OVI ALBUMEN. Gallus Bankiva, *var. domesticus.* The white of the egg. OVI VITELLUS. The yolk of the egg. *Lond.*

Œuf, *Fr.;* Ei, *Germ.;* Ovo, *Ital.;* Huevo, *Span.*

The common dunghill fowl is supposed to have come originally from India, where it is found in a wild state. It is now domesticated in almost all parts of the globe.

The egg, which is the only officinal product, consists of 1. an exterior covering called the shell; 2. a white, semi-opaque membrane, lining the internal surface of the shell; 3. the white; 4. the yolk. Other distinct parts are recognised by the comparative anatomist, but they have no peculiar interest for the practical physician or pharmaceutist.

1. The shell—*testa ovi* or *putamen ovi*—consists, according to Vauquelin, chiefly of carbonate of lime, with animal matter, and a minute proportion of phosphate of lime, carbonate of magnesia, oxide of iron, and sulphur. When exposed to a high degree of heat in the open air, the carbonic acid is driven off, the animal matter consumed, and lime is left nearly pure.

2. The membrane lining the shell appears to be of an albuminous nature.

3. The white—*albumen ovi*—is a glairy viscid liquid contained in very delicate membranes, without odour or taste, readily soluble in water, coagulable by the stronger acids, by alcohol, and by a heat of 160° F. Exposed in thin layers to a current of air, it becomes solid, retaining its transparency and solubility in water. By coagulation it is rendered sapid, white, opaque, and insoluble. At a temperature of 212°, one part of it renders one thousand parts of water in which it has been dissolved opaque. It contains, according to Dr. Bostock, in one hundred parts, 85 of water, 12 of pure albumen, 2·7 of mucus or uncoagulable matter, and 0·3 of saline substances, including soda with traces of sulphur. The white of egg is precipitated by chloride of tin, chloride of gold, subacetate of lead, sulphate of copper, corrosive sublimate, and tannin. When kept in the fluid state it soon putrefies; but, if carefully dried without coagulation, it may be long preserved without change, and may be applied in a state of solution to the same purposes as in its original condition.

4. The yolk—*vitellus ovi*—is inodorous, of a bland oily taste, and forms an opaque emulsion when agitated with water. By heat it is coagulated into a granular solid, which yields a fixed oil by expression. According to M. Gobley, 100 parts of it contain 51·486 of water, 15·760 of a peculiar albuminous principle denominated *vitellin*, 21·304 of margarin and olein, 0·438 of cholesterin, 7·226 of oleic and margaric acids, 1·200 of phosphoglyceric acid, 0·034 of muriate of ammonia, 0·277 of chlorides of sodium and potassium and sulphate of potassa, 1·022 of phosphates of lime and magnesia, 0·400 of animal extract (*extraite de viande*), and 0·553 of colouring matter, traces of iron, traces of lactic acid, &c. (*Journ. de Pharm.*, 3e *sér.*, xii. 12.)

Medical Properties and Uses. Eggs are applied to various purposes in medicine and pharmacy. The shells, powdered and levigated, may be used beneficially as an antacid in diarrhœa. In common with oyster-shells, they possess the advantage of uniting intimately animal matter with carbonate of lime, the particles of which are thus more thoroughly isolated, and prove more acceptable to the stomach than chalk, in the finest state of division to which the latter can be brought by mechanical means. The dose and mode of preparation are the same with those of oyster-shell. (See *Testa.*)

The *white* of the egg is used chiefly for the clarification of liquids, which it effects by involving, during its coagulation, the undissolved particles, and rising with them to the surface or subsiding. It is highly recommended as an antidote for corrosive sublimate and sulphate of copper, with which it forms insoluble and comparatively inert compounds. It is sometimes also used for the suspension of insoluble substances in water, but is inferior for this purpose to the yolk, and even to mucilage of gum Arabic. Agitated briskly with a lump of alum it coagulates, at the same time dissolving a portion of the alum, and thus forming an astringent poultice, which may be advantageously applied between folds of gauze over the eye, in some states of ophthalmia.

The *yolk* in its raw state is thought to be laxative, and is a popular remedy in jaundice. If beneficial in this complaint, it is probably in consequence of affording a mild nutritious diet, acceptable to the stomach and easily digested. In dyspepsia it is, from this cause, highly useful. The late Dr. Jos. Parrish, of Philadelphia, found great advantage in that complaint from the habitual use of the yolk of egg, beat up with water and a little ginger. In pharmacy, the yolk is highly useful as an intermedium between water and insoluble substances, such as the balsams, turpentine, oils, &c. It is a mistake to employ the white, instead of the yolk of eggs, in preparing emulsions.

PANAX. *U.S. Secondary.*

Ginseng.

The root of Panax quinquefolium. *U. S.*

Ginseng, *Fr., Germ., Span.;* Ginsen, *Ital.*

Panax. *Sex. Syst.* Pentandria Digynia. (Polygamia Dicœcia, *Linn.*)—*Nat. Ord.* Araliaceæ.

Gen. Ch. Flowers polygamous. *Umbel* simple. *Calyx* five-toothed. *Corolla* of five petals. *Berry* inferior, subcordate, two, sometimes three-seeded. *Calyx* in the male flower entire. *Nuttall.*

Panax quinquefolium. Willd. *Sp. Plant.* iv. 1124; Woodv. *Med. Bot.* p. 149, t. 58; Bigelow, *Am. Med. Bot.* ii. 82. The ginseng has a perennial root, which sends up annually a smooth round stem, about a foot high, and divided at the summit into three leafstalks, each of which supports a compound leaf, consisting of five, or more rarely of three or seven petiolate, oblong-obovate, acuminate, serrate leaflets. The flowers are small, greenish, and arranged in a simple umbel, supported by a peduncle, which rises from the top of the stem in the centre of the petioles. The fruit consists of kidney-shaped, scarlet berries, crowned with the styles and calyx, and containing two and sometimes three seeds.

The plant is indigenous, growing in the hilly regions of the Northern, Middle, and Western States, and preferring the shelter of thick, shady woods. The root is the part employed. This is collected in considerable quantities in Ohio and Western Virginia, and brought to Philadelphia and other cities on the sea-board for the purpose of exportation to China, where it is highly valued. Some suppose the ginseng plant of Chinese Tartary to be the same as ours; others believe it to be the *Panax Schinseng* of Nees Von Esenbeck; while by others, again, though acknowledged to be a Panax, it is thought to be a different species from either of those mentioned. While supplied with this drug exclusively from their own native sources, which furnished the root only in small quantities, the Chinese entertained the most extravagant notions of its virtues, considering it as a remedy for all diseases, and as possessing almost miraculous powers in preserving health, invigorating the system, and prolonging life. It is said to have been

worth its weight in gold at Pekin; and the first shipments made from North America to Canton yielded enormous profits. But the subsequent abundance of supply has greatly diminished its value.

The root is fleshy, somewhat spindle-shaped, from one to three inches long, about as thick as the little finger, and terminated by several slender fibres. Frequently there are two portions, sometimes three or more, connected at their upper extremity, and bearing a supposed, though very remote resemblance to the human figure, from which circumstance it is said that the Chinese name *ginseng* originated. When dried, the root is yellowish-white and wrinkled externally, and within consists usually of a hard central portion, surrounded by a soft whitish bark. It has a feeble odour, and a sweet, slightly aromatic taste, somewhat analogous to that of liquorice root. It has not been accurately analyzed, but is said to be rich in gum and starch. It is sometimes submitted, before being dried, to a process of clarification, which renders it semitransparent and horny, and enhances its value as an article of export. The extraordinary medical virtues formerly ascribed to ginseng had no other existence than in the imaginations of the Chinese. It is little more than a demulcent, and in this country is not employed as a medicine. Some persons, however, are in the habit of chewing it, having acquired a relish for its taste; and it is chiefly to supply the wants of these that it is kept in the shops. W.

PAPAVER. *U. S., Lond., Ed., Dub.*

Poppy-heads.

The ripe capsules of Papaver somniferum. *U. S.* The ripe fruit. *Lond.* Capsules not quite ripe. *Ed.* The dried capsules. *Dub.*

Capsules des pavots, *Fr.;* Kapseln des weissen Mohns, *Germ.;* Capidel papavero, *Ital.;* Cabezas de amapola, *Span.*

See OPIUM.

In England the poppy is cultivated chiefly for its capsules, which are gathered as they ripen, and taken to market enclosed in bags. The Edinburgh College directs them to be collected before they are quite ripe, as they then contain more of the active milky juice; but, cut at this period, they are apt to lose their juice through the wounded surface, unless carefully kept inverted upon their crown when drying; and, even when thus treated, they are, according to the observations of Buchner, less active than the capsules collected after perfect maturity, while they contain more of useless saccharine and mucilaginous matter. (*Buchner's Repert.*, 3 R., viii. 289 and 326.) M. Meurein states, as the result of his experiments, that the richest are those collected just before the maturity of the seeds, when the capsules have passed from their glaucous-green to a yellowish-green colour. (*Journ. de Pharm.*, 3e *sér.*, xxiii. 341.) They are occasionally imported into this country; but as no effect is produced by them which cannot be as readily obtained from opium, or some one of its preparations, they are little employed.

The dried poppy capsules vary in size from the dimensions of a small egg to those of the fist. They differ also in shape according to the variety of the poppy

from which they are procured. On the continent two sub-varieties of the white poppy are recognised, the *long*, and the *round or depressed*. Of these, according to Aubergier, the long are richest in morphia, and his conclusions are confirmed by Meurein, who has also found the largest capsules most efficient. Those commonly found in our shops are of a spheroidal shape, flattened below, and surmounted by a crown-like expansion—the persistent stigma—which is marked by numerous diverging rays that rise somewhat above its upper surface, and appear to be prolongations of partial septa, or partitions, proceeding along the interior circumference of the capsule from the top to the bottom. In the recent state, the seeds, which are very numerous, adhere to these septa; but in the dried capsule they are loose in its cavity. The capsules of the black poppy are smaller and more globular than those of the white, and contain dark instead of light-coloured seeds. There appears to be no essential difference in their properties. Both kinds, when fresh, are glaucous, but when dry, as directed in the Pharmacopœias, are of a dirty white or purplish-brown colour, have a consistence somewhat like that of paper, are without smell, and have little taste, unless long chewed, when they are decidedly bitter. Submitted to analysis, they are found to contain principles similar to those of opium, which they yield to water by decoction. They have been employed in France for obtaining morphia.

Medical Properties and Uses. Dried poppy-heads, though analogous to opium in medical properties, are exceedingly feeble. They are sometimes employed in the form of decoction, as an external emollient and anodyne application; and, in the shape of emulsion, syrup, or extract, are often used internally by European practitioners to calm irritation, promote rest, and produce generally the narcotic effects of opium.

W.

PAREIRA. *U. S. Secondary, Lond., Ed., Dub.*

Pareira Brava.

The root of Cissampelos Pareira. *U. S., Lond., Ed., Dub.*

Cissampelos. *Sex. Syst.* Diœcia Monadelphia.—*Nat. Ord.* Menispermaceæ. *Gen. Ch.* Male. *Calyx* four-leaved. *Corolla* none. *Nectary* rotate. *Stamens* four, with connate filaments. Female. *Calyx* one-leaved, ligulate roundish. *Corolla* none. *Styles* three. *Berry* one-seeded.

Cissampelos Pareira. Willd. *Sp. Plant.* iv. 861; Woodv. *Med. Bot.* 3d ed. p. 167, t. 65. This is a climbing plant, with numerous slender, shrubby stems, and roundish, entire leaves, indented at the top, covered with soft hair upon their under surface, and supported upon downy footstalks, which are inserted into the back of the leaf. The flowers are very small, and disposed in racemes, of which those in the female plant are longer than the leaves. The plant is a native of the West Indies and South America, and is supposed to be the source of the root brought from Brazil, under the name of *pareira brava*. According to Auguste St. Hilaire, however, the true pareira is obtained from another species of the same genus, growing in Brazil, and denominated *C. glaberrima;* while by Aublet it is referred to a species of *Abuta*, belonging to the same natural family.

The root comes in pieces from the thickness of the finger to that of the arm, from a few inches to two or more feet in length, cylindrical, sometimes contorted or forked, and covered with a thin, firmly adhering, grayish-brown bark. The outer surface is marked with longitudinal and annular wrinkles, and sometimes, in the larger pieces, with knotty excrescences. The interior is ligneous, yellowish, very porous, marked by irregular concentric circles, inodorous, and of a sweetish, nauseous, bitter taste. The root imparts its virtues readily to water. M. Feneulle found in it a soft resin, a yellow bitter principle, a brown substance,

an azotized substance, fecula, acidulous malate of lime, nitrate of potassa, and various other salts. He considers the yellow bitter substance as the active principle. It is soluble in water and alcohol, and precipitated from its solution by tincture of galls. Wiggers announced, in 1838, the existence in pareira brava of an organic alkali, for which he proposed the name of *cissampelina*. He procured it by boiling the root with water acidulated with sulphuric acid, precipitating by carbonate of potassa, dissolving the precipitate again in water acidulated with sulphuric acid, treating the solution with animal charcoal, precipitating anew with carbonate of potassa, drying and pulverizing the precipitate, treating it repeatedly with ether, and evaporating the ethereal solution. The alkali thus obtained may be rendered entirely pure by dissolving it in diluted acetic acid, precipitating with carbonate of potassa, and washing and drying the precipitate. (*Annal. der Pharm.*, xxvii. 29.) Wiggers did not describe this alkali. It is probably the chief ingredient of the bitter substance obtained by Feneulle. Peretti of Rome and Pelletier afterwards separated an alkali from the root, which was characterized by assuming a beautiful purple colour by contact with strong nitric acid. (*Journ. de Pharm.*, xxvi. 162.) In Christison's Dispensatory it is stated to be uncrystallizable, insoluble in water, soluble in ether, alcohol, and the acids, and of an intensely bitter and sweetish taste.

Medical Properties and Uses. Pareira brava is said to be tonic, aperient, and diuretic. It was introduced into European practice so long ago as 1688, and at one time enjoyed considerable reputation as a lithontriptic. It has been recommended in calculous affections, chronic inflammation and ulceration of the kidneys and bladder, leucorrhœa, dropsy, rheumatism, and jaundice. The purpose for which it is at present chiefly employed is the relief of chronic diseases of the urinary passages. Sir Benjamin Brodie found it very useful in chronic inflammation of the bladder, in allaying irritability of that organ, and correcting the disposition to profuse mucous secretion; and it has subsequently come into general use in the same affections. Advantage may often be derived from combining it, in this complaint, with one of the narcotics, as opium or hyoscyamus. In Brazil, it is used in the cure of the bites of poisonous serpents; a vinous infusion of the root being taken internally, while the bruised leaves of the plant are applied to the wound. The dose of pareira brava in substance is from thirty grains to a drachm. The infusion, however, is more convenient. (See *Infusum Pareiræ*.) A tincture, made by macerating one part of the root in five parts of alcohol, has been given in the dose of a fluidrachm. The aqueous extract may be given in the dose of from ten to thirty grains.

PETROLEUM. *Lond., Ed.*

Petroleum.

A blackish liquid bitumen, flowing spontaneously from the earth. *Lond.*

Barbadoes tar, Rock oil; Pétrole, Huile de Gabian, *Fr.;* Steinöl, *Germ.;* Petrolio, *Ital.;* Petroleo, *Span.*

Petroleum belongs to the class of native inflammable substances, called *bitumens*. These are liquids or readily fusible solids, which emit, when heated, a peculiar smell, burn easily, and leave a very small carbonaceous residue. They are of two kinds, one liquid, called naphtha, the other solid, denominated asphaltum. *Naphtha* is a transparent, yellowish-white, very light and inflammable, limpid liquid, which is found abundantly in Persia. It has been used with asserted advantage in Asiatic cholera, particularly by Dr. Andreosky, of the Russian army. The dose is from ten to twenty drops, given in half a glass of white wine, or in mint-water. It consists exclusively of carbon and hydrogen.

As oxygen does not enter into its composition, it may be advantageously employed for preserving potassium. From the tar formed in the manufacture of coal gas, an *artificial naphtha* is obtained, which by rectification is rendered equally light and limpid with the natural substance. Thus purified, it was found by Mr. James Syme, of Edinburgh, to possess the property of dissolving caoutchouc; and the solution has been usefully applied to the purpose of forming various surgical instruments of that material. This solution has also been employed, at the suggestion of Mr. Mackintosh, of Glasgow, for rendering cloth and other fabrics water-proof. They are varnished with the solution on one side, and the varnished surfaces are applied to each other, and made to adhere by powerful pressure. *Asphaltum* is solid, black, dry, friable, and insoluble in alcohol. These two varieties of bitumen often exist in a state of mixture in nature. When the asphaltum predominates it takes the name of *maltha* or *mineral tar;* when the naphtha is in the larger proportion it is called *petroleum.*

Localities. Petroleum is found principally at Amiano in Italy, at Gabian in France, upon the borders of the Caspian Sea, near Rangoon in the Birman Empire, and in Barbadoes, Trinidad, and other West India Islands. An interesting account of the pitch lake of Trinidad, by Mr. Darling, is contained in the ninth volume of the *Pharm. Journal and Transactions.* The wells of petroleum in Birmah are said to produce four hundred thousand hogsheads annually.

In the United States, petroleum is found in various localities, the principal of which are on the Kenhawa in Virginia; near Scottsville in Kentucky; in Western Pennsylvania; on Duck Creek in Ohio; and on the shores of Seneca Lake in New York. That found in the latter locality is usually called in this country Seneca oil; and similar varieties of petroleum from other domestic sources are known by the same name.

Barbadoes petroleum is a black, nearly opaque, inflammable liquid, of the consistence of molasses, unctuous to the touch, and possessing a bituminous taste, and strong and tenacious odour. Its sp. gr. varies from 0·730 to 0·878. When subjected to distillation, it yields naphtha, and leaves a solid residue of asphaltum. It is little affected by alcohol, acids, or alkalies, but dissolves in ether and in the fixed and volatile oils. It consists chiefly of carbon and hydrogen, associated with a little nitrogen and oxygen. *Rangoon petroleum* has a reddish-black colour, a strong, rather fragrant odour, and the consistence of lard in summer. When heated to 90°, it becomes a reddish-brown very mobile liquid. Dr. Christison obtained from it by distillation, first, a large quantity of naphtha, and afterwards a crystalline principle, which he ascertained to be identical with paraffin. In the naphtha Dr. Gregory subsequently discovered eupione. It is probable, as Dr. Christison remarks, that this petroleum is more active than the Barbadoes.

Oil of turpentine may be detected in petroleum, according to M. Saladin, by triturating the suspected sample with iodide of potassium and water, when, if the oil be present, the petroleum will instantly acquire a yellow colour, which is of a deeper tint, in proportion to the quantity of the adulterating oil.

Medical Properties and Uses. Petroleum is accounted a stimulating antispasmodic and sudorific. It is occasionally given in disorders of the chest, when not attended with inflammation. In Germany it has been extolled as a remedy for tape-worm. Schwartz's formula in such cases was a mixture of one part of petroleum with one and a half parts of tincture of assafetida, of which forty drops were given three times a day. Externally, petroleum is employed in chilblains, chronic rheumatism, affections of the joints, paralysis, and diseases of the skin. It is an ingredient in the popular remedy called *British oil.* (See *note,* page 521.) The dose of petroleum is from thirty drops to a small teaspoonful, given in any convenient vehicle.

The *New York petroleum,* called *Seneca oil,* is used to a considerable extent

as an external application in domestic practice. It is lighter coloured, thinner in consistence, and less sapid and odorous than the Barbadoes petroleum, and probably contains more naphtha. B.

PETROSELINUM. *U. S. Secondary.*

Parsley Root.

The root of Petroselinum sativum. *U. S.*

Persil, *Fr.;* Petersilie, *Germ.;* Prezzemolo, *Ital.;* Perexil, *Span.*

Petroselinum. *Sex. Syst.* Pentandria Digynia.—*Nat. Ord.* Apiaceæ or Umbelliferæ.

Gen. Ch. Umbels compound. *Involucres,* partial of many, general of few bractes. *Calyx* obsolete. *Fruit* ovate, contracted at the sides. Ridges five, narrow, equal, the lateral on the edge. Vittæ one to each furrow. *Albumen* plano-convex. *Lindley.*

Petroselinum sativum. Hoffmann, *Umb.* i. t. 1, f. 2; Lindley, *Flor. Med.* p. 35.—*Apium Petroselinum.* Willd. *Sp. Plant.* i. 1475; Woodv. *Med. Bot.* p. 118, t. 45. Parsley has a biennial root, with an annual, round, furrowed, jointed, erect, branching stem, which rises about two feet in height. The radical leaves are compound, pinnated in ternaries, with the leaflets smooth, divided into three lobes, and notched at the margin. In the cauline leaves, the segments of the leaflets are linear and entire. The flowers are small, pale-yellow, and disposed in terminal compound umbels, with a one or two-leaved general involucre, and partial ones composed of six or eight leaflets. The petals are five, roundish, and inflexed at their apex. The seeds (half fruits) are small, ovate, flat on one side, convex on the other, of a dark-green colour, and marked with five longitudinal ridges. They have a strong, terebinthinate odour, and a warm aromatic taste.

The plant is a native of Sardinia, and other parts of Southern Europe, and is cultivated everywhere in gardens. All parts of it contain an essential oil, to which it owes its medicinal virtues, as well as its use in seasoning. M. H. Braconnot obtained from the herb a peculiar gelatinous substance, resembling pectic acid in appearance, which he named *apiin.* It differs from pectin in being more soluble in alcohol than cold water, in not being precipitated by alcohol from its watery solution, and in being separated by acids from its alkaline solutions unaltered, whereas pectin is under these circumstances converted into pectic acid. (*Journ. de Pharm.,* 3*e sér.,* xix. 448.) It is procured by boiling the herb in water, straining the liquor, and allowing it to cool. The apiin then forms a gelatinous mass, which requires only to be washed with cold water. (*Philos. Mag.,* xxiv. 155.) The seeds are said to contain a peculiar principle, which has been named *apiol,* upon which their medicinal activity depends. (See *Journ. de Pharm.,* 3*e sér.,* xxii. 84.) The root is the part directed by the Pharmacopœia, though the fruit is at least equally efficient.

The root is spindle-shaped, about as thick as the finger, externally white, and marked with close annular wrinkles, internally fleshy and white, with a yellowish central portion. It has a pleasant smell, and a sweetish slightly aromatic taste; but loses these properties by long boiling, and by the action of time. It should be employed in the recent state.

Medical Properties and Uses. Parsley root is said to be aperient and diuretic, and is occasionally used in nephritic and dropsical affections, in connexion with more active medicines. It was highly recommended by Professor Chapman. The usual form of administration is that of strong infusion. The juice of the fresh herb has been employed as a substitute for quinia in intermittents; and the seeds, as well as their supposed active principle, have been employed with great asserted effect in the same complaint. W.

PHOSPHORUS. *Lond.*

Phosphorus.

Phosphore, *Fr.;* Phosphor, *Germ.;* Fosforo, *Ital., Span.*

This non-metallic element was discovered in 1669 by Brandt, an alchemist of Hamburg; and the process by which it was made remained a secret until 1737. At first it was obtained from putrid urine, and was exceedingly scarce and costly. In 1769, Gahn discovered it in bones, and shortly afterwards published a process by which it might be extracted from them; and his method has been followed to the present time.

Preparation. Powdered calcined bones, which consist principally of bone-phosphate of lime, are digested for twenty-four hours with two-thirds of their weight of strong sulphuric acid, previously diluted with twelve times its weight of water. The sulphuric acid separates the greater part of the lime from the phosphoric acid, and precipitates as sulphate of lime; while a superphosphate of lime remains in solution. The liquid is then strained through a linen cloth to separate the sulphate of lime, and afterwards submitted to evaporation, which causes a fresh precipitation of sulphate, requiring to be separated by a new straining. The strained solution of superphosphate is evaporated to a syrupy consistence, and then thoroughly mixed with half its weight of powdered charcoal, so as to form a soft mass, which is dried by being heated to dull redness in an iron pot. The mass when cool is quickly transferred to a coated earthenware retort, furnished with an adopter of copper, bent downwards at right angles, so as to enter a bottle with a large neck containing water, which should rise about two lines above the orifice of the adopter. The bottle is closed round the adopter with a cork, which is traversed by a small glass tube, to give exit to the gaseous products. The retort is heated in a furnace, furnished with a dome, in the most gradual manner, so as to occupy about four hours in bringing it to a red heat. Afterwards the heat is pushed vigorously, so long as any phosphorus drops into the water; and this takes place generally for from twenty-four to thirty hours. During this part of the process, the excess of acid in the superphosphate is decomposed; its oxygen combining with the charcoal, and the liberated phosphorus distilling over. A quantity of the materials sufficient to fill a quart retort will yield about a pound of phosphorus. The calcined bones of the sheep are preferred; as they contain most phosphate of lime, and are more readily acted on by the acid.

Mr. Donovan recommends the following process, in which the calcining of the bones is avoided. Digest ten avoird. pounds of bones, broken into small pieces, in six of commercial nitric acid, diluted with five gallons (Imp. meas.) of water, for a few days. Strain the liquor, and add eight pounds of acetate of lead, dissolved in water. There result acetic acid and nitrate of lime in solution, and phosphate of lead which precipitates. Wash and dry the precipitate, and reduce its bulk to one-half, by heating it red-hot in a crucible. Mix the ignited powder with one-sixth of its weight of fine charcoal powder, and distil from a coated earthenware retort in the usual way. The bones, in this process, having the phosphate of lime dissolved out of them by the nitric acid, are reduced to soft, flexible, cartilaginous masses, which may be manufactured into size or glue. The process may be conducted on a smaller scale with unburnt hartshorn shavings, which contain twice as much phosphate of lime as bone, by using the following proportions: shavings a pound avoirdupois, nitric acid seventeen ounces in a gallon of water, and of acetate of lead twenty-four ounces. From the residue of the shavings in this process may be obtained a nutritious jelly. (See an abstract of Mr. Donovan's paper in the *Am. Journ. of Pharm.*, xxiv. 167.)

Properties. Phosphorus is a semitransparent solid, without taste, but possessing an alliaceous smell. When perfectly pure it is colourless; but as usually prepared it is yellowish or reddish-yellow. It is flexible, and when cut exhibits a waxy lustre. It is insoluble in water, but dissolves sparingly in alcohol and the oils, and more freely in ether and bisulphuret of carbon. Its sp. gr. is 1·84, and its equivalent number 32 (31·02 Schroetter). It takes fire at 100°, melts at 108°, and boils at 550°, air being excluded. During its combustion, it combines with the oxygen of the air, and forms dry phosphoric acid. On account of its great inflammability, it must be kept under water. When exposed to the air it undergoes a slow combustion, emitting white vapours, which are luminous in the dark. It was found by Wöhler, in one instance, to contain one-half of one per cent. of arsenic; and, therefore, when used in forming medicinal preparations, should be tested for that metal. It also occasionally contains antimony and sulphur. The latter impurity renders it brittle.

Prof. Schroetter, of Vienna, has discovered an allotropic form of phosphorus, which he calls *red amorphous phosphorus.* It is formed when ordinary phosphorus is kept for a long time at a temperature between 419° and 482° F., in atmospheres which have no action on it, or in closed glass tubes. Red phosphorus is much more indifferent than the ordinary substance, and is more dense. It is not acted on by the air, and is insoluble in bisulphuret of carbon, alcohol, and ether, in which ordinary phosphorus is soluble. When solidified from the fused state, it is brittle, and breaks with a conchoidal fracture. Its hardness is considerable. When obtained by distillation in a non-acting gas, it is mixed with ordinary phosphorus, from which it may be freed by bisulphuret of carbon, which dissolves the ordinary phosphorus, and leaves the modification as a deep-red amorphous powder. Amorphous phosphorus is not poisonous. It is applicable to the manufacture of lucifer matches, and, as it does not take fire by friction at ordinary temperatures, may be transported with the greatest safety.

Phosphorus forms with oxygen the hypophosphorous, phosphorous, and phosphoric acids, and three varieties of the latter acid, distinguished by their containing, severally, three, two, and one equivalents of water. The only officinal combinations containing phosphorus are the "diluted phosphoric acid" of the London College, and the phosphates of iron, lime, and soda.

Medical Properties. Phosphorus, exhibited in small doses, acts as a powerful general stimulant; in large doses, as a violent irritant poison. Its action seems directed particularly to the kidneys and genital organs, producing diuresis, and excitation of the venereal appetite. The latter effect has been conclusively proved by the experiments of Alphonse Leroy, Chenevix, and Bertrand-Pelletier. From its peculiar physiological action, it is considered applicable to diseases attended with extreme prostration of the vital powers. It has been recommended in dropsy, impotency, typhoid and typhus fevers, phthisis, marasmus, chlorosis, paralysis, amaurosis, mania, &c. Those who work in phosphorus, as the manufacturers of lucifer matches, are liable to necrosis of the jaw-bones, the consequence of periostitis. The affection is probably produced by the long-continued breathing of air contaminated with phosphorus vapour, which has a local action on the teeth, gums, and jaws, and a general deteriorating effect on the blood.

The usual form for exhibiting phosphorus is in oily solution. The *Oleum Phosphoratum* or *phosphorated oil* of the Prussian Pharmacopœia is made as follows. Take of phosphorus *twelve grains;* almond oil, recently prepared, *an ounce.* Melt the phosphorus in the oil by the heat of warm water, and agitate until it appears to be dissolved. The ounce of oil takes up about four grains of phosphorus; and the dose of the solution is from five to ten drops, mixed with some mucilaginous liquid. An aromatic flavour may be given to the phosphorated oil by the addition of a few drops of oil of bergamot. Dr. R. M. Glover has pro-

posed to give phosphorus, dissolved in chloroform or cod-liver oil. Chloroform furnishes a non-inflammable solution, containing one-fourth of its weight of phosphorus. Of this solution Dr. Glover gave four or five minims, twice a day, with a drachm of ether in a wineglassful of port wine, in typhoid fever. The solution in the cod-liver oil is effected by adding the phosphorus in chips, to the oil contained in a bottle, in the proportion of half a grain to the ounce. The bottle is then immersed in hot water, and the solution effected by shaking. This mode of giving phosphorus was used by Dr. Glover in strumous cases. (See *Braithwaite's Retrospect*, Am. ed., xxvii. 246.)

Great caution is necessary in the exhibition of phosphorus, and its effects should be closely watched. It ought never to be given in substance; as, when thus administered, it is apt to produce violent irritation of the stomach. When taken in substance in a poisonous dose, two or three grains of tartar emetic should be given to dislodge it. If swallowed in the state of solution, copious draughts of cold water, containing magnesia in suspension, should be administered, in order to prevent the combustion of the phosphorus, and to neutralize any acid which may have been formed. Duflos has proposed, as an antidote, a mixture of one part of magnesia and eight of chlorine water. From experiments made on rabbits by A. Bechert, it may be inferred that this mixture would prove useful. In a case of chronic poisoning from the copious inhalation of phosphorus vapour, the principal results were a gradual decay of the sexual function, paralysis, and death at the end of three years. (*Arch. Gén.*, Feb. 1853.)

Poke Berries.

The berries of Phytolacca decandra. *U. S.*

PHYTOLACCÆ RADIX. *U. S. Secondary.*

Poke Root.

The root of Phytolacca decandra. *U. S.*

PHYTOLACCA. *Sex. Syst.* Decandria Decagynia.—*Nat. Ord.* Phytolaccæ. *Gen. Ch. Calyx* none. *Petals* five, calycine. *Berry* superior, ten-celled, ten-seeded. *Willd.*

Phytolacca decandra. Willd. *Sp. Plant.* ii. 822; Bigelow, *Am. Med. Bot.* i. 39; Barton, *Med. Bot.* ii. 213. This is an indigenous plant with a very large perennial root, often five or six inches in diameter, divided into two or three principal branches, soft, fleshy, fibrous, whitish within, and covered with a brownish cuticle. The stems, which are annual, frequently grow to the height of six or eight feet, and divide into numerous spreading branches. They are round, very smooth, green when young, but purple after the berries have ripened. The leaves are scattered, ovate-oblong, entire, pointed, smooth, ribbed beneath, and supported on short footstalks. The flowers are numerous, small, and grow in long racemes, which are sometimes erect, sometimes drooping. The corolla consists of five ovate, concave petals, folding inwards, and of a whitish colour. The germ is green. There are ten stamens, and the same number of pistils. The raceme of flowers becomes a cluster of dark purple, almost black, shining berries, flattened above and below, and divided into ten cells, each of which contains one seed.

The poke is abundant in all parts of the United States, flourishing along fences,

by the borders of woods, and especially in newly-cleared and uncultivated fields. It also grows spontaneously in the North of Africa and the South of Europe, where, however, it is supposed to have been introduced from America. Its flowers begin to appear in July, and the fruit ripens in autumn. The magnitude of the poke-weed, its large rich leaves, and its beautiful clusters of purple berries, often mingled upon the same branch with the green unripe fruit, and the flowers still in bloom, render it one of the most striking of our native plants. The young shoots are much used as food early in the spring, boiled in the manner of spinage. The ashes of the dried stems and leaves contain a very large proportion of potassa, yielding, according to Braconnot, not less than forty-two per cent. of the pure caustic alkali. In the plant the potassa is neutralized by an acid closely resembling the malic, though differing from it in some respects. The leaves, berries, and root are used in medicine, but the two latter only are mentioned in the Pharmacopœia. The root is most active. It should be dug up late in November, cut into thin transverse slices, and dried with a moderate heat. As its virtues are diminished by keeping, a new supply should be procured every year. The berries should be collected when perfectly ripe, and the leaves about the middle of summer, when the footstalks begin to redden.

The *berries* contain a succulent pulp, and yield upon pressure a large quantity of fine purplish-red juice. They have a sweetish, nauseous, slightly acrid taste, with little odour. The colouring principle of their juice is evanescent, and cannot be applied to useful purposes in dyeing, from the difficulty of fixing it. Alkalies render it yellow; but the original colour is restored by acids. The juice contains saccharine matter, and, after fermenting, yields alcohol by distillation.

The *dried root* is of a light yellowish-brown colour externally, very much wrinkled, and, when in transverse slices, exhibits on the cut surface numerous concentric rings, formed by the projecting ends of fibres, between which the intervening matter has shrunk in drying. The structure internally in the older roots is firm and almost ligneous; the colour yellowish-white, alternating with darker circular layers. There is no smell; the taste is slightly sweetish, and at first mild, but followed by a sense of acrimony. The active matter is imparted to boiling water and alcohol. From the analysis of Mr. Edward Donelly, the root appears to contain tannic acid, starch, gum, sugar, resin, fixed oil, and lignin, besides various inorganic principles. (*Am. Journ. of Pharm.*, xv. 169.)

Medical Properties and Uses. Poke is emetic, purgative, and somewhat narcotic. As an emetic it is very slow in its operation, frequently not beginning to vomit in less than one or two hours after it has been taken, and then continuing to act for a long time upon both the stomach and bowels. The vomiting produced by it is said not to be attended with much pain or spasm; but narcotic effects have been observed by some physicians, such as drowsiness, vertigo, and dimness of vision. In over-doses it produces excessive vomiting and purging, attended with great prostration of strength, and sometimes with convulsions. A case is recorded in the *Stethoscope*, for March, 1852 (ii. 134), by Dr. Geo. F. Terrill, of Hanover Co., Va., in which death was produced in a woman by eating a double handful of the berries. Free purgation followed upon the first day, after which coma set in, with great prostration, though death did not occur until after the sixth day. Poke has been proposed as a substitute for ipecacuanha; but the slowness and long continuance of its action, and its tendency to purge, wholly unfit it for the purposes which that emetic is calculated to fulfil. In small doses it acts as an alterative, and has been highly recommended in the treatment of chronic rheumatism. The dose of the powdered root, as an emetic, is from ten to thirty grains; as an alterative, from one to five grains. A saturated tincture of the berries, prepared with diluted alcohol, may be given in rheumatic cases, in the dose of a fluidrachm, three times a day. A strong infusion

of the leaves or root has been recommended in piles. An ointment, prepared by mixing a drachm of the powdered root or leaves with an ounce of lard, has been used with advantage in psora, tinea capitis, and some other forms of cutaneous disease. It occasions at first a sense of heat and smarting in the part to which it is applied. An extract made by evaporating the expressed juice of the recent leaves has been used for the same purposes, and acquired at one time considerable repute as a remedy in cancer. W.

Myrtus. *Sex. Syst.* Icosandria Monogynia.—*Nat. Ord.* Myrtaceæ.

Gen. Ch. Calyx five-cleft, superior. *Petals* five. *Berry* two to five-celled, many-seeded. *Willd.*

Myrtus Pimenta. Willd. *Sp. Plant.* ii. 973; Woodv. *Med. Bot.* p. 541, t. 194.—*Eugenia Pimenta.* De Cand. *Prodrom.* iii. 285; Lindley, *Flor. Med.* p. 76. This is a beautiful tree, about thirty feet high, with a straight trunk, much branched above, and covered with a very smooth gray bark. Its dense and ever-verdant foliage gives it at all times a refreshing appearance. The leaves, which are petiolate, vary in shape and size; but are usually about four inches long, elliptical, entire, blunt, or obtusely pointed, veined, and of a deep shining green colour. The flowers are small, without show, and disposed in panicles upon trichotomous stalks, which usually terminate the branches. The fruit is a spherical berry, crowned with the persistent calyx, and when ripe is smooth, shining, and of a black or dark-purple colour. The tree exhales an aromatic fragrance, especially during the summer months, when it is in flower.

It is a native of the West Indies, Mexico, and South America, and is abundant in Jamaica, whence its fruit received the name of *Jamaica pepper.* The berries are the officinal part. They are gathered after having attained their full size, but while yet green, and are carefully dried in the sun. When sufficiently dry, they are put into bags and casks for exportation.

Properties. The berries, as they reach us, are of different sizes, usually about as large as a small pea, round, wrinkled, umbilicate at the summit, of a brownish colour, and when broken present two cells, each containing a black hemispherical seed. They have a fragrant odour, thought to resemble that of a mixture of cinnamon, cloves, and nutmeg. Hence the name of *allspice,* by which they are best known in this country. Their taste is warm, aromatic, pungent, and slightly astringent. They impart their flavour to water, and all their virtues to alcohol. The infusion is of a brown colour, and reddens litmus paper. They yield a volatile oil by distillation. (See *Oleum Pimentæ.*) By a minute analysis, Bonastre obtained from them a volatile oil, a green fixed oil, a fatty substance in yellowish flakes, tannin, gum, resin, uncrystallizable sugar, colouring matter, malic and gallic acids, saline matters, moisture, and lignin. The green oil has the burning aromatic taste of pimento, and is supposed to be the acrid principle. Upon this, therefore, together with the volatile oil, the medical properties of the berries depend; and, as these two principles exist most largely in the shell or cortical portion, this part is most efficient. According to Bonastre, the shell contains 10 per cent. of the volatile, and 8 of the fixed oil, the seeds only 5 per cent. of the former, and 2·5 of the latter. Berzelius considers the green fixed oil of Bonastre as a mixture of volatile oil, resin, fixed oil, and perhaps a little chlorophylle.

Medical Properties and Uses. Pimento is a warm, aromatic stimulant, used in medicine chiefly as an adjuvant to tonics and purgatives, the taste of which it serves to cover, while it increases their warmth, and renders them more acceptable to the stomach. It is particularly useful in cases attended with much flatulence. It is, however, much more largely employed as a condiment than as a medicine. The dose is from ten to forty grains. A tincture of pimento has been recommended as a local application in chilblains.

PIPER. See CUBEBA.

Piper nigrum. Willd. *Sp. Plant.* i. 159; Woodv. *Med. Bot.* p. 721, t. 246; Carson, *Illust. of Med. Bot.* ii. 38, pl. 83. The pepper vine is a perennial plant, with a round, smooth, woody, articulated stem, swelling near the joints, branched, and from eight to twelve feet or more in length. The leaves are entire, broad-ovate, acuminate, seven-nerved, coriaceous, very smooth, of a dark-green colour, and attached by strong sheath-like footstalks to the joints of the branches. The flowers are small, whitish, sessile, covering thickly a cylindrical spadix, and succeeded by globular berries, which are of a red colour when ripe.

The plant grows wild in Cochin-china and various parts of India. It is cultivated on the coast of Malabar, in the peninsula of Malacca, in Siam, Sumatra, Java, Borneo, the Philippines, and many other places in the East. We are told by Crawford, that the best pepper is produced in Malabar; but Europe and America derive their chief supplies from Sumatra and Java. The plant is propagated by cuttings, and is supported by props, or by trees of various kinds planted for the purpose, upon which it is trained. In three or four years from the period of planting, it begins to bear fruit. The berries are gathered before they are all perfectly ripe, and, upon being dried, become black and wrinkled.

White pepper is the ripe berry, deprived of its skin by maceration in water and subsequent friction, and afterwards dried in the sun. It has less of the peculiar virtues of the spice than the black pepper, and is seldom employed in this country.

Properties. The dried berries are about as large as a small pea, externally blackish and wrinkled, internally whitish, of an aromatic smell, and a hot, pungent, almost fiery taste. They yield their virtues partially to water, entirely to alcohol and ether. Pelletier found them to contain a peculiar crystalline matter called piperin, an acrid concrete oil or soft resin of a green colour, a balsamic volatile oil, a coloured gummy substance, an extractive matter like that found in leguminous plants capable of being precipitated by infusion of galls, a portion of bassorin, uric and malic acids, lignin, and various salts. *Piperin* was discovered by Professor Œrsted, of Copenhagen, who considered it an organic alkali, and the active principle of pepper. Pelletier, however, utterly denied its alkaline nature and medical activity, and ascribed all the effects, supposed to have been obtained from it, to a portion of the acrid concrete oil with which it is mixed when not very carefully prepared. When perfectly pure, piperin is in

colourless transparent crystals, according to Pelletier without taste, fusible at 212°, insoluble in cold water, slightly soluble in boiling water which deposits it upon cooling, soluble in alcohol, ether, and acetic acid, decomposed by the concentrated mineral acids, with the sulphuric becoming of a blood-red colour, with the nitric, first of a greenish-yellow, then orange, and ultimately red. Christison, however, states, in his Dispensatory, that the whitest crystals he had been able to obtain were still acrid, and emitted an irritating vapour when thrown on heated iron. As ordinarily procured the crystals are yellow. Piperin consists of nitrogen, carbon, hydrogen, and oxygen; and its formula, according to Wertheim, is $N_2C_{70}H_{37}O_{10}$.* It is obtained by treating pepper with alcohol, evaporating the tincture to the consistence of an extract, submitting the extract to the action of an alkaline solution by which the oleaginous matter is converted into soap, washing the undissolved portion with cold water, separating the liquid by filtration, treating the matter left on the filter with alcohol, and allowing the solution thus obtained to evaporate spontaneously, or by a gentle heat. Crystals of piperin are deposited, and may be purified by alternate solution in alcohol or ether, and crystallization. The taste and medicinal activity of pepper probably depend mainly on the concrete oil or resin, and on the volatile oil. The concrete oil is of a deep-green colour, very acrid, and soluble in alcohol and ether. The volatile oil is limpid, colourless, becoming yellow by age, of a strong odour, and of a taste less acrid than that of the pepper. It consists of 10 eqs. of carbon and 8 of hydrogen, and forms a liquid, but not a concrete compound with muriatic acid.

Medical Properties and Uses. Black pepper is a warm carminative stimulant, capable of producing general arterial excitement, but acting with greater proportional energy on the part to which it is applied. From the time of Hippocrates it has been employed as a condiment and medicine. Its chief medicinal application is to excite the languid stomach, and correct flatulence. It was long since occasionally administered for the cure of intermittents; but its employment for this purpose had passed from the profession to the vulgar, till a few years since revived by an Italian physician, to be again consigned to forgetfulness. Piperin has also been employed in the same complaint, and has even been thought superior to sulphate of quinia; but experience has not confirmed this favourable opinion. That, in its impure state, when mixed with a portion of the acrid principle, it will occasionally cure intermittents, there can be no doubt; but it is not comparable to the preparations of bark, and is probably less active than the alcoholic extract of pepper. In intermittent fever, when the stomach is not duly susceptible to the action of quinia, as sometimes in drunkards, pepper may be found a useful adjuvant to the more powerful febrifuge. The dose of pepper is from five to twenty grains. It may be given whole or in powder; but is more energetic in the latter state. Piperin has been given in doses varying from one to six or eight grains.

Off. Prep. Confectio Piperis; Confectio Rutæ; Emplastrum Cantharidis Compositum; Extractum Piperis Fluidum. W.

* An interesting chemical investigation into the nature of piperin has been made by Wertheim, the result of which is that it probably consists of a volatile alkaline principle ($NC_{12}H_7$), combined with an electro-negative compound ($NC_{58}H_{30}O_{10}$), which, however, is thus far hypothetical. The former is obtained by distilling piperin mixed with soda and hydrate of lime, at a temperature between 300° and 320°. It is considered by Wertheim as identical with *picoline*, previously obtained by Dr. Anderson from the reaction of nitric acid on piperin, and described by him in a paper presented at the meeting of the British Association, at Edinburgh in 1850. (*Chem. Gaz.*, Aug. 1849, p. 309, from *Liebig's Annalen.*) M. Cahours has since repeated the experiments of Wertheim, and obtained the same alkaline principle, which he names *piperidine*, and for which he gives the formula $NC_{10}H_{11}$, corresponding precisely with that given by Dr. Anderson for *picoline*. According to M. Cahours, it is a colourless liquid, having a mixed odour of ammonia and pepper, a very caustic taste, and a strong alkaline reaction. It is soluble in water in all proportions, and forms crystallizable salts with several acids. (*Ibid.*, May 1, 1852, p. 167.)

PIPER LONGUM. *Lond., Ed.*

Long Pepper.

Piper longum. The unripe fruit. *Lond.* The dried spikes. *Ed.*

Poivre longue, *Fr.;* Langer Pfeffer, *Germ.;* Pepe lungo, *Ital.;* Pimienta larga, *Span.*

PIPER. See CUBEBA.

Piper longum. Willd. *Sp. Plant.* i. 161; Woodv. *Med. Bot.* p. 724, t. 247. This species of Piper differs from its congeners in having its lower leaves cordate, petiolate, seven-nerved, its upper oblong-cordate, sessile, and five-nerved; its flowers in dense, short, terminal, and nearly cylindrical spikes; and its fruit, consisting of very small one-seeded berries or grains, embedded in a pulpy matter. It is a native of South-eastern Asia, and is produced abundantly in Bengal and other parts of Hindostan. The fruit is green when immature, and becomes red as it ripens. It is gathered in the former state, as it is then hotter than when perfectly ripe. The whole spike is taken from the plant and dried in the sun.

Long pepper is cylindrical, an inch or more in length, indented on its surface, of a dark-gray colour, a weak aromatic odour, and a pungent fiery taste. M. Dulong found its chemical composition to be closely analogous to that of black pepper. Like that it contains *piperin*, a concrete oil or soft resin upon which its burning acrimony depends, and a volatile oil to which it probably owes its odour. Its medical virtues are essentially the same as those of black pepper; but it is considered inferior to that spice, and is seldom used.

PIX. *Lond.*

Pitch.

Dry bitumen prepared from tar. *Lond.*

Off. Syn. PIX ARIDA. Pitch: from various species of Pinus and Abies. *Ed.*

This is the solid black mass left after the evaporation of the liquid parts of tar. It was formerly called *pix nigra* or *black pitch.* It has a shining fracture, softens and becomes adhesive with a moderate heat, melts in boiling water, and consists of the resin of the pine unaltered, and of various empyreumatic resinous products which have received the name of *pyretin.* (*Berzelius, Trait. de Chim.*, vi. 641 and 680.) It appears to be very gently stimulant or tonic, and has been used internally in ichthyosis and other cutaneous diseases, and recently with great advantage in piles. The dose is from ten grains to a drachm given in pills. Pitch is also used externally in the form of ointment.

Poix de Bourgogne, Poix jaune, Poix blanche, *Fr.;* Burgundisches Pech, *Germ.*

The genus Pinus of Linnæus has been divided into three genera, viz., *Pinus, Abies,* and *Larix;* the first including the pines, the second the firs and spruces,

and the third the larches. We follow the Pharmacopœias in adopting this division.

Abies. *Sex. Syst.* Monœcia Monadelphia. — *Nat. Ord.* Pinaceæ or Coniferæ. *Gen. Ch.* Male flowers. *Catkins* solitary, not racemose; *Scales* staminiferous at the apex. *Stamens* two, with one-celled anthers. Females. *Catkins* simple. *Ovaries* two. *Stigmas* glandular. *Cone* with imbricated scales, which are thin at the apex, and rounded. *Cotyledons* digitate-partite. *Leaves* solitary in each sheath. *De Cand.*

Abies excelsa. De Candolle. — *A. communis.* Loudon's *Encyc. of Plants.* — *Pinus Abies.* Willd. *Sp. Plant.* iv. 506; Woodv. *Med. Bot.* p. 4, t. 2. The *Norway spruce* is a very lofty tree, rising sometimes one hundred and fifty feet in height, with a trunk from three to five feet in diameter. The leaves, which stand thickly upon the branches, are short, obscurely four-cornered, often curved, of a dusky green colour, and shining on the upper surface. The male aments are purple and axillary, the female of the same colour, but usually terminal. The fruit is in pendent, purple, nearly cylindrical strobiles, the scales of which are oval, pointed, and ragged at the edges.

This tree is a native of Europe and Northern Asia. Though designated as the source of Burgundy pitch, it furnishes but a part of the substance sold under that name by the druggists. Tingley asserts that the real Burgundy pitch is obtained from the *Abies picea*, or European silver fir tree; and the same fact is stated by Fée. According to Geiger, who is probably correct, it is procured from both species. To obtain the *pitch*, portions of the bark are removed so as to lay bare the wood, and the flakes of concrete resinous matter which form upon the surface of the wound, having been detached by iron instruments, are melted with water in large boilers, and then strained through coarse cloths. It is called Burgundy pitch from the province of that name in the East of France. We are told that the greater portion is collected in the neighbourhood of Neufchatel.

From various species of pine, in different parts of Europe, a similar product is obtained and sold by the same name. It is prepared by removing the juice which concretes upon the bark of the tree, or upon the surface of incisions, called *galipot* by the French, and purifying it by melting and straining, either through cloth or a layer of straw. A *factitious Burgundy pitch* is made by melting together common pitch, resin, and turpentine, and agitating the mixture with water, which gives it the requisite yellowish colour. Its odour is different from that of the genuine.

As brought to this country, Burgundy pitch is generally mixed with impurities, which require that it should be melted and strained before being used. In its pure state it is hard, brittle, quite opaque, of a yellowish or brownish-yellow colour, and a weak terebinthinate taste and odour. It is very fusible, and at the heat of the body softens and becomes adhesive. It differs from turpentine in containing a smaller proportion of volatile oil.

Thus. *Frankincense.* Under the name of *Thus*, the London and Dublin Colleges direct the concrete juice of the *spruce fir*, as taken immediately from the bark of the tree without any preparation. The London College recognises also Pinus palustris as one of its sources. As sold in London it is in all probability derived chiefly if not exclusively from the latter tree, being in fact nothing more than our common turpentine, perfectly dry and brittle. (See *Terebinthina.*) It is in solid, brittle tears, of a yellowish or brownish-yellow colour on the outside, and paler within, and emits an agreeable odour when burned. It softens and becomes adhesive at the temperature of the body.

Medical Properties and Uses. Applied to the skin in the shape of a plaster, Burgundy pitch acts as a gentle rubefacient, producing a slight degree of inflammation and serous effusion without separating the cuticle. Sometimes it excites

a papillary or vesicular eruption; and we have known it to act upon the surface as a violent poison, giving rise to severe pain, swelling, and redness, followed by vesication and even ulceration. It is used chiefly in slight chronic pains of a rheumatic character, or in chronic affections of the chest or abdomen, which call for a gentle but long-continued revulsion to the skin. The resinous exudation of the spruce fir (*thus or frankincense*) is used only as an ingredient of plasters.

PIX CANADENSIS. *U. S.*

Canada Pitch.

The prepared concrete juice of Abies Canadensis. *U. S.*

Abies. See PIX BURGUNDICA.

Abies Canadensis. Michaux, *N. Am. Sylv.* iii. 185.—*Pinus Canadensis.* Willd. *Sp. Plant.* iv. 505. This is the *hemlock spruce* of the United States and Canada. When of full growth it is often seventy or eighty feet high, with a trunk two or three feet in diameter, and of nearly uniform dimensions for two-thirds of its length. The branches are slender, and dependent at their extremities. The leaves are very numerous, six or eight lines long, flat, denticulate, and irregularly arranged in two rows. The strobiles are ovate, little longer than the leaves, pendulous, and situated at the ends of the branches.

The tree is abundant in Canada, Nova Scotia, and the more northern parts of New England; and is found in the elevated and mountainous regions of the Middle States. Its bark abounds in the astringent principle, and is much used for tanning in the northern parts of the United States. It contains much less juice than some other of the Pinaceæ; and very little flows from incisions made into its trunk. But in the trees which have attained their full growth, and are about or have begun to decay, the juice exudes spontaneously, and hardens upon the bark, in consequence of the partial evaporation or oxidation of its volatile oil. The bark thus incrusted is stripped from the tree, broken into pieces of convenient size, and boiled in water. The pitch melts, rises to the surface, is skimmed off, and is still further purified by a second boiling in water. It is brought to Philadelphia from the north of Pennsylvania, in dark-coloured brittle masses, which, on being broken, exhibit numerous minute fragments of bark, interspersed through their substance. From these it is purified in the shops by melting and straining through linen or canvas. (Ellis, *Journ. of Phil. Col. of Pharm.*, ii. 18.)

Thus prepared it is hard, brittle, quite opaque, of a dark yellowish-brown colour, which becomes still darker by exposure to the air, of a weak peculiar odour, and scarcely any taste. It softens and becomes adhesive with a moderate heat, and melts at 198° F. Its constituents are resin and a minute proportion of volatile oil. It is commonly known by the incorrect name of *hemlock gum.*

Medical Properties and Uses. Canada pitch is a gentle rubefacient, closely analogous to Burgundy pitch in its properties, and employed for precisely the same purposes. It is, however, more readily softened by heat, and is sometimes almost too soft for convenient application at the temperature of the body. A volatile oil obtained from Abies Canadensis, and called *oil of hemlock*, has been employed to produce abortion, with the effect of endangering the life of the female. (J. S. Paige, *N. Y. Journ. of Med.*, viii. 184.) W.

PIX LIQUIDA. *U. S., Lond., Ed., Dub.*

Tar.

The impure turpentine procured by burning from the wood of Pinus palustris and other species of Pinus. *U. S.* Pinus sylvestris and other species. Liquid bitumen prepared from the wood by fire. *Lond.* Tar from various species of Pinus and Abies. *Ed.* Tar from Pinus sylvestris. *Dub.*

Goudron, *Fr.;* Theer, *Germ.;* Pece liquida, *Ital.;* Alquitran, *Span.*

The tar used in this country is prepared from the wood of various species of pine, particularly *Pinus palustris* of the Southern States, the *P. australis* of Michaux. (See *Terebinthina.*) The dead wood is usually selected, because, when vegetation ceases, the resinous matter becomes concentrated in the interior layers. The wood is cut into billets of a convenient size, which are placed together so as to form a large stack or pile, and then covered with earth as in the process for making charcoal. The stack is built upon a small circular mound of earth previously prepared, the summit of which gradually declines from the circumference to the centre, where a small cavity is formed, communicating by a conduit with a shallow ditch surrounding the mound. Fire is applied through an opening in the top of the pile, and a slow combustion is maintained, so that the resinous matter may be melted by the heat. This runs into the cavity in the centre of the mound, and passes thence by the conduit into the ditch, whence it is transferred into barrels. Immense quantities of tar are thus prepared in North Carolina and the south-eastern parts of Virginia, sufficient, after supplying our own consumption, to afford a large surplus for exportation.

Considerable quantities of tar have also been prepared in the lower parts of New Jersey, in some portions of New England, and in Pennsylvania west of the Alleghany mountains, from the *Pinus rigida,* or pitch pine, and perhaps from some other species.

Properties. Tar has a peculiar empyreumatic odour, a bitterish, resinous, somewhat acid taste, a colour almost black, and a tenacious consistence intermediate between that of a liquid and solid. It consists of resinous matter, united with acetic acid, oil of turpentine, and various volatile empyreumatic products, and coloured with charcoal. By distillation it yields an acid liquor called *pyroligneous acid* (see *Acidum Aceticum*), and an empyreumatic oil called *oil of tar;* and what is left behind is *pitch.* The empyreumatic oil has been ascertained by Dr. Reichenbach, of Moravia, to contain, besides oil of turpentine, six distinct principles, which he has named *paraffine, eupione, creasote, picamar, capnomor,* and *pittacal.* Of these, only picamar and creasote merit particular attention; the former as the principle to which tar owes its bitterness, the latter as the one upon which it probably depends chiefly for its medical virtues. (See *Creasotum.*) Tar yields a small proportion of its constituents to water, which is thus rendered medicinal, and is employed under the name of *tar water.* It is dissolved by alcohol, ether, and the volatile and fixed oils.

Medical Properties and Uses. The medical properties of tar are similar to those of the turpentines. It is occasionally used with advantage in chronic catarrhal affections, and complaints of the urinary passages. Little benefit can be expected from it in genuine phthisis, in the treatment of which it was formerly recommended. Dr. Bateman employed it advantageously as an internal remedy in ichthyosis. Its vapour, inhaled into the lungs, has been found serviceable in numerous cases of bronchial disease. Its effects in this way are most conveniently obtained by placing a cup containing tar or oil of tar in a small water-bath, over a common nurse-lamp, and thus impregnating the air of the chamber.

Externally applied, in the state of ointment, tar is a very efficient remedy in tinea capitis or scaldhead, and in some cases of psoriasis; and has been used with advantage in foul or indolent ulcers, and some other affections of the skin.

It may be used in the form of tar water, or in substance made into pills with wheat flour, or mixed with sugar in the form of an electuary. The dose is from half a drachm to a drachm, and may be repeated so as to amount to three or four drachms daily.

Tar water (*Aqua Picis Liquidæ*) may be prepared by stirring a pint of tar with half a gallon of water for fifteen minutes, then allowing the tar to subside, and straining the liquid. Water takes from tar a small portion of acetic acid, empyreumatic oil, and resinous matter, acquiring a sharp empyreumatic taste, and the colour of Madeira wine. Thus impregnated it is stimulant and diuretic, and may be taken in the quantity of from one to two pints daily. It is also used as a wash in chronic cutaneous affections, and is said to have proved beneficial, by injection into the bladder, in some cases of chronic cystitis.*

Off. Prep. Unguentum Picis Liquidæ. W.

PLUMBUM.

Lead.

Plomb, *Fr.*; Blei, *Germ.*; Lood, *Dutch*; Plombo, *Ital.*; Plomo, *Span.*; Chumbo, *Port.*

Lead is not officinal in its metallic state; but enters into a number of important medicinal preparations. It occurs in nature in three principal states—as an oxide, as a sulphuret called *galena*, and in saline combination, forming the native sulphate, phosphate, carbonate, chromate, molybdate, tungstate, and arseniate of lead. The oxide is rare, but galena is exceedingly abundant and diffused, and is the ore from which nearly all the lead of commerce is extracted. The process of extraction consists in melting the ore in contact with charcoal. Mines of galena occur in different parts of the world, but the richest and most extensive are found in this country. The lead region of the United States extends in length from the Wisconsin in the north to the Red river of Arkansas in the south, and in breadth about one hundred and fifty miles.

Properties. Lead is a soft, bluish-gray, and very malleable metal, presenting a bright surface when newly melted or cut. It has a perceptible taste, and a peculiar smell when rubbed. It undergoes but little change in the air, but is acted on by the combined influence of air and water, which give rise to a hydrated protoxide, which is afterwards changed, in part, into carbonate, by absorbing carbonic acid from the atmosphere. This chemical effect on the metal is greater in proportion as the water is purer. (See *page* 110.) Its sp. gr. is 11·4, melting point about 612°, and equivalent number 103·6. Exposed to a stream of oxygen on ignited charcoal, it burns with a blue flame, throwing off dense yellow fumes. The best solvent of lead is nitric acid; but the presence of sulphuric acid destroys, and that of muriatic acid lessens its solvent power, on

* *Tar Beer or Wine of Tar.* A preparation under this name has been used to some extent in Philadelphia in pulmonary affections. The following is the formula recommended by Prof. Procter. Take of *ground malt*, *honey*, and *tar*, each a pound; *yeast* half a pint. Mix the malt and honey with six pints of water in an earthen vessel; keep the mixture for three hours, with occasional stirring, at the temperature of 150° F.; then allow it to cool to 80° F., and add the yeast. Sustain the fermentation for thirty-six hours by a heat between 70° and 80°, then decant the supernatant liquid, add the tar gradually to the dregs, stirring constantly, so as to make a uniform mixture, and return the decanted fluid to the vessel. Stir the whole occasionally for a week, adding water so as to preserve the original measure; then strain with strong expression, allow the expressed liquor to stand until it becomes nearly clear by subsidence, and finally filter through paper. (*Am. Journ. of Pharm.* xxii. 111.)

account of the insolubility of the sulphate and chloride of lead. Lead forms five oxides, a dioxide, protoxide, sesquioxide, deutoxide, and red oxide. The *dioxide* consists of two equivalents of lead and one of oxygen. The *protoxide*, called in commerce *massicot*, may be obtained by calcining, in a platinum crucible, the subnitrate of lead, formed by precipitating a solution of the nitrate by ammonia. On a large scale it is manufactured by exposing melted lead to the action of the air. Its surface becomes encrusted with a gray pellicle, which, being scraped off, is quickly succeeded by another; and the whole of the metal, being in this way successively presented to the air, becomes converted into a greenish-gray powder, consisting of protoxide and metallic lead. This, by exposure to a moderate heat, absorbs more oxygen, and is converted entirely into protoxide. This oxide has a yellow colour, and is the only oxide of lead capable of forming salts with the acids. It consists of one eq. of lead 103·6, and one of oxygen 8 = 111·6. A variety of the protoxide called *litharge* is very much used in pharmacy, and is officinal in all the Pharmacopœias. (See *Plumbi Oxidum Semivitreum.*) The *sesquioxide*, discovered by Winckelblech, is unimportant. The *deutoxide*, called also *puce* oxide from its *flea*-brown colour, may be obtained by treating red lead with nitric acid. The acid takes up the protoxide and leaves the deutoxide, which may be purified by washing with boiling water. It is a tasteless powder, of a dark-brown colour. When heated to redness it loses half its oxygen and becomes protoxide. It consists of one eq. of lead 103·6, and two of oxygen 16 = 119·6. The *red oxide*, called in commerce *minium* or *red lead*, is described under another head. (See *Plumbi Oxidum Rubrum.*) Lead combines with iodine, forming the officinal iodide of lead. The acetate, carbonate, and nitrate are also officinal.

The best tests of lead are sulphuretted hydrogen, and a solution of iodide of potassium. The former produces a black precipitate of sulphuret of lead, the latter, a yellow one of iodide of lead.

Medical Properties and Uses. The effects of lead in its various combinations are those of a sedative and astringent. It is used internally for the purpose of reducing vascular action, and restraining inordinate discharges; and externally as an abater of inflammation. When introduced into the system in a gradual manner, either by working in the metal, or by taking it in small and frequently repeated doses, it acts injuriously on the nervous system, producing a peculiar colic, called *lead colic*, sometimes apoplectic symptoms, and occasionally palsy, which is almost always partial, and affects for the most part the upper extremities. In some instances salivation is produced, and, according to Dr. Henry Burton, the constitutional effects of the metal are indicated by a narrow lead-blue line at the edge of the gum, round two or more of the teeth, as a constant and early sign. According to Mialhe lead gains access to the circulation by means of the chlorides of the alkalifiable metals in the alimentary canal, which form with the lead, a soluble double chloride of lead and potassium or of lead and sodium. The treatment necessary in lead colic is given under *carbonate of lead.* Lead palsy is usually attended with dyspepsia, constipation, tendency to colic, lassitude, and gloominess of mind; and is best treated by tonics, aperients, exercise, and avoidance of the cause of the disease. The poisonous effects of an over-dose of the lead preparations are to be combated by emetics, if free vomiting has not previously occurred, by the exhibition of sulphate of magnesia or sulphate of soda, and by opium. The sulphates mentioned as purgatives have been recommended, under the impression that they acted as antidotes by forming sulphate of lead. It is probable that they lessen the poisonous effects of the soluble salts of lead; but the sulphate, though insoluble in water, may be, to some extent, soluble in the gastric juice; and, so far as its external use in the form of ointment is concerned, it has been found by Flandin to prove poisonous to the inferior animals.

In chronic poisoning by lead, warm sulphuretted baths, formed by dissolving four ounces of sulphuret of potassium in thirty gallons of water, in a wooden tub, are useful. These baths cause discoloration of the skin, from the formation of sulphuret of lead, and should be repeated every few days, until this effect ceases to be produced. During each bath, the patient should be well rubbed with a flesh-brush, and soap and water, in order to remove the discoloration. By proceeding in this way, the lead on the skin, or in its pores, is rendered insoluble and inert, and at the same time removed. Dr. Melsens praises iodide of potassium in chronic lead poisoning, the medicine having the effect of rendering the lead soluble, and of eliminating it from the system principally by the urine.

Orfila has determined, by experiments on dogs, the appearance exhibited by the mucous membrane of the stomach, after the use of small doses of the salts of lead. After the action of such doses for two hours, dull white points are visible on the membrane, sometimes in rows and sometimes disseminated, and evidently consisting of the metal, united with the organic tissue. If the animal be allowed to live for four days, the same spots may be seen with the magnifier; and if sulphuretted hydrogen be applied to the surface, they are instantly blackened. (*Archives Gén., 3e série*, iv. 244.)

According to M. Gendrin, sulphuric acid, prepared like lemonade, and used both internally and externally, is a prophylactic against the poisonous effects of lead, especially the lead colic. It may be supposed to act by forming the comparatively inert sulphate of lead with the poison. Mr. Benson, a manager of white lead works at Birmingham, has tried this acid, and finds it a preventive of lead colic in his establishment, where it was exceedingly prevalent before its employment. He uses it as an addition to ginger beer, to which bicarbonate of soda is also added to render it brisk, but not in sufficient quantity to prevent a considerable portion of the acid remaining in excess. (*London Lancet*, Dec., 1842.) On the other hand, the powers of sulphuric acid in preventing the poisonous effects of lead are positively denied by Dr. A. Grisolle, Dr. Melsens, and other authorities. Dr. Grisolle recommends that workmen employed in lead manufactories should use frequent baths, avoid intemperance, and always eat before they enter upon their work in the morning. He supposes that, in a great majority of cases, the metal is introduced into the system through the stomach by means of the saliva or food. After acute poisoning by lead, the metal has been found in the liver and brain. Indeed, it may be detected in all the organs, a long time after the ingestion of the poison.

The following table embraces all the officinal preparations of lead.

Acetate of Lead.

Sugar of Lead; Saccharum Saturni, Cerussa acetata, *Lat.;* Acétate de plomb, Sucre de plomb, Sel de Saturne, *Fr.;* Essigsaures Bleioxyd, Bleizucker, *Germ.;* Zucchero di Saturno, *Ital.;* Azucar de plomo, *Span.*

Of the Pharmacopœias commented on in this work, the Edinburgh alone gives a formula for preparing this salt. In the other Pharmacopœias it is more properly placed in the catalogue of the Materia Medica.

Preparation. Sugar of lead is obtained by two methods. By one method, thin plates of lead are placed in shallow vessels filled with distilled vinegar, in such a manner as to have a part of each plate rising above the vinegar; and these are turned from time to time, so as to bring different portions of the metallic surface in contact with the air. The metal, after becoming protoxidized, dissolves in the vinegar to saturation, and the solution is evaporated to the point of crystallization. This process is a slow one, but furnishes a salt which is perfectly neutral. The other method consists in dissolving, by the assistance of heat, litharge, or the protoxide of lead obtained by calcination, in an excess of distilled vinegar or of purified pyroligneous acid, contained in leaden boilers. The oxide is quickly dissolved, and, when the acid has become saturated, the solution is transferred to other vessels to cool and crystallize. The crystals having formed, the mother waters are decanted, and, by a new evaporation, made to yield a new crop. These are generally yellow, but may be rendered white by repeated solutions and crystallizations.

Sugar of lead is extensively manufactured in Germany, Holland, France, and England, as well as in the United States. It is principally consumed in the arts of dyeing and calico-printing, in which it is employed to form with alum the acetate of alumina, to act as a mordant.

Properties. Acetate of lead is a white salt, crystallized in brilliant needles, which have the shape of long prisms, terminated by dihedral summits. Its taste is at first sweet and afterwards astringent. Exposed to the air it effloresces slowly. It dissolves in four times its weight of cold, and in a much smaller quantity of boiling water. It is soluble also in alcohol. Its solution in common water is turbid, in consequence of the formation of carbonate of lead with the carbonic acid which such water always contains. This turbidness may be removed by the addition of a small proportion of vinegar, or of dilute acetic acid. In pure distilled water, free from carbonic acid, it ought to dissolve entirely, and form a clear solution. Sulphuric acid, when added to a solution of acetate of lead, produces instantly a precipitate of sulphate of lead; and the disengaged acetic acid gives rise to vapours having the smell of vinegar. The salt, when heated, first fuses and parts with its water of crystallization, and afterwards is decomposed, yielding acetic acid and pyroacetic spirit (acetone), and leaving a residue of charcoal and reduced lead. An important property of sugar of lead is its power of dissolving a large quantity of protoxide of lead. (See *Liquor Plumbi Subacetatis.*) It consists of one eq. of acetic acid 51, one of protoxide of lead 111·6, and three of water 27=189·6.

Incompatibles. Acetate of lead is decomposed by all acids, and by those soluble salts, the acids of which produce with protoxide of lead insoluble or sparingly

soluble compounds. Acids of this character are the sulphuric, muriatic, citric, and tartaric. It is also decomposed by lime-water, and by ammonia, potassa, and soda; the last two, if added in excess, dissolving the precipitate at first formed. It is decomposed by hard water, in consequence of the sulphate of lime and common salt which such water usually contains. With sulphuretted hydrogen, it gives a black precipitate of sulphuret of lead; with iodide of potassium, a yellow one of iodide of lead; and with a carbonated alkali, a white one of carbonate of lead.

Medical Properties and Uses. Acetate of lead, in medicinal doses, is a powerful astringent and sedative; in over-doses, an irritant poison. It has sometimes been given in pretty large doses in regular practice without any bad effects, and cases are on record where a quarter of an ounce has been swallowed without proving fatal. On the other hand, it sometimes produces colica pictonum when given in medicinal doses, though taken with acetic acid to ward off its deleterious effects. It is proper to remark, however, that the immediate effects of an over-dose are often escaped by prompt and spontaneous vomiting; and that the remote constitutional effects are not apt to occur, so long as the evacuations from the bowels are not materially diminished. The principal diseases in which it has been exhibited are hemorrhages, particularly from the lungs, intestines, and uterus. Its effect in restraining the discharge of blood is admitted to be very powerful. It has also been used with advantage in certain forms of dysentery and diarrhœa, and has been recommended in particular stages of cholera infantum. Combined with opium, it is well suited to the treatment of the diarrhœa occurring in phthisis. It sometimes proves a valuable remedy in checking vomiting. Dr. Irvine, of Charleston, recommends it to compose the irritability of the stomach in yellow fever; and Dr. Davis, of Columbia, S. C., used it with benefit in the irritable stomach attendant on bilious fever. It has been much extolled by the German practitioners in dothinenteritis, or the typhoid fever attended with ulcerations of the intestines. In some of these cases it was advantageously combined with carbonate of ammonia. The same practitioners have strongly recommended it in aneurism of the aorta, and Dupuytren, on their report of its efficacy, tried it in several cases, and with marked effect in diminishing the size of the aneurismal tumour. (*Archives Gén.*, 3*e sér.*, v. 445.) One of the authors has imitated the practice in aneurism of the aorta, and in enlargement of the heart, and with encouraging results. It has been employed by Drs. Neuhold and Hasserbronc, with remarkable success, in strangulated hernia, used in enemata, containing ten grains of the salt dissolved in six fluidounces of tepid water, and repeated every two hours. In mercurial salivation, M. Brachet, of Lyons, found sugar of lead very efficacious, administered in grain pills, night and morning. Several cases of severe salivation of several months' duration, which had resisted the use of opium, purgatives, &c., were speedily relieved by the remedy. The solution is frequently used as a collyrium; and, applied by means of cloths, or mixed with crumb of bread, it forms a good application to superficial inflammation. It is sometimes advantageous to associate opium with the solution, in which case the meconate of morphia of the opium is decomposed, with the result of forming acetate of morphia in solution, and meconate of lead which precipitates. A convenient lotion, containing an excess of acetate of lead, may be formed by adding four grains of the acetate and four of opium to a fluidounce of water.

When employing this medicine, the practitioner should always bear in mind that, when long continued in small doses, it is apt to produce dangerous constitutional effects. These are chiefly of two kinds; 1. an affection of the alimentary canal, attended with severe pain and obstinate constipation, called *colica pictonum*, or *lead colic*; 2. a chronic affection of the muscles, especially of the extensors of the upper extremities, characterized by an excessive wasting of

these organs, and denominated *lead palsy*. Both these affections are apt to be excited in those artisans who work in lead. The approach of these dangerous constitutional symptoms is said to be indicated by a narrow lead-blue line at the edge of the gums. (See *page* 567.)

The dose of sugar of lead is from one to three grains, in the form of pill, repeated every two or three hours. It is generally given combined with opium. The solution for external use may be made by dissolving from two to three drachms in a pint of water; and if it be wanted clear, a fluidrachm of vinegar, or of dilute acetic acid may be added, which immediately dissolves the carbonate of lead, to which its turbidness is owing. When the skin is denuded of the cuticle, the solution should be weaker. The usual strength of the solution as a collyrium is from one to two grains to the fluidounce of distilled water.

PLUMBI CARBONAS. *U. S., Ed., Dub.*

Carbonate of Lead.

White lead, Ceruse; Céruse, Carbonate de plomb, Blanc de plomb, Blanc de céruse, *Fr.;* Bleiweiss, *Germ.;* Cerussa, *Lat., Ital.;* Albayalde, *Span.*

Preparation. Carbonate of lead is prepared by two principal methods. By one method it is obtained by passing a stream of carbonic acid through a solution of subacetate (trisacetate) of lead. The carbonic acid combines with the excess of protoxide and precipitates as carbonate of lead, while a neutral acetate remains in solution. This, by being boiled with a fresh portion of protoxide, is again brought to the state of subacetate, when it is treated with carbonic acid as before. In this way the same portion of acetate repeatedly serves the purpose of being converted into subacetate, and of being decomposed by carbonic acid. The carbonate obtained is washed, dried with a gentle heat, and thrown into commerce. This process, which produces white lead of the first quality, was invented and made public by Thenard, about the year 1802, and is that which is usually pursued in France and Sweden.

A modification of the process of Thenard is now pursued by some manufacturers in England. It consists in mixing litharge with a hundredth part of acetate of lead, and subjecting the mixture, previously moistened with very little water, to a stream of carbonic acid. (*Pelouze.*)

The other method, which consists in exposing lead to the vapours of vinegar, originated in Holland, and is usually pursued in England and the United States; but in England, with some modifications which are not well known. We shall describe this process as pursued by our own manufacturers. The lead is cast into thin sheets, made by pouring the melted lead over an oblong sheet-iron shovel, with a flat bottom, and raised edges on its sides, which is held in a slanting direction over the melting-pot. As many of these sheets are then loosely rolled up as may be sufficient to form a cylinder five or six inches in diameter, and seven or eight high, which is placed in an earthen pot containing about half a pint of vinegar, and having within, a few inches from the bottom, three equidistant projecting portions in the earthenware, on which the cylinder of lead is supported, in order to keep it from contact with the vinegar. The pots thus prepared are placed side by side, in horizontal layers, in a building roughly constructed of boards, with interstices between them. The first layer is covered with boards, on which a stratum of tan or refuse straw from the stables is strewed; and fresh layers of pots, boards, and straw are successively placed until the whole

building is filled. The sides also are enclosed with straw. The layers of pots contained in one building, called a stack, are allowed to remain undisturbed for about six weeks, at the end of which time they are unpacked, and the cylinder of sheet-lead in each pot, though still retaining its shape, is found almost entirely converted into a flaky, white, friable substance, which is the white lead. This is separated from the lead yet remaining in the metallic state, ground in water, whereby it is washed and reduced to fine powder, and finally dried in long shallow reservoirs, heated by steam.

Pelouze has succeeded in explaining all these processes on the same general principles. In Thenard's process, it is admitted that the same portion of acetate of lead repeatedly unites with protoxide, and gives it up again to carbonic acid to form the carbonate. In the modified English process, referred to above, he supposes that the one per cent. of acetate of lead combines with sufficient litharge to convert it into subacetate, which immediately returns to the state of neutral acetate, by yielding up its excess of base to form the carbonate with the carbonic acid. The acetate is now ready to combine with a fresh portion of litharge, to be transferred to the carbonic acid as before; and thus this small proportion of acetate, by combining with successive portions of the litharge, finally causes the whole of it to unite with the carbonic acid. In the Dutch process, Pelouze has rendered it almost certain, that none of the oxygen or carbonic acid of the carbonate is derived from the vinegar. Here he supposes that the heat, generated by the fermentation of the straw or tan, volatilizes the vinegar, the acetic acid of which, with the assistance of the oxygen of the air, forms with the lead a small portion of subacetate. This, by reacting with the carbonic acid resulting from the decomposition of the straw or tan, or derived from the atmosphere, forms carbonate of lead, and is reduced to the state of neutral acetate. The neutral acetate returns again to the state of subacetate, and, by alternately combining with and yielding up the protoxide, causes the whole of the lead to be finally converted into carbonate.

The temperature of the stacks of pots in the Dutch process is about 113°. If it fall below 95°, a part of the lead escapes corrosion, and if it rise above 122°, the product is yellow. The form of acetic acid usually employed in this process is common vinegar; but the variable nature of that liquid as to strength and purity is an objection to its use; and, accordingly, other forms of the acid have been substituted for it with advantage, as, for example, the purified acetic acid from wood in a diluted state. For further information in relation to the different processes proposed or pursued for making white lead, the reader is referred to a paper by Prof. J. C. Booth, in the *Journal of the Franklin Institute* for Jan. 1842.

Properties. Carbonate of lead is a heavy, opaque substance, in powder or friable lumps, insoluble in water, of a fine white colour, inodorous and nearly insipid. Its beauty as a pigment depends in a great measure on the purity of the lead from which it is manufactured. It is wholly soluble, with effervescence in dilute nitric acid. Exposed to heat it becomes yellow, and with charcoal is reduced to the metallic state. It is sometimes adulterated with the sulphates of baryta, lime, and lead, particularly the former. M. Louyet has examined samples of French white lead, containing considerably more than half their weight of sulphate of baryta. These sulphates, if present, are left undissolved by nitric acid. Chalk or whiting is another adulteration. This may be detected by adding to the nitric solution of the white lead an excess of potassa, which will redissolve the protoxide of lead first thrown down, but leave a white powder of lime. Neutral carbonate of lead consists of one eq. of carbonic acid 22, and one of protoxide of lead 111·6=133·6. Commercial white lead is a compound of the carbonate and hydrate of lead. Mulder and Hochstetter make its formula to be $2(PbO,CO_2)+PbO,HO$.

Medical Properties and Uses. White lead is ranked in the materia medica as an astringent and sedative. It is employed externally only, being used, in the form of ointment, as an application to ulcers, and to inflamed and excoriated surfaces. (See *Unguentum Plumbi Carbonatis.*) It is recommended in scalds and burns by Prof. Gross, and Dr. Henry, of Iowa, bears testimony to its efficacy. The white lead is first brought to the consistence of cream by linseed oil, and then brushed over the inflamed surface. (*Boston Med. and Surg. Journ.*, xlvi. 73.) Its external use, however, is viewed by many practitioners as dangerous, on account of the risk of absorption; but the danger is certainly overrated, as we have the testimony of respectable physicians that they frequently employ it in this way, without the least unpleasant result.

Of the different preparations of lead, the carbonate is considered to be the most poisonous. Being extensively manufactured for the purposes of the arts, it is that preparation which, by slow absorption, most frequently produces the peculiar spasmodic colic, called *colica pictonum.* This disease is characterized by pain about the region of the navel, and by obstinate constipation, attended with a frequent desire to evacuate the bowels, and is supposed to depend upon a spasmodic constriction of the intestinal tube, particularly of the colon. The principal indications in the treatment are, first to relax the spasm, and then to evacuate the bowels by the gentlest means. Opium and mild aperients, used alternately, are accordingly the best remedies, and among the latter castor oil and sulphate of magnesia are to be preferred. Indeed, the latter appears peculiarly adapted to the case; for, while it acts as an aperient, it operates to some extent as a counterpoison, by forming the sulphate of lead with any soluble compound of the metal which it may meet with in the bowels. Calomel is often useful; and, if it happen to induce ptyalism, the complaint immediately yields. By some practitioners alum is deemed almost a specific in colica pictonum.

PLUMBI NITRAS. *U. S., Ed., Dub.*

Nitrate of Lead.

This salt has been introduced into the Materia Medica of the U. S. Pharmacopœia, chiefly as one of the substances employed in the preparation of iodide of lead. The Edinburgh and Dublin Colleges give processes for its preparation.

"Take of Litharge *four ounces and a half;* Diluted Nitric Acid *a pint* [Imperial measure]. Dissolve the Litharge to saturation with the aid of a gentle heat. Filter, and set the liquor aside to crystallize. Concentrate the residual liquid to obtain more crystals." *Ed.*

"Take of Litharge, in fine powder, *five ounces* [avoirdupois]; Pure Nitric Acid *two fluidounces;* Distilled Water *three pints* [Imp. meas.]; Dilute Nitric Acid, a sufficient quantity. To the litharge, placed in a porcelain dish, add the acid with a pint and a half of the water, and, applying a sand heat, and occasionally stirring the mixture, evaporate the whole to dryness. Upon the residue boil the remainder of the water, clear the solution by filtration, and, having acidulated it by the addition of a few drops of the dilute nitric acid, evaporate until a pellicle begins to form. The heat being now withdrawn, crystals will form on the cooling of the solution, which should be dried on blotting paper in a warm atmosphere, and preserved in a close bottle." *Dub.*

In these processes the nitric acid unites directly with the protoxide of lead to form the nitrate. This is in beautiful white, nearly opaque, tetrahedral or octohedral crystals, which are permanent in the air, of a sweet astringent taste, soluble in seven and a half parts of water, and in alcohol, and composed of one eq. of acid 54, and one of protoxide 111·6=165·6, without water of crystallization.

The following characteristics are given in the U. S. Pharmacopœia. "Its solution is precipitated black by sulphohydrate of ammonia, white by ferrocyanuret of potassium, and yellow by iodide of potassium. When nitrate of lead is triturated with sulphuric acid, the mixture colours morphia red, and if heated evolves nitrous fumes."

Medical Properties, &c. The effects of this salt upon the system are the same as those of the other soluble salts of lead; but, though formerly employed, it is now quite out of use as an internal remedy. Externally it is occasionally applied to excoriated surfaces; and a solution made in the proportion of ten grains to an ounce of water, and coloured probably with alkanet, has been used on the continent of Europe, as a secret remedy, in sore nipples, chopped hands, cracked lips, &c. It has recently been found useful in the correction of fetid odours dependent on the presence of sulphuretted hydrogen or hydrosulphate of ammonia, which it decomposes. It is employed for this purpose in solution, which may be sprinkled in apartments, or applied to putrescent ulcers, or mixed with offensive discharges, the odour of which it is desirable to correct. It will not prevent the putrefaction of animal substances; and there is no reason to suppose that it is capable of rendering contagious or marsh miasms innoxious. *Ledoyen's disinfecting fluid* is a solution of nitrate of lead in the proportion of a drachm to an ounce. Should the salt be used internally, the dose would be from the fourth to the half of a grain.

Dr. Ogier Ward has found a solution extremely useful as an injection and lotion in cases of fetid discharges from the uterus and vagina, in gleety discharges from the urethra, in sloughing and indolent ulcers, and in chronic impetiginous affections of the skin. He prepares the solution extemporaneously by dissolving a scruple of carbonate of lead in sufficient diluted nitric acid for solution, and adding a pint of distilled water. The application is to be made twice or three times daily. (*Prov. Med. and Surg. Journ.*, Oct. 15, 1851.)

Off. Prep. Plumbi Iodidum. W.

PLUMBI OXIDUM RUBRUM. *Ed.*

Red Oxide of Lead.

Red lead, Minium; Deutoxide de plomb, Oxide rouge de plomb, Minium, *Fr.;* Mennig, *Germ.;* Minio, *Ital., Span.*

Preparation. Red lead is prepared on the large scale in a furnace, with the floor slightly concave and the roof arched, presenting a general resemblance to a baker's oven. The lead is placed on the floor, and gradually raised to a red heat, whereby it melts and becomes covered with a pellicle of protoxide, which is removed by means of a long iron scraper; and the pellicles, as they successively form, are scraped off, until the whole of the metal has been converted into them. The product is subjected to further calcination with occasional stirring, for some time, with a view to oxidize any particles of metallic lead. It is thus rendered yellow, and constitutes the *protoxide of lead* or *massicot*. This is taken out of the furnace and thrown upon a level pavement, and cooled by being sprinkled with water. It is next reduced to fine powder by trituration and levigation, and dried; and in this state is introduced into large, shallow, square tin boxes, which are placed in another furnace, closed from the air, and heated nearly to redness; the heat being allowed gradually to fall during a period of from twenty-four to thirty hours. At the end of this time the protoxide of lead will have combined with an additional quantity of oxygen, and become the red oxide. This is taken out, and having been passed through a fine wire sieve, is packed in barrels for the purposes of commerce.

The above is an outline of the French process for making red lead. In England and the United States, the calcination of the protoxide is not performed in tin boxes, but by returning it to the furnace in which it was first calcined. To save the first calcination, litharge is generally used for making the red lead of commerce, which consequently is liable to contain the impurities of that substance, consisting of iron, copper, a little silver, and silica. Copper is hurtful in red lead when used for making glass, to which it communicates colour. In order to have red lead of good quality, it should be made in large quantities at a time. It is also important that it be slowly cooled; for, as the absorption of oxygen by which it is formed takes place during a particular interval of temperature only, it is necessary that the heat within that interval should be maintained sufficiently long to allow all the protoxide to absorb its appropriate dose of oxygen.

Properties, &c. Red lead is in the form of a heavy, scaly powder, of a bright red colour, with a slight shade of orange. Its sp. gr. is about 9. When exposed to heat it gives off oxygen, and is reduced to the state of protoxide. It is sometimes adulterated with red oxide of iron, or red bole, substances which may be detected by treating the red lead with nitric acid, and testing the nitric solution with tincture of galls. This reagent will produce a black precipitate, in consequence of the iron being dissolved by the nitric acid. If brick-dust be present, it will be left undissolved upon boiling the suspected specimen in water, with sugar and a small quantity of nitric acid. When free from impurities, it is completely reduced on charcoal, by means of the blowpipe, into a globule of metallic lead. It is completely soluble in highly fuming nitrous acid. (*Ed. Pharm.*) When treated with nitric acid, it is resolved into protoxide which dissolves, and deutoxide which remains in the form of a dark-brown powder.

The red lead of commerce may be considered as a mixture of what may be called the true red oxide, and variable proportions of protoxide. That this is its nature is proved by the action of cold dilute acetic acid, not used in excess, which takes up a variable quantity of protoxide, leaving a portion unchanged in colour, which may be deemed the pure red oxide. This latter, when analyzed by nitric acid, has been proved, by the coincident results of Dalton, Dumas, and Phillips, to consist of three eqs. of lead, and four of oxygen, equal to $2PbO,PbO_2$ (Dumas), or PbO,Pb_2O_3 (Winckelblech). According to Mulder, red lead has usually the following composition: $Pb_4O_5=3PbO,PbO_2$, or $2PbO,Pb_2O_3$. (*Chem. Gaz.*, Jan. 15, 1851.)

Red lead enters into no officinal preparation. It is employed by the Edinburgh College in preparing *Acidum Aceticum* and *Chlorinei Aqua*. In the arts it is used chiefly as a paint, and as an ingredient of flint glass. B.

PLUMBI OXIDUM SEMIVITREUM. *U. S.*

Semivitrified Oxide of Lead.

Off. Syn. PLUMBI OXIDUM. Plumbi Oxidum *semivitreum. Lond.* LITHARGYRUM. *Ed., Dub.*

Litharge; Oxide de plomb fondu, Litharge, *Fr.;* Bleiglatte, *Germ.;* Litargirio, *Ital.;* Almartaga, *Span.*

When the protoxide of lead is rendered semi-crystalline by incomplete fusion, it becomes the semivitrified oxide, or litharge. Almost all the litharge of commerce is obtained, as a secondary product, in the process for extracting silver from argentiferous galenas. After extracting the argentiferous lead from the ore, the alloy is calcined in the open air; whereby the lead becomes oxidized, and by fusion passes into the state of litharge, while the silver remains unchanged. The following is an outline of the process. The lead containing the silver is placed

upon an oval slightly excavated dish, about three feet long and twenty inches wide, called a *test*, made by beating pulverized bone-ash, made into a paste with water, into a mould, the sides of which are formed of an elliptical band of iron, and the bottom of strips of sheet iron, placed at short distances apart. The test is of such a size as exactly to fit an opening in the floor of a reverberatory furnace, where it is placed and adjusted to the level of the floor. On one side of the test the fire-place is situated, and exactly opposite, the chimney; while at one extremity of it the pipe of a strong bellows is placed, and at the other a vertical hole is made, communicating with a gutter leading from the centre of the test. The furnace is now lighted, and shortly afterwards the bellows is put in motion. The lead fuses and combines with oxygen, and the resulting oxide, melting also, forms a stratum which swims on the surface, and which is driven by the blast of the bellows, along the gutter and through the vertical hole, into a recipient below, where, upon solidifying, it crystallizes in small scales, which form the litharge. In proportion as the lead is oxidized and blown off the test, fresh portions are added, so as to keep it always sufficiently full. The process is continued for eight or ten days, after which no more lead is added. The operation is now confined to the metal remaining on the test; and, the oxidation proceeding, a period at last arrives when the whole of the lead has run off as litharge, and the silver, known to be pure by its brilliant appearance in the fused state, alone remains. This is then removed, and the process repeated on a fresh portion of argentiferous lead.

Properties. Litharge is in the form of small, brilliant, vitrified scales, some presenting a red, and others a yellow colour. In mass it has a foliaceous structure. It is devoid of taste or smell. It slowly attracts carbonic acid from the air, and contains more of this acid the longer it has been prepared. It is on this account that it commonly effervesces slightly with the dilute acids. It has the property of decolorizing wines, when agitated with them. When heated with the fats and oils, in connexion with water, it saponifies them. (See *Emplastrum Plumbi.*) In dilute nitric acid it should be almost entirely soluble. As it occurs in commerce, it usually contains iron, copper, and a little silver and silica. The English litharge is most esteemed; that from Germany being generally contaminated with iron and copper. In choosing litharge, samples should be selected which are free from copper, and from fragments of vegetable matter. Copper is detected, if, upon adding ferrocyanuret of potassium to a nitric solution of the litharge, a brown instead of a white precipitate is produced. Two varieties of litharge are distinguished in commerce, named from their colour, and dependent on differences in the process for making it. Sometimes it has a pale yellow colour and silvery appearance, and is then denominated *silver litharge* or *yellow litharge;* at other times it is of a red colour, and is known under the name of *gold litharge* or *red litharge.* The latter has been said to owe its colour to the presence of a portion of red lead; but M. Leblanc has shown that the two varieties of litharge differ in colour, structure, and density only, and not in chemical composition. In composition, litharge is essentially identical with the protoxide of lead. (See *Plumbum.*) The carbonic acid which it contains is variable; but its average amount is about four per cent.

Pharmaceutical Uses, &c. Litharge is never used internally, but is employed in several pharmaceutical operations, and forms an ingredient in various external applications, used for abating inflammation, and for other purposes. By reaction with olive oil it forms the *Emplastrum Plumbi*, which is the basis of many of the *Plasters.* (See *Emplastra.*) In the arts it is employed in the glazing of pottery, in painting to render oils drying, and as an ingredient in flint glass.

PODOPHYLLUM. *U. S.*

May-apple.

The rhizoma of Podophyllum peltatum. *U. S.*

Podophyllum. *Sex. Syst.* Polyandria Monogynia.—*Nat. Ord.* Ranunculi, *Juss.*; Podophylleæ, *Lindley.*

Gen. Ch. Calyx three-leaved. *Corolla* nine-petalled. *Berry* one-celled, crowned with the stigma. *Willd.*

Podophyllum peltatum. Willd. *Sp. Plant.* ii. 1141; Barton, *Med. Bot.* ii. 9; Carson, *Illust. of Med. Bot.* i. 18, pl. 11. The may-apple, known also by the name of *mandrake*, is an indigenous herbaceous plant, and the only species of the genus. The root (rhizoma) is perennial, creeping, usually several feet in length, about one-quarter of an inch thick, of a brown colour externally, smooth, jointed, and furnished with radicles at the joints. The stem is about a foot high, erect, round, smooth, divided at top into two petioles, and supporting at the fork a solitary one-flowered peduncle. Each petiole bears a large, peltate, palmate leaf, with six or seven wedge-shaped lobes, irregularly incised at the extremity, yellowish-green on their upper surface, paler and slightly pubescent beneath. The flower is nodding. The calyx is composed of three oval, obtuse, concave, deciduous leaves. The corolla has from six to nine white, fragrant petals, which are obovate, obtuse, concave, with delicate transparent veins. The stamens are from thirteen to twenty, shorter than the petals, with oblong, yellow anthers, of twice the length of the filaments. The stigma is sessile, and rendered irregular on its surface by numerous folds or convolutions. The fruit is a large oval berry, crowned with the persistent stigma, and containing a sweetish fleshy pulp, in which about twelve ovate seeds are embedded. It is, when ripe, of a lemon-yellow colour, diversified by round brownish spots.

The plant is extensively diffused throughout the United States, growing luxuriantly in moist shady woods, and in low marshy grounds. It is propagated by its creeping root, and is often found in large patches. The flowers appear about the end of May and beginning of June; and the fruit ripens in the latter part of September. The leaves are said to be poisonous. The fruit has a subacid, sweetish, peculiar taste, agreeable to some palates, and may be eaten freely with impunity. From its colour and shape, it is sometimes called *wild lemon*. The root is the officinal portion, and is said to be most efficient when collected after the falling of the leaves. It shrinks considerably in drying.

Properties. The dried root is in pieces about two lines in thickness, with swelling, broad, flattened joints at short intervals. It is much wrinkled lengthwise, is yellowish or reddish-brown externally, and furnished with fibres of a similar, but somewhat paler colour. The fracture is short and irregular, and the internal colour whitish. The powder is light yellowish-gray, resembling that of jalap. The root in its aggregate state is nearly inodorous; but in powder has a sweetish not unpleasant smell. The taste is at first sweetish, afterwards bitter, nauseous, and slightly acrid. Both the decoction and tincture are bitter; but alcohol is said to be the best solvent of the active matter. A bitter substance was extracted from the root by William Hodgson, jun., of Philadelphia, by boiling it with quicklime in water, straining the decoction, precipitating the lime with sulphate of zinc, evaporating the clear solution to the consistence of an extract, treating this with cold alcohol of 0·817, filtering and evaporating the alcoholic solution, and treating the residue with boiling distilled water, which deposited the substance referred to on cooling. (*Journ. of the Phil. Col. of Pharm.*, iii. 273.) Though the alcoholic solution of this substance is very bitter,

it has upon trial been found not to be the purgative principle of the root. Analyzed by Mr. John R. Lewis, podophyllum yielded albumen, gum, starch, extractive, lignin, gallic acid, fixed oil, traces of volatile oil, salts of potassa and lime, and two resinous principles, one soluble in alcohol and ether, and the other soluble in alcohol only. Both resins were found to possess the active properties of the root. Six grains operated as a drastic cathartic, with some emetic effect. (*Am. Journ. of Pharm.*, xix. 165.) Dr. Manlius Smith recommends that the resin should be prepared by forming an alcoholic tincture of the root, evaporating the tincture till most of the alcohol is driven off, and throwing the residue into water, by which the resin is precipitated. The concentration should not be carried too far; as otherwise the resin separates in clots, which cannot be easily washed. According to Dr. Smith, the resin, when pure, is white, and purges actively in the dose of two or three grains. It is called by some *podophyllin*. (*Ibid.*, xxiv. 306.)

Medical Properties and Uses. Podophyllum is an active and certain cathartic, producing copious liquid discharges without much griping, or other unpleasant effect. In some cases it has given rise to nausea and even vomiting, but the same result is occasionally experienced from every active cathartic. Its operation resembles that of jalap; but is rather slower, and is thought by some to be more drastic. It is applicable to most inflammatory affections which require brisk purging; and is much employed in various parts of the country, especially combined with calomel, in bilious fevers and hepatic congestions. It is also frequently used in connexion with bitartrate of potassa in dropsical, rheumatic, and scrofulous complaints.

The dose of the powdered root is about twenty grains. An extract is prepared from it possessing all its virtues in a smaller bulk. (See *Extractum Podophylli.*) In minute doses, frequently repeated, podophyllum is said to diminish the frequency of the pulse, and to relieve cough; and for these effects is sometimes used in hæmoptysis, catarrh, and other pulmonary affections.

Off. Prep. Extractum Podophylli. W.

POLYGALA RUBELLA. *U. S. Secondary.*

Bitter Polygala.

The root and herb of Polygala rubella. *U. S.*

Polygala. See SENEGA.

Polygala rubella. Willd. *Sp. Plant.* iii. 875; Bigelow, *Am. Med. Bot.* iii. 129.—*P. polygama.* Walter, *Flor. Car.* 179; Pursh, *Flor. Am. Sept.* 465. This species of Polygala is an indigenous, perennial plant, with a branching, somewhat fusiform root, which sends up annually numerous simple, smooth, and angular stems, from four to eight inches in height. The leaves are scattered, sessile, obovate or linear-lanceolate, attenuated towards the base, obtuse, and mucronate. The flowers are purple, and in elongated terminal racemes. From the base of the stem proceed other racemes, which lie upon the ground, or are partially buried under it, and bear incomplete but fertile flowers, the calyx of which is without wings.

This plant is found in many parts of the United States, preferring a dry sandy or gravelly soil, and flowering in June and July. The whole plant is officinal. It has a strong and permanent bitter taste, which it yields to water and alcohol.

Medical Properties and Uses. In small doses bitter polygala is tonic, in larger, laxative and diaphoretic. The infusion of the dried plant has been usually employed to impart tone to the digestive organs. (*Bigelow.*) It appears to be closely analogous in medical virtues to the *Polygala amara* of Europe, which is used for a similar purpose. W.

POTASSIUM.

Potassium.

Potassium, *Fr.;* Kalium, Kalimetall, *Germ.:* Potassio, *Ital.;* Potasio, *Span.*

Potassium is a peculiar metal, forming the radical of a number of important medicinal preparations. It was discovered in 1807 by Sir H. Davy, who obtained it by decomposing hydrate of potassa by galvanic electricity. It was afterwards procured in larger quantity by Gay-Lussac and Thenard, by bringing the fused alkali in contact with white-hot iron, which attracted the oxygen and set free the metal. The best process is that of Brunner, as modified by Wöhler, which consists in decomposing potassa in the state of carbonate, mixed with charcoal. The mixture of carbonate and charcoal is obtained by heating cream of tartar to redness in a covered crucible. For an account of some improvements in Brunner's process by MM. Mareska and Donny, see *Am. Journ. of Pharm.*, xxv. 70.

Potassium is solid, softer and more ductile than wax, easily cut with a knife, and of a silver-white colour. A newly cut surface is brilliant; but the metal quickly tarnishes by combining with the oxygen of the air, and assumes the appearance of lead. It possesses a remarkably strong affinity for oxygen, and is capable of taking that element from every other substance. On account of this property it must be kept in liquids, such as naphtha, which are devoid of oxygen as a constituent. Its sp. gr. is 0·865, its melting point 136°, its equivalent number 39·2, and symbol K. When thrown upon water it swims, takes fire, and burns with a rose-coloured flame, combining with oxygen, and generating potassa which dissolves in the water. It forms numerous combinations, uniting with most of the non-metallic elements, and with several of the metals. It combines in two proportions with oxygen, forming a protoxide (*dry potassa*) of a gray, and a *teroxide* of a yellowish-brown colour. It also unites with chlorine, and forms officinal compounds with iodine, bromine, sulphur, cyanogen, and ferrocyanogen, under the names of iodide, bromide, sulphuret, cyanuret, and ferrocyanuret of potassium. Its protoxide (dry potassa) is a strong salifiable base, existing in nature always in combination, and forming with acids a numerous and important class of salts. Of these, the acetate, bichromate, carbonate, bicarbonate, chlorate, citrate, hydrate (caustic potassa), nitrate, sulphate, sulphuretted sulphate, bisulphate, tartrate, and bitartrate are officinal, and will be described under their respective titles, to which, for their properties, the reader is referred. B.

POTASSÆ BICHROMAS. *Dub.*

Bichromate of Potassa.

Red chromate of potassa; Kali chromicum rubrum, *Lat.;* Bichrômate de potasse, *Fr.;* Zweifach chromsaures kali, *Germ.*

This salt is most conveniently prepared from the neutral or yellow chromate of potassa, by acidulating its solution with sulphuric acid, and setting it aside for a day or two. The acid withdraws one eq. of potassa from two of the neutral chromate, thus generating one eq. of the bichromate, which separates in orange-red crystals. The yellow chromate is obtained by igniting four parts of powdered chrome-iron ore (FeO,Cr_2O_3) with one part of nitre, and lixiviating the resulting mass with water. The solution, by evaporation, yields the yellow salt in crystals. In this process, the nitric acid of the nitre furnishes oxygen to convert the sesquioxide of chromium into chromic acid, which then unites with the potassa of the same salt. The iron, in the mean time, is sesquioxidized and

rendered insoluble. Sometimes impure carbonate of potassa (pearlash) is substituted for part of the nitre in the calcination. It is said that, recently, lime has been used with economical results, instead of the nitre and pearlash, in performing the ignition. When lime is employed, chromate of lime is formed, which is extracted by lixiviation, and decomposed by a soluble salt of potassa. When desired, the bichromate may be obtained directly from the solution of chromate of potassa, derived from the treatment of the ore, by acidulating it with sulphuric acid, without first crystallizing it.

Bichromate of potassa is in the form of orange-red, anhydrous, prismatic crystals, soluble in ten parts of cold and much less boiling water, but insoluble in alcohol. Its taste is cooling and bitter. Exposed to a red heat, it fuses, without decomposition, into a red liquid, which congeals on cooling into a crystalline mass, and then falls to powder. It consists of two eqs. of chromic acid and one of potassa, and its formula is $KO,2CrO_3$.

Medical Properties, &c. Bichromate of potassa, in small doses, is alterative, in larger emetic. Externally it acts as an irritant and caustic. It was first used internally, in 1850, by M. Robin, who gave it in secondary syphilis; and Prof. Heyfelder, of Erlangen, afterwards employed it in the same disease with encouraging results. It acts like the mercurials on the syphilitic poison, but without producing salivation. It was recommended, in 1827, by Dr. Cumin, in saturated solution, as a caustic application to tubercular elevations, excrescences and warts, and more recently (1850) by M. Puche in syphilitic vegetations. It causes the morbid parts to shrivel and fall off. The dose as an alterative is one-fifth of a grain daily, in the form of pill made with extract of gentian, to be increased gradually to five or six pills a day. As an emetic the dose is three quarters of a grain. It may be used as a caustic in the form of powder.

Bichromate of potassa is an energetic poison. When the stomach does not relieve itself by vomiting, bicarbonate of soda, magnesia, or a solution of soap should be immediately given as an antidote.

Bichromate of potassa is manufactured largely for the use of calico-printers. The workmen engaged in making it are liable to painful ulcerations of the hands. It was introduced into the Dublin Pharmacopœia of 1850, not as a therapeutic agent, but to be used in forming artificial valerianic acid by reacting with fusel oil (*Alcohol Amylicum*), as a step in the process for preparing valerianate of soda. (See *Sodæ Valerianas.*) B.

POTASSÆ BITARTRAS. *U. S., Lond., Ed., Dub.*

Bitartrate of Potassa.

Supertartrate of potassa, Crystals of tartar, Cream of tartar; Cremor tartari, *Lat.;* Tartrate acide de potasse, Crème de tartre, *Fr.;* Doppelt weinsaures Kali, Weinsteinrahm, *Germ.;* Cremore di tartaro, *Ital.;* Cremor de tartaro, *Span.*

During the fermentation of wines, especially those that are tart, a peculiar matter is deposited on the bottom and sides of the casks, forming a crystalline crust, called *crude tartar* or *argol.* That deposited from red wines is of a reddish colour, and called in commerce *red tartar;* while that derived from white wines is of a dirty white colour, and denominated *white tartar.* Both kinds consist of potassa, united with an excess of tartaric acid, forming bitartrate of potassa, rendered impure by tartrate of lime, more or less colouring matter, and the lees and other matters which are deposited during the clarification of the wine. The deposition of the tartar is thus explained. The bitartrate exists naturally in the juice of the grape, held in solution by saccharine matter. When the juice is submitted to fermentation in the process for converting it into wine, the sugar disappears, and is replaced by alcohol, which, not being competent to

dissolve the salt, allows it to precipitate as a crystalline crust. It is from this substance that bitartrate of potassa is obtained by a process of purification.

The process is conducted on a large scale at Montpellier, in France, and is founded upon the greater solubility of bitartrate of potassa in hot than in cold water. The tartar, previously pulverized, is boiled with water in copper boilers. The solution, when saturated, is transferred to earthen pans, where it deposits on cooling a crystalline layer, nearly free from colour. This is redissolved in boiling water; and the solution, having been mixed with four or five per cent. of pipe-clay, is evaporated to a pellicle. The clay precipitates with the colouring matter, and the clear solution, as it cools, deposits white crystals in crusts, which, upon being exposed to the air on linen for several days, acquire an increased degree of whiteness. These constitute the *crystals of tartar* of pharmacy. The salt, however, as met with in the shops, is generally, for greater convenience, in the form of powder, to which the name of *cream of tartar* is properly applied.

Properties. Bitartrate of potassa occurs in commerce in white crystalline crusts, or masses of aggregated crystals, and is received in that state from France by our wholesale druggists, who procure its pulverization for the use of the apothecaries. In crystals it is hard and gritty between the teeth, and dissolves slowly in the mouth; in powder it has a white colour. It is a permanent salt, of an acid not ungrateful taste, and acid reaction, soluble in 184 parts of cold, and 18 of boiling water, but insoluble in alcohol. When exposed to a red heat it is decomposed, exhales a peculiar odour, gives rise to a solid pyrogenous acid, and the usual products of the destructive distillation of vegetable matter; and carbonate of potassa, mixed with charcoal, is left. Its solution is precipitated by solutions of baryta, strontia, and lime, which form insoluble tartrates, and by acetate of lead, forming tartrate of lead. With salifiable bases which form soluble tartrates, it gives rise to double salts, consisting of neutral tartrate of potassa, and the tartrate of the base added. Several of them are important medicines, and will be described under their respective titles. Cream of tartar, though sparingly soluble in water, becomes abundantly so by the addition of borax or boracic acid. (See *Sodæ Boras.*)

The cream of tartar of commerce is not a pure bitartrate of potassa. It usually contains from two to five per cent. of tartrate of lime, which should not be viewed as an adulteration. But it is said to be purposely mixed with various substances, among which are sand, clay, gypsum, flour, chalk, alum, and sulphate of potassa. Sand, clay, and gypsum may be detected by their insolubility in a hot solution of potassa; flour, by striking a blue colour with iodine; chalk, by its effervescing with dilute acids; alum, an unlikely sophistication, probably by its astringent taste; and any soluble sulphate, by a precipitate being produced by chloride of barium, not entirely soluble in nitric acid. The action of the last mentioned test is explained by the fact, that the tartrate of baryta is soluble in nitric acid, but not the sulphate. The best security against fraud is to purchase the crystals, which are not subject to the same adulterations as the powder.

Composition. Cream of tartar consists of two eqs. of tartaric acid 132, one of potassa 47·2, and one of water 9=188·2. The water cannot be expelled without decomposing the salt, and is supposed to act the part of a base.

Medical Properties and Uses. Bitartrate of potassa is cathartic, diuretic, and refrigerant. In small doses it acts as a cooling aperient, in large ones as a hydragogue cathartic, producing copious watery stools; and from this latter property, as well as its tendency to excite the action of the kidneys, it is very much used in dropsical affections. It is frequently prescribed in combination with senna, sulphur, or jalap. (See *Pulvis Jalapæ Compositus.*) Its solution in boiling water, sweetened with sugar and allowed to cool, forms an acid, not unpleasant, refrigerant drink, advantageously used in some febrile affections, and frequently

employed as a domestic remedy. The beverage called *imperial* (*potus imperialis*) is a drink of this kind, made by dissolving half an ounce of the salt in three pints of boiling water, and adding to the solution four ounces of white sugar, and half an ounce of fresh lemon peel. *Cream of tartar whey* is prepared by adding about two drachms of the bitartrate to a pint of milk. It may be given, diluted with water, in dropsical complaints. The dose of cream of tartar is a drachm or two as an aperient; and from half an ounce to an ounce as a hydragogue cathartic, mixed with molasses or suspended in water. As a diuretic in dropsical cases, it may be given in the dose of a drachm and a half or two drachms, several times a day.

In pharmacy, cream of tartar is employed to obtain the neutral tartrate of potassa (soluble tartar), tartrate of potassa and soda (Rochelle salt), tartrate of antimony and potassa (tartar emetic), and tartrate of iron and potassa (tartarized iron). Deflagrated with nitre, or incinerated alone, it is converted into a pure form of carbonate of potassa, called salt of tartar. (See *Potassæ Carbonas Purus.*) In the laboratory it is used to procure potassa in a pure state, and for making black and white flux. *Black flux* is prepared by deflagrating cream of tartar with half its weight of nitre; and *white flux*, by deflagrating it with twice its weight of the same salt.

POTASSÆ CARBONAS IMPURUS. *U. S.*

Impure Carbonate of Potassa.

The impure carbonate of potassa known in commerce by the name of *pearl-ash. U. S.*

Off. Syn. LIXIVUS CINIS. Impure Potash; Pearlash. *Dub.*

Pearlash, Pearlashes, Impure potassa, Impure subcarbonate of potassa; Potasse du commerce, *Fr.;* Rohe Pottasche, *Germ.:* Potasch, *Dutch;* Potaske, *Dan.;* Potaska, *Swed.;* Potassa del commercio, *Ital.;* Cenizas claveladas, *Span.*

The alkali potassa, using this term in its strict sense, is the protoxide of the metal potassium. (See *Potassium.*) It exists in various states of combination and purity. In its most impure state, it is the common potash of commerce. This, subjected to calcination, becomes somewhat purer, and is then called *pearl-ash*, the form of the alkali intended to be designated by the officinal name at the head of this article.

Natural State and Preparation. Potash and pearlash of commerce are procured from the ashes of wood by lixiviation, and the subsequent evaporation of the solution obtained. The alkali exists in the wood, principally in the state of acetate; and, being of a fixed and incombustible nature, is left behind after the incineration. The wood is burnt on the ground, in a place sheltered from the wind. The ashes consist of a soluble and insoluble portion. The soluble part is made up of carbonate of potassa, together with the sulphate, phosphate, and silicate of potassa, and the chlorides of potassium and sodium; the insoluble portion, of carbonate and subphosphate of lime, alumina, silica, oxidized iron and manganese, and a little carbonaceous matter that has escaped combustion. The ashes are lixiviated in barrels with the addition of a portion of lime, and the soluble substances above mentioned are taken up. The lixivium is then evaporated in large iron kettles, which for several days are kept constantly full. The evaporation is continued until the mass has become of a black colour, and of the consistence of brown sugar. It is now subjected to as powerful a heat as can be

raised by the best wood fire for a number of hours, by which it is fused. During the progress of the fusion, the combustible impurities are for the most part burnt out, and a gaseous matter is emitted, which agitates the more fluid part. When the fusion is complete, the liquid becomes quiescent, and looks like melted iron. It is now transferred, by means of large iron ladles, to iron pots, where it congeals in cakes. These are broken up and packed in tight barrels, and constitute the *potash* of commerce. (*Dr. G. A. Rogers*, in Silliman's Journal.)

If it be intended to make *pearlash*, the process is varied. In this case the black matter, above mentioned as of the consistence of brown sugar, called *black salts* by our manufacturers, instead of being fused, is transferred from the kettles to a large oven-shaped furnace, so constructed that the flame may be made to play over the alkaline mass, which in the mean time is stirred by means of an iron rod. The ignition is in this way continued, until the combustible impurities are burnt out, and the mass, from being black, becomes of a dirty bluish-white colour. (*Rogers.*)

The ashes of plants amount generally to not more than a few parts in the hundred; and of these a portion only consists of potassa. The different parts of the same vegetable, and, for a stronger reason, different plants, furnish variable quantities of ashes. Ligneous plants yield less than herbaceous, the trunk less than the branches, and the branches less than the leaves. The bark yields more ashes than the wood; and the leaves of trees which drop their foliage in winter more than the leaves of evergreens. The following table gives the quantity of potassa contained in the ashes of one thousand parts of the undernamed plants:

Pine	0·45	Barley straw	5·8
Poplar	0·75	Beech bark	6·0
Birch	1·29	Fern	6·2
Beech	1·45	Stalks of Indian corn	17·5
Oak	2·03	Sun-flower stalks	19·4
Oak bark	2·08	Dry oak leaves	24·0
Box	2·26	Common nettle	25·0
Willow	2·85	Black elder	25·5
Linden	3·27	Vetch	27·5
Elm	3·9	Poke	45·6
Maple	3·9	Wheat stalks, young	47·0
Wheat straw	4·18	Dried stems of potatoes	55·0
Flax	5·0	Wormwood	73·0
Rush	5·08	Fumitory	79·0
Common thistle	5·37	Angelica	96·2
Vine branches	5·5		

Commercial History. Potash and pearlash are made in those countries in which forests abound. Accordingly, the alkali is extensively manufactured in Canada and the United States, and constitutes a very important export of this country. It is prepared chiefly in the State of New York, which is supposed to furnish three-fourths of our exports of this alkali. It is also produced in considerable quantities in the northern countries of Europe, especially in Russia, and on the shores of the Baltic. It is of different qualities as it occurs in commerce; and is distinguished by the country or place of manufacture, as *American, Russian, Dantzic potash, &c.*

Properties. Potash is in the form of fused masses of a stony appearance and hardness, and caustic burning taste. Its colour is variegated; but reddish and dark-brown are the predominant hues. When exposed to the air it absorbs moisture and deliquesces; and, if sufficiently long exposed, finally becomes liquid. *Pearlash* is of a white colour, with usually a tinge of blue. As it occurs in commerce, it is in tight casks, containing about three hundred and fifty pounds, in which it forms one entire, hard, concrete mass. In the shops it is found in coarse

powder, intermingled with lumps as dug out of the casks, presenting an opaque granular appearance, like table salt or Havana sugar. It is a deliquescent salt, and has a burning alkaline taste. It is soluble in water, with the exception of impurities. The soluble matter in one hundred grains of the salt of medium quality will neutralize about fifty-eight grains of sulphuric acid. It differs from potash principally in containing less combustible impurities, and in being less caustic and deliquescent. The colouring matter of both these forms of alkali is derived from carbonaceous impurities, and small portions of iron and manganese.

Composition. The basis of both pot and pearlash is carbonate of potassa; but this is associated with certain salts, and with insoluble impurities. Several varieties of potash found in commerce were analyzed by Vauquelin, whose principal results are contained in the following table. The quantity examined of each kind was 1152 parts.

Kinds of Potash.	Caustic Hydrate of Potassa.	Sulphate of Potassa.	Chloride of Potassium.	Insoluble Residue.	Carbonic Acid and Water.
American potash . . .	857	154	20	2	119
Russian potash . . .	772	65	5	56	254
Pearlash	754	80	4	6	308
Dantzic potash . . .	603	152	14	79	304

These results, calculated for 100 parts, show that the American potash contains 74 per cent. of pure hydrated alkali, and the Russian 67 per cent. Pearlash, it is seen, is more rich in carbonic acid than potash; and this result of analysis corresponds with the qualities of the two substances as prepared in the United States; potash being known to be far more caustic than pearlash. Besides the impurities shown by the table, silicate of potassa is present. According to Mr. Stevenson Macadam, the potashes of commerce contain iodine and a trace of bromine, which shows that the forest trees from which the alkali is obtained must contain a very minute proportion of these non-metallic elements. (*Chem. Gaz.*, Aug. 2, 1852, p. 284.)

As the potash of commerce is valuable in the arts in proportion to the quantity of real alkali which it contains, it is important, in so variable a substance, to possess an easy method of ascertaining its quality in that respect. The process by which this is accomplished is called *alkalimetry*, and the instrument used an *alkalimeter*. The best mode of proceeding, which is applicable to the commercial forms of soda as well as those of potassa, is that proposed by Faraday, and described by Turner as follows. Take a cylindrical tube, sealed at one end, nine and a half inches long, and three-quarters of an inch in diameter, and pour into it one thousand grains of water, marking with a file the point at which the water stands. Divide the space occupied by the water into one hundred equal parts, graduating from above downwards; and, opposite to the numbers 23·44, 48·96, 54·63, and 65, severally write the words soda, potassa, carbonate of soda, and carbonate of potassa. Then prepare a dilute sulphuric acid having the specific gravity 1·127, which may be formed by adding to the strong acid about four times its volume of distilled water. An acid of this strength, if added to the tube so as to reach to any one of the heights denoted by the above numbers, will be just sufficient to neutralize one hundred grains of the alkali written opposite to it. Suppose, for example, that the dilute acid be added until it stands opposite to the word carbonate of potassa, we shall then have the exact quantity necessary to neutralize one hundred grains of that carbonate; and if we add pure water, until the liquid reaches to 0, or the beginning of the scale, it is evident that the acid has been brought to the bulk of a hundred measures, each of which

would be competent to neutralize one grain of the carbonate in question. All that is now necessary, in order to ascertain the quality of any commercial sample of this carbonate, is to dissolve one hundred grains of it in warm water, filter the solution to remove insoluble impurities, and add by degrees the dilute acid from the tube until the solution is exactly neutralized, as shown by litmus paper. The number of divisions of acid, expended in attaining this point, may be read off from the tube; and for each division one grain of pure carbonate is indicated.

This method of testing the potash of commerce indicates its alkaline strength, assuming this to be dependent solely on potassa; but soda, a cheaper alkali, may be present as an adulteration, and its proportion is important to be known. To solve this problem, M. O. Henry proposes that the saturating power of a given weight should be first determined in relation to sulphuric acid, and afterwards the proportion of carbonate of potassa in an equal weight, by first converting it into an acetate, and then precipitating the potassa by hyperchlorate (oxychlorate) of soda, the reacting salts being in alcoholic solution. The precipitated hyperchlorate of potassa indicates the proportion of carbonate of potassa. The amount of the latter determines how much of the sulphuric acid was expended in saturating the potassa; and the soda is indicated by the amount of this alkali, equivalent to the remainder of the acid. (*Journ. de Pharm.*, vii. 214.) Another method of detecting soda in the potash of commerce, proposed by Pagenstecher, is to convert the suspected alkali into a sulphate, and wash the sulphate formed with a saturated solution of sulphate of potassa. If the whole of the saline matter be sulphate of potassa, the washing will cause no loss of weight; but if part of it be sulphate of soda, this will be washed away, on account of its solubility in a saturated solution of sulphate of potassa. (*Journ. de Pharm.*, Mars, 1848, 239.) Frémy has proposed the metantimoniate of potassa as a test for soda in potash. In applying this test, the potash is converted into a neutral chloride of potassium, and treated with a recent solution of the metantimoniate. If the alkali examined contain two or three per cent. of soda, a precipitate is almost instantly formed. If a less proportion of soda be present, time and agitation will be necessary to effect the precipitation. Frémy states that, by this test, he can detect the half of one per cent. of soda in commercial potash. (*Phil. Mag.*, Oct. 1848, 325.)

Pharmaceutical Uses. Pearlash is never used as a medicine, being considered as too impure. It is directed to be purified in the U. S., Edinburgh, and Dublin Pharmacopœias, in order to form the carbonate of potassa.

Off. Prep. Potassæ Carbonas. B.

POTASSÆ CHLORAS. *U. S.*, *Lond.*, *Dub.*

Chlorate of Potassa.

Hyperoxymuriate of potassa; Chlorate de potasse, *Fr.*; Chlorsaures Kali, *Germ.*

Chlorate of potassa may be prepared by passing an excess of chlorine through a solution of caustic hydrate or carbonate of potassa. At first two eqs. of chlorine react with two eqs. of potassa, so as to form one eq. of chloride of potassium, and one eq. of hypochlorite of potassa ($2Cl$ and $2KO = KCl$ and KO,ClO). Afterwards, by the further action of the chlorine, more chloride of potassium is formed, and the oxygen separated from the potassa converts the hypochlorous acid into the chloric, and consequently the hypochlorite into chlorate of potassa. Thus, $4Cl$, reacting with $4KO$ and KO,ClO, will form $4KCl$ and KO,ClO_5. The chlorate, being but sparingly soluble in water, is separated from the chloride of potassium by priority of crystallization. When carbonate of potassa is used, the carbonic acid is first transferred from a part of the alkali to the remainder, and finally evolved.

Graham has devised an improved process for obtaining this salt. It consists in mixing the carbonate of potassa with an equivalent quantity of hydrate of lime, before submitting it to the action of chlorine. The gas is absorbed with avidity, and the mass becomes hot, while water is given off. The lime converts the carbonate into caustic potassa, and the reaction then takes place between six eqs. of potassa and six of chlorine, with the result of forming five eqs. of chloride of potassium, and one of chlorate of potassa. ($6KO$ and $6Cl = 5KCl$ and KO,ClO_5.) The products are, therefore, carbonate of lime, chloride of potassium, and chlorate of potassa. The chloride and chlorate are separated from the carbonate by solution in hot water, and the chlorate from the chloride by priority of crystallization as before.

In the above process, a large proportion of the potassa is lost by being converted into chloride of potassium. Prof. F. C. Calvert, of Manchester, has almost entirely avoided this loss by his new process, in which he reacts upon one eq. of caustic potassa, mixed with five and a half eqs. of lime, with a stream of chlorine. The potassa is dissolved in sufficient water to form a solution, containing 10¼ per cent. of the alkali (sp. gr. 1·110), and mixed with the lime; and the mixture, after having been gradually heated to 122°, is subjected to a rapid current of chlorine to saturation, the reaction caused by which raises the temperature to about 194°. The product is then evaporated nearly to dryness, the residue dissolved in boiling water, and the solution filtered and set aside to crystallize. The strength of the solution of potassa and the temperature, employed in Prof. Calvert's process, determine the combination of part of the chlorine with calcium, instead of potassium; and the oxygen from the lime converts the remaining chlorine into chloric acid. A higher or lower density of the potassa solution was found not to give as favourable results. This process has been used on a large scale, and is said to have perfectly succeeded. While the old process gives but 43 parts of chlorate to 100 of anhydrous potassa, the new yields 260 parts.

Properties. Chlorate of potassa is a white anhydrous salt, of a cooling and slightly acerb taste. It crystallizes in rhomboidal plates of a pearly lustre. It is soluble in 16 parts of water at 60°, and in two and a half parts of boiling water. When thrown on burning coals, it augments their combustion remarkably. This property is due to the presence of oxygen, which may be evolved from the salt in the proportion of nearly 39 per cent., by heating it a little above its point of fusion. The residue is chloride of potassium.

Chlorate of potassa is characterized by giving out oxygen upon fusion, and leaving a residue of chloride of potassium; by becoming first yellow, and then red by admixture with a little sulphuric acid, and by the action of that acid evolving chlorous acid gas (quadroxide of chlorine), known by its yellow colour, and explosive property when heated; by its bleaching power when mixed first with muriatic acid and then with water; and by its property of exploding violently when triturated with a small portion of sulphur or phosphorus. Its usual impurity is chloride of potassium, which may be detected by a precipitate of chloride of silver being produced on the addition of nitrate of silver. This test does not precipitate the chlorine of the chloric acid. Chlorate of potassa consists of one eq. of chloric acid 75·42, and one of potassa 47·2 = 122·62.

Medical Properties and Uses. Chlorate of potassa is ranked as a refrigerant and diuretic. From experiments made by Dr. O'Shaughnessy and others, it gives a bright scarlet colour to the venous blood, and passes undecomposed into the urine. The first trials made with it as a medicine were founded upon the supposition that it would prove an oxidizing remedy; and hence it was employed in scurvy, which was supposed to depend upon a deficiency of oxygen in the system, and in syphilis and liver complaint as a substitute for mercury, which

mineral was held by some to act in these affections by imparting oxygen. In scurvy it appears to have acted beneficially, but not on the principle which induced its trial; as it would seem not to be decomposed in the system. It has been employed by Dr. Stevens and others as a remedy for certain fevers, and for malignant cholera, to supply a supposed deficiency of saline matter in the blood. Dr. Henry Hunt recommends it strongly in cancrum oris, given in solution, in divided doses, to the amount of from twenty to sixty grains in twenty-four hours, according to the age of the child. It lessens the fetor and salivation attendant on the disease, and promotes the granulation of the sores. (*Braithwaite's Retrospect*, viii. 148.) A similar practice in this disease was followed by Dr. J. H. Babington, of Ireland, with great success. (See *Am. Journ. of Med. Sci.*, April, 1853, p. 491.) Dr. R. L. Scruggs, of Germantown, Tenn., praises its effects, used internally and as a mouth-wash, in the erysipelatous inflammation of the mouth and fauces, which occurs in the disease called *black tongue*. (*Med. Exam.*, April, 1849.) The dose of chlorate of potassa is from ten to thirty grains. The mouth-wash may be made by dissolving a teaspoonful of the salt in four fluid-ounces of water.

Chlorate of potassa is used to obtain pure oxygen; to make matches which take fire by friction, or when dipped in sulphuric acid; and to prepare priming for cannon and fire-arms. B.

POTASSÆ NITRAS. *U. S., Lond., Ed., Dub.*

Nitrate of Potassa.

Nitre, Saltpetre; Nitrate de potasse, Azotate de potasse, Saltpêtre, *Fr.;* Salpetersaures Kali, Salpeter, *Germ., Dutch, Dan., Swed.;* Nitro, *Ital., Span., Port.*

Nitre or saltpetre is both a natural and artificial production. It is found ready formed in many countries, existing in the soil on which it forms a saline efflorescence, in the fissures of calcareous rocks, and in caves. It has been found in different parts of Europe, in Egypt, and in Peru; but the country in which it is most abundantly produced is India, whence the principal part is furnished for the demands of commerce. In the United States it is found, for the most part, in caverns situated in limestone rock, called saltpetre caves, and is associated with nitrate of lime. The earths contained in them are lixiviated, and yield, according to their richness, from one to ten pounds of crude nitre to the bushel. These caves are particularly numerous in Kentucky, and furnished a large proportion of the nitre consumed in the United States during the last war with England. It exists also in the vegetable kingdom, having been found in borage, tobacco, bugloss, parietaria, hemlock, and the sun-flower. The artificial sources of nitre are certain mixtures of animal and vegetable substances with wood-ashes and calcareous matter, called nitre-beds; and certain materials, impregnated with saltpetre, consisting principally of plaster rubbish, derived from the demolition of old buildings.

Preparation from its Natural Sources. In India the saline earth, which on an average contains seven parts of nitre in a thousand, is lixiviated in large mud filters, lined with stiff clay, and furnished with false bottoms of bamboo, covered with grass mats, on which wood-ashes are laid. The filters being then filled with the saline earth, water is added, and the solution filters through the wood-ashes, with the effect of converting any nitrate of lime present, which amounts to nearly one per cent., into nitrate of potassa. The solution obtained is evaporated in earthen pots, filtered, and set aside to crystallize. The impure nitre thus obtained contains from 45 to 70 per cent. of the pure salt. It is redissolved and crystallized by the native merchants, and thrown into commerce under the name of crude nitre, or crude saltpetre.

Artificial Preparation. The plan of forming saltpetre in artificial nitre-beds is principally practised in Germany; while the method of obtaining it from old plaster rubbish is followed in France. *Artificial nitre-beds* are formed of animal and vegetable remains, together with ashes and calcareous earth, which are mixed up with a portion of loose soil and placed under sheds, to shelter the mixture from the rain; while the sides are left open to permit the free access of air. The mixture is disposed in little ranges or heaps, which are frequently turned over with a spade, and sprinkled with urine, as a substance containing a large quantity of nitrogen. At the end of two or three years the nitrogen is converted into nitric acid, and this, by uniting with the potassa existing in the vegetable remains, forms nitre. When the contents of the bed contain about four ounces of the salt for every cubic foot of the materials, they are deemed fit to be lixiviated. The lixiviation is performed with boiling water, which is repeatedly thrown upon fresh portions of the mass, until the solution obtained is sufficiently strong. The lixivium is of a brown colour, and contains chiefly the nitrate of potassa; but at the same time more or less of the nitrates of lime and magnesia, and of common salt. The earthy nitrates are then decomposed by a solution of wood-ashes, the potassa of which converts them into nitre, and precipitates the earths. The solution being further evaporated, the common salt rises to the surface as a scum, and is removed. The solution is then allowed to cool, and the nitrate crystallizes in dirty white crystals, called crude nitre.

Nitrate of lime may be converted into nitre by adding it to a solution of sulphate of potassa. Sulphate of lime is precipitated, and nitrate of potassa remains in solution.

When obtained from old plaster rubbish, the material is reduced to powder and lixiviated, in order to exhaust it of everything soluble. The solution is found to contain the nitrates of potassa and lime, and common salt, and is treated with wood-ashes, which convert the nitrate of lime into nitrate of potassa, with precipitation of the earth as a carbonate. The liquor is separated from the precipitate and concentrated by heat; and the common salt, as it rises to the surface, is skimmed off. When the solution is so strong as to mark 45° of Baumé's areometer, it is allowed to cool and crystallize; and the crystals form the crude nitre of this process. The salt obtained in this way generally contains from 85 to 88 per cent. of pure nitre; the remainder being made up of chloride of sodium, and certain deliquescent salts. The details of this process, as practised in Paris, are given by Thenard.

The artificial preparation of saltpetre is carried on to a considerable extent in Hungary. Prof. Szabo, of Pesth, describes three kinds:—*gay saltpetre*, obtained by washing the earth, dug from the earth floors of the huts of the poorer classes; *plantation saltpetre*, generated in uncovered heaps, composed of two-thirds washed gay earth, and one-third ashes; and *kehr saltpetre*, which is formed, in certain districts, in the surface soil, prepared by strewing it, from time to time, with ashes. (*Chem. Gaz.*, Feb. 2, 1852, p. 47.)

Theory of Nitrification. It is now generally admitted that the continuous formation of nitre in nitre earths, and in artificial nitre-beds, depends upon the oxidation of the nitrogen of ammonia, thus generating nitric acid, the formation of which is facilitated by the presence of alkaline and earthy bases, with which the acid unites. The ammonia is derived, for the most part, from the organic remains in the nitre earths, and from the animal matter which is an essential ingredient in the artificial mixtures.

Purification. Nitrate of potassa, as first obtained, either from natural or artificial sources, is called in commerce crude saltpetre, and requires to be purified or refined before it can be used in medicine, or in most of the arts. The process, which is founded principally on the fact that nitre is more soluble than

common salt in hot water, is conducted in the following manner in France. Thirty parts of the saltpetre are boiled with six parts of water, and the portion which remains undissolved, or is deposited, consisting of common salt, is carefully removed. As the ebullition proceeds, a little water is added from time to time, to hold the nitre in solution. When common salt ceases to be separated, the solution is clarified with glue, and more water is added at intervals, until the whole amounts, including that previously added, to ten parts. The clear solution is now transferred to large, shallow copper coolers, where it is agitated with wooden instruments to hasten the cooling, and to cause the nitre to crystallize in small grains. The purification is completed by washing the salt with water, or a saturated solution of nitre, in a kind of wooden hopper, with holes in the bottom stopped with pegs. The liquid employed is allowed to remain in contact with the nitre for several hours, at the end of which time it is permitted to drain off by taking out the pegs. The salt being now dried, its purification is completed.

In Sweden, the process of purification is conducted in a different manner. The solution of the crude nitre is boiled, until a saline crust (common salt) forms on its surface, and until it is so far concentrated that a small portion of it crystallizes upon cooling. The crust being removed, the solution is filtered, and diluted with 1-48th of water, with a view to retain in solution the common salt, which, being somewhat less soluble in cold than in boiling water, would otherwise be in part precipitated on refrigeration. The solution is now allowed to cool, and, at the moment crystals begin to form, is stirred constantly to cause the salt to crystallize in small grains. The granular salt is then washed after the French method, as above described, dried, and, being fused, is cast in sheet iron moulds so as to form masses, each weighing from ten to twenty pounds. The preparation of nitre in this manner by fusion is, according to Berzelius, attended with several advantages; such as its occupying less space, its losing nothing by waste in transportation, and its presenting, in this state, an obvious index of its quality. This index is the character of its fracture. When the salt is perfectly pure, the fracture is radiated, the radii being generally large. The presence of 1-80th of common salt renders the radii smaller; and of 1-40th, or a larger quantity, produces a zone in the substance of the mass, devoid of the radiated structure, or causes this structure to disappear entirely. On the other hand, the process by fusion has the disadvantage of converting the salt in part into hyponitrite, when heated too high, and of rendering it difficult to pulverize.

Commercial History. Nitre is received in this country from Calcutta in the state of crude saltpetre, packed in grass cloth bags, containing from one hundred and fifty to one hundred and seventy-five pounds. The greater portion of it arrives in Boston. Its quality varies considerably. That which comes in dirty yellow crystals is called *crude saltpetre;* while the finer lots, in small, comparatively clear crystals, approaching to white, are called *East India refined.* Very little crude saltpetre is at present obtained from native sources in the United States, on account of the low price of that from India. The *refined saltpetre* is almost exclusively prepared by our own chemists; and a considerable portion of it is exported.

As connected with the subject of saltpetre, it may be proper in this place to notice what is incorrectly called *South American saltpetre*, considerable quantities of which have been received within a few years from Peru and Chili. It is *nitrate of soda*, and comes in bags containing about two hundred and seventy pounds of the salt in the crude state. This nitrate is coming into use with our manufacturing chemists, and is better suited than nitre for preparing nitric and sulphuric acids, on account of the greater proportional quantity of acid which it contains. It is, however, not applicable to the purpose of making gunpowder, from its tendency to absorb moisture.

Nitrate of soda may be decomposed, so as to yield nitre, by means of *caustic* American potash (red potash of commerce), by Mr. Rotch's patented process. This process gives a nitre equal in purity to the East India refined. For the details see the *Pharm. Journ. and Trans.*, xi. 36. The same salt will furnish nitre by double decomposition with carbonate of potassa (pearlash). (*Ibid.*, xi. 236, from *Pharm. Cent. Blatt.*) Mr. Hill decomposes nitrate of soda by means of chloride of potassium, forming, by double decomposition, nitrate of potassa and chloride of sodium. The latter is got rid of, in the usual manner, by the evaporation of the solution of the mixed salts.

Properties. Nitre is a white salt, possessing a sharp, cooling, and slightly bitterish taste, and generally crystallized in long, striated, semi-transparent, six-sided prisms, with dihedral summits. It dissolves in four or five times its weight of cold, and in about two-fifths of its weight of boiling water. It is sparingly soluble in rectified spirit, but insoluble in absolute alcohol. It undergoes no alteration in the air, unless this be very moist. It yields a yellow precipitate with chloride of platinum, showing that potassa forms its base. It contains no water of crystallization; but is apt to hold a portion of liquid, mechanically lodged within the substance of the crystals. This is particularly the case with the *large* crystals, and, according to Berzelius, is a source of impurity; as the liquid in question is a portion of the mother-waters in which they were formed. It is on this account that Berzelius recommends that the solution of the purified salt should be stirred during crystallization, so as to cause it to shoot into *small* crystals. When exposed to heat, nitre fuses without losing weight at about 662°. The fused mass, when cast in moulds, or formed into little circular cakes, constitutes that form of nitre, kept in the shops under the name of *crystal mineral* or *sal prunelle.** If the heat be increased, the salt is decomposed, evolves pure oxygen, and is reduced to the state of hyponitrite, which, when rubbed to powder, emits orange-coloured fumes of nitrous acid and nitric oxide, on the addition of sulphuric acid. Upon a further continuance of the heat, the hyponitrous acid itself is decomposed, and a large additional quantity of oxygen is evolved, contaminated, however, with more or less nitrogen. On account of the large proportion of oxygen which it contains, nitre increases the combustion of many substances in a remarkable degree. When thrown on burning coals, it deflagrates with bright scintillations. Nitre may be readily recognised by its effect in increasing the combustion of live coals, when thrown upon them; and by evolving white or reddish vapours on the addition of sulphuric acid. Its most usual impurity is common salt, which is seldom entirely absent, and which injures it for the manufacture of gunpowder. The presence of this salt or of chloride of potassium will cause a precipitate with nitrate of silver. If a sulphate be present, a precipitate will be formed with chloride of barium. One hundred grains of the pure and dry salt, treated with sixty grains of sulphuric acid, and the whole ignited until it ceases to lose weight, yield eighty-six grains of sulphate of potassa. If the residue weighs less, part of it is probably sulphate of soda, and the nitre tested may be assumed to have contained nitrate of soda. The refined or purified saltpetre of commerce is sufficiently pure for medical use. Nevertheless, the Dublin College, with needless refinement, has given a formula for its purification. (See *Potassæ Nitras Purum.*) Nitrate of potassa is composed of one eq. of nitric acid 54, and one of potassa 47·2=101·2.

* *Sal prunelle*, as directed to be made in the French Codex, is a mixture of nitrate and sulphate of potassa. It is prepared by fusing nitre in a Hessian crucible, adding 1-128th part of sulphur, and pouring out the product on a smooth marble slab, where it is allowed to congeal. The sulphur immediately takes fire, and, by combining with oxygen from a part of the nitric acid of the nitre, becomes sulphuric acid, which then unites with a small portion of potassa, to form sulphate of potassa.

Medical Properties. Nitre is considered refrigerant, diuretic, and diaphoretic, and is much used in inflammatory diseases. It is known to be a powerful antiseptic. It generally promotes the secretion of urine and sweat, lessens the heat of the body and the frequency of the pulse, and has a tendency to keep the bowels in a soluble condition. When taken in health, in quantities increasing gradually from one to five drachms daily, for the space of from eight to twelve days, it was found by F. Löffler to produce general weakness, lowness of spirits, constant disposition to sleep, and slow and weak pulse. Towards the end of the experiment, the pulse several times fell to twenty beats in the minute. During the use of the medicine, the appetite and digestion continued good, and the bowels were regular; though, occasionally, some pain was experienced in the abdomen, followed by purging. The blood, drawn at the end of the period, resembled cherry juice in colour, exhibited paler blood corpuscles than in health, coagulated very quickly, forming a clot of diminished firmness, was more watery than natural, and diminished in the proportion of its fat. (*Am. Journ. of Med. Sci.*, xviii. 204, from *Schmidt's Jahrb.*)

Nitre is very frequently prescribed with tartar emetic and calomel, forming a combination usually called the *nitrous powder*, which promotes most of the secretions, particularly those of the liver and skin, and which in many cases is advantageously employed in lessening and modifying febrile excitement. The formula usually preferred is eight or ten grains of nitre, the eighth of a grain of tartar emetic, and from the fourth to the half of a grain of calomel, exhibited every two or three hours. Nitre is frequently given in active hemorrhages, particularly hæmoptysis, and is a useful ingredient of gargles, in certain stages of inflammatory sorethroat. Dr. Frisi, an Italian physician, found it very efficacious in a case of obstinate spasmodic asthma, in affording speedy relief, and cutting short the attack as often as it was repeated. In the same disease, nitrous fumigation has been found useful, performed by inhaling for a quarter of an hour the fumes from burning touch paper, prepared by dipping blotting paper in a saturated solution of nitre, and afterwards drying it. In the form of sal prunelle, it is rubbed on chapped lips. The dose is from ten to fifteen grains, dissolved in water or some mucilaginous liquid, and repeated every two or three hours. From one to three drachms may be exhibited in the course of the day. If given too freely, or for too long a period, it is apt to excite pain in the stomach. In an overdose (half an ounce to an ounce or more), taken in concentrated solution, it causes heat and pain in the stomach, vomiting and purging of blood, great prostration, convulsions, and sometimes death. On dissection, the stomach and intestines are found inflamed. The treatment consists in the speedy removal of the poison from the stomach, and in the administration of mucilaginous drinks, laudanum to allay pain and irritation, and cordials to sustain the system. No antidote is known.

Notwithstanding the toxical properties of nitre when taken in a large dose in concentrated solution, it may be given, in divided doses, to the extent of one or two ounces in twenty-four hours, provided it be largely diluted with water. It is principally in acute rheumatism that large doses of this salt have been given; and both M. Gendrin and M. Martin-Solon bear testimony to its remarkable efficacy in that disease, after ample experience with its use in two of the hospitals of Paris. Dr. Henry Bennett, of London, also speaks highly of its efficacy in the same disease. It may be given in quantities, varying from six to sixteen drachms in twenty-four hours, dissolved in sweetened barley water, in the proportion of half an ounce of the salt to a pint and a half or two pints of the liquid. Administered in this way, the principal action of the salt is that of a sedative on the circulation, decreasing the force and frequency of the pulse.

Pharmaceutical Uses, &c. In pharmacy nitre is employed to form crocus of

antimony, and to procure nitric acid. It is also used in the formula of the U. S. Pharmacopœia for obtaining sweet spirit of nitre. It enters into the composition of moxa, and is employed in preparing the sulphate of potassa with sulphur of the Edinburgh College. In the laboratory it is used as an oxidizing agent, and to yield oxygen at a red heat. In the arts it is employed in the production of aqua fortis (common nitric acid), the manufacture of sulphuric acid, and the fabrication of gunpowder.

POTASSÆ SULPHAS. *U. S., Lond., Ed., Dub.*

Sulphate of Potassa.

Vitriolated tartar: Tartarum vitriolatum, Arcanum duplicatum, Sal de duobus, *Lat.;* Sulfate de potasse, Potasse vitriolée, *Fr.;* Schwefelsaures Kali, Vitriolisirtir Weinstein, *Germ.;* Solfato di potassa, *Ital.*

Several chemical processes give rise to sulphate of potassa as a secondary product. Thus, it is produced in the distillation of nitric acid from a mixture of nitre with sulphuric acid; in the decomposition of sulphate of magnesia by carbonate of potassa, in one of the processes for preparing carbonate of magnesia; during the combustion of the mixture of nitre and sulphur in the manufacture of sulphuric acid; and in the decomposition of tartrate of potassa by sulphate of lime. (See *Acidum Nitricum*, *Acidum Sulphuricum*, and *Acidum Tartaricum.*) When nitric acid is obtained by calcining a mixture of nitre and sulphate of iron, the residue consists of sesquioxide of iron and sulphate of potassa, the latter of which, being alone soluble, is separated by means of water, and crystallized from its solution. The residue of the combustion of sulphur and nitre, in making sulphuric acid, is an impure sulphate of potassa mixed with sulphur, which is sold to the alum makers.

The U. S. and London Pharmacopœias place sulphate of potassa in the list of the Materia Medica; the Edinburgh and Dublin, among the preparations, obtaining it from the salt which remains after the distillation of nitric acid. This salt is a supersulphate of potassa, and must be so treated as to bring it to the neutral state. The Edinburgh College brings it to that state by removing the excess of acid by the addition of white marble, which converts it into an insoluble sulphate of lime. The Dublin College saturates the supersalt in boiling solution with slaked lime; strains the solution to separate the sulphate of lime; adds carbonate of potassa at the boiling temperature, to remove lime and sulphate of lime; strains again; exactly neutralizes the strained liquor with diluted sulphuric acid; and, finally, having evaporated it to a pellicle, sets it aside for twenty-four hours to crystallize.

The manufacturer of tartaric acid who avails himself of sulphate of lime to decompose the tartrate of potassa, forms sulphate of potassa as a collateral product. For the manner in which the latter salt may be economically crystallized for use in the arts, see *Am. Journ. of Pharm.*, xxiii. 343.

Properties. Sulphate of potassa is a white, anhydrous salt, in the form of small, aggregated, transparent, very hard crystals, permanent in the air, having the shape usually of short six-sided prisms, terminated by six-sided pyramids, and possessing a nauseous, somewhat bitter taste. Insoluble in alcohol, it is slowly soluble in about nine and a half times its weight of cold, and in less than four times its weight of boiling water. (*Gay-Lussac.*) Its solution is precipitated yellow by chloride of platinum, and white by chloride of barium. Added to a solution of sulphate of alumina, it generates alum, recognised by the octo-

hedral shape of its crystals. It is decomposed by tartaric acid, which forms bitartrate of potassa, and by the soluble salts of baryta, strontia, lime, silver, and lead, forming insoluble or sparingly soluble sulphates. This salt is not subject to adulteration. It consists of one eq. of sulphuric acid 40, and one of potassa 47·2=87·2.

Medical Properties and Uses. Sulphate of potassa is a mild purgative, operating without heat, pain, or other symptoms of irritation. In small doses of from a scruple to half a drachm, it operates as an aperient, and is useful in removing obstructions; in larger doses, of four or five drachms, it acts slowly as a purge. Combined with rhubarb, in the proportion of about a drachm of the salt to ten grains of the root, Dr. Fordyce found it an excellent alterative cathartic in the visceral obstructions of children, characterized by a tumid abdomen, and defective digestion and nutrition; and we can bear testimony to its efficacy in these cases. The late Dr. A. T. Thomson found this salt, in combination with rhubarb or aloes, "more useful than any of the other saline purgatives, in jaundice and dyspeptic affections." On the continent of Europe it is frequently given as an aperient after delivery, and for the purpose of drying up the milk. It enters into the composition of Dover's powder.

Notwithstanding the general sentiment of practitioners as to the mildness and safety of sulphate of potassa as a purgative, several cases have been reported in the Journals of supposed poisoning from its use. M. Moritz attributed the poisonous effects of the salt, in the case which came under his notice, to the presence of a notable quantity of sulphate of zinc; but his explanation cannot be admitted as adequate. In other cases, the salt, though found to be pure, seemed to act as a poison. Still, we are not disposed to admit that sulphate of potassa is poisonous. In the cases in which it apparently acted as such, its effects may be attributed sometimes to the largeness of the dose in which it was administered, and perhaps also to the insufficiency of the water used to dissolve it; at other times, where the dose used was moderate, to the existence of a predisposition to gastric inflammation. For further information in relation to this subject, the reader is referred to a paper by Dr. T. Romeyn Beck, in the *Amer. Journ. of the Med. Sci.*, N. S., vii. 88.

POTASSII FERROCYANURETUM. *U.S.*

Ferrocyanuret of Potassium.

Off. Syn. POTASSII FERROCYANIDUM. *Lond., Ed., Dub.*

Ferrocyanide of potassium, Ferrocyanate of potassa, Ferroprussiate of potassa, Prussiate of potassa; Proto-cyanure jaune de fer et de potassium, *Fr.;* Cyaneisenkalium, *Germ.*

This is the yellow double cyanuret of potassium and iron, the salt from which the cyanuret of potassium is obtained by calcination at a low red heat. (See *Potassii Cyanuretum.*)

Ferrocyanuret of potassium is prepared on a large scale by calcining animal matters, such as dried blood, hoofs, chips of horn, woollen rags, old leather, the refuse of tallow-chandlers, called *greaves*, and other substances rich in nitrogen, with the pearlash of commerce, in an egg-shaped iron pot, called a shell, dissolving the calcined mass, after cooling, in water, and evaporating the solution so that crystals may form. The requisite iron for forming the salt is derived from the pots and stirrers used in the process. Occasionally iron filings are added.

A new process for manufacturing this salt, carried into successful operation at New Castle-on-Tyne by MM. Possoz and Boissière, dispenses with the use of

animal matters; the necessary nitrogen being obtained by a current of atmospheric air. In this process fragments of charcoal, impregnated with thirty per cent. of carbonate of potassa, are heated to white redness in a cylinder, through which a current of air is drawn by a suction pump. For further details in relation to this process, see the paper of Mr. Ambrose Smith on the manufacture of this salt, contained in the *Am. Journ. of Pharmacy*, for July, 1848, p. 178.

Properties. Ferrocyanuret of potassium is in large, beautiful, transparent, permanent, four-sided, tabular crystals, of a lemon-yellow colour, devoid of odour, but possessing a sweetish, yet somewhat bitter, saline taste. It dissolves in between three and four times its weight of cold water, and in about its own weight of boiling water, but is insoluble in alcohol. It acts but slightly, if at all, on turmeric paper. The alkaline reaction, when it occurs, is probably owing to the presence of a little free potassa retained by the water of crystallization. When heated to 140° it loses its water of crystallization, amounting to 12·6 per cent., and becomes white. When ignited, the insoluble residue amounts to 18·7 per cent. of sesquioxide of iron, resulting from the oxidation of the iron of the salt. It is characterized by striking a deep blue colour with the salts of sesquioxide of iron, a deep brown one with the salts of copper, and a white one with those of zinc, the several precipitates formed being ferrocyanurets of the respective metals. Heated with eight or ten times its weight of concentrated sulphuric acid, a large quantity of pure carbonic oxide is evolved. (*Fownes.*) When boiled with dilute sulphuric acid, it emits the smell of hydrocyanic acid. Ferrocyanuret of potassium consists of two eqs. of cyanuret of potassium 130·4, one of cyanuret of iron 54, and three of water 27 = 211·4. The water present is just sufficient to convert the iron and potassium into protoxides, and the cyanogen into hydrocyanic acid. Apart from the water present, it is generally considered to consist of a compound radical, called *ferrocyanogen*, formed of three eqs. of cyanogen and one of iron (tercyanuret of iron), united with two eqs. of potassium. Hence its officinal name. This salt is remarkably pure as it occurs in commerce.

Medical Properties, &c. Judging from the experiments of the German physicians, this salt possesses but little activity. Callies, as quoted by Pereira, found the commercial salt slightly poisonous, but the pure salt unproductive of harm in the dose of several ounces. It should be borne in mind that it is the commercial salt which is used medicinally. Westrumb and Hering proved that it passed with rapidity into the blood and urine.

Notwithstanding these statements, the late Dr. Burleigh Smart, of Kennebec, Maine, found this salt to possess active medicinal powers. (*Am. Journ. of Med. Sci.*, xv. 362.) Its primary effect was that of a sedative, diminishing the fulness and frequency of the pulse, and allaying pain and irritation. It acted also, under favourable circumstances, as a diaphoretic and astringent. Dr. Smart used it with success in a case of chronic bronchitis in a child, with the effect, in a few days, of diminishing the frequency of the pulse, and of lessening the sweating, cough, and dyspnœa. It sometimes acted as a diaphoretic, but only in cases attended with excessive vascular action and increased heat of skin. As an astringent its power was most conspicuous in the colliquative sweats of chronic bronchitis and phthisis. The same power was evinced in several cases of leucorrhœa cured by its use. It sometimes produced ptyalism, unattended, however, by swelling of the salivary glands or fetor of the breath. Its properties as an anodyne and sedative rendered it applicable to cases of neuralgic pains and whooping cough, in which diseases, especially the latter, Dr. Smart found it useful. When given in an overdose he stated that it occasioned vertigo, coldness, and numbness, with a sense of gastric sinking.

The form of administration which Dr. Smart preferred was that of solution, in the proportion of two drachms to the fluidounce of water. Of this the dose for an

adult was from 30 to 45 drops, equivalent to from 10 to 15 grains of the salt, repeated every four or six hours.

This salt is manufactured on a large scale, chiefly for the use of dyers and calico-printers. In pharmacy it is employed to prepare diluted hydrocyanic acid, Prussian blue, and the cyanurets of potassium and silver.

PRINOS. *U. S. Secondary.*

Black Alder.

The bark of Prinos verticillatus. *U. S.*

Prinos. *Sex. Syst.* Hexandria Monogynia.—*Nat. Ord.* Aquifoliaceæ.

Gen. Ch. Calyx small, six-cleft. *Corolla* monopetalous, subrotate, six-parted. *Berry* six-seeded; seeds nuciform. *Nuttall.*

Prinos verticillatus. Willd. *Sp. Plant.* ii. 225; Bigelow, *Am. Med. Bot.* iii. 141; Barton, *Med. Bot.* i. 203. The black alder is an indigenous shrub, with a stem six or eight feet high, furnished with alternate, spreading branches, and covered with a bluish-gray bark. The leaves, which stand alternately or irregularly on short petioles, are oval, pointed, tapering at the base, acutely serrate, of a dark-green colour, smooth on their upper surface, but downy on the veins beneath. The flowers are small, white, nearly sessile, and grow three or four together at the axils of the leaves. They are often dicœcious. The calyx is persistent; the segments of the corolla obtuse; the stamens usually six in number, and furnished with oblong anthers; the germ large, green, roundish, and surmounted by a short style, terminating in an obtuse stigma. The fruit when ripe consists of glossy, scarlet, roundish berries, about the size of a pea, containing six cells and six seeds. Several of these berries are clustered together so as to form little bunches at irregular intervals on the stem. In the latter part of autumn, after the leaves have fallen, they still remain attached to the stem, and render the shrub a striking object in the midst of the general nakedness of vegetation. Hence the plant has received the name of *winter-berry*, by which it is frequently designated.

It grows in all parts of the United States, from Canada to Florida, frequenting low wet places, such as swamps, and the borders of ponds, ditches, and streams. Its flowers appear in June. The berries, which have a bitter, sweetish, somewhat acrid taste, are sometimes used medicinally for the same purposes with the bark, which is the officinal portion.

The dried bark is in slender pieces, more or less rolled, brittle, greenish-white internally, and covered with a smooth epidermis, easily separable, and of a whitish-ash colour, alternating or mingled with brown. It has no smell, but a bitter and slightly astringent taste. Boiling water extracts its virtues.

Medical Properties and Uses. Black alder is usually considered tonic and astringent; and is among the remedies proposed as substitutes for Peruvian bark, with which, however, it has very little analogy. It has been recommended in intermittent fever, diarrhœa, and other diseases connected with debility, especially gangrene and mortification. It is a popular remedy in gangrenous or flabby and ill-conditioned ulcers, and in chronic cutaneous eruptions, in which it is given internally, and applied locally in the form of a wash or poultice. It may be used in substance or decoction. The dose of the powder is from thirty grains to a drachm, to be repeated several times a day. The decoction, which is usually preferred both for internal and external use, may be prepared by boiling two ounces of the bark with three pints of water to a quart, and given in the dose of two or three fluidounces. A saturated tincture, as well of the berries as of the bark, is sometimes employed. W.

PRUNUM. *U. S., Lond.*

Prunes.

The dried fruit of Prunus domestica. *U. S.* The prepared fruit. *Lond.*

Off. Syn. PRUNA. Dried fruit of Prunus domestica. *Ed., Dub.*

Pruneaux, *Fr.;* Pflaumen, *Germ.;* Pruni, *Ital.;* Ciruelas secas, *Span.*

PRUNUS. *Sex. Syst.* Icosandria Monogynia.—*Nat. Ord.* Amygdalcæ.

Gen. Ch. Calyx inferior, bell-shaped, deciduous, with five obtuse, concave segments. *Petals* five, roundish, concave, spreading, larger than the segments of the calyx, into the rim of which they are inserted. *Filaments* awl-shaped, nearly as long as the corolla, from the rim of the calyx within the petals. *Anthers* short, of two round lobes. *Ovary* superior, roundish. *Style* of the length of the stamens. *Stigma* orbicular, peltate. *Drupe* roundish or elliptical. *Nut* hard, somewhat compressed, of one cell, and two more or less distinct sutures with an intermediate furrow. *Leaves* rolled up when young. (*Lindley.*)

Prunus domestica. Willd. *Sp. Plant.* ii. 995; Woodv. *Med. Bot.* p. 520, t. 187. The cultivated prune or plum tree is so well known as to render a minute description unnecessary. We merely give the specific character. "*Peduncles* subsolitary; *leaves* lanceolate-ovate, convolute; *branches* not spiny." The varieties of the tree produced by cultivation are very numerous. Nearly one hundred are to be found in the British gardens. Though at present growing wild in various parts of Europe, it is thought to have been brought originally from Asia Minor and Syria. It is the dried fruit only that is officinal.

The prunes brought to our market come chiefly from the South of France, the best from the port of Bordeaux. They are derived from the variety of the tree named *Juliana* by Linnæus. The fresh fruit, called *Prune de Saint Julien* by the French, is of an oval shape, nearly an inch in length, and of a deep violet colour. It is prepared by drying in the sun, after having been exposed to the heat of an oven. The finest prunes, used on the tables in France, are prepared from the larger kinds of plums, such as the *Saint Catharine* and *Reine-Claude* or *green-gage.* An inferior sort is brought from Germany.

Prunes have a feeble odour, and a sweet mucilaginous taste, which is generally also somewhat acid. They contain uncrystallizable sugar, malic acid, and mucilaginous matter. In Germany there is obtained from this fruit a kind of brandy, which in some districts is largely consumed. Bonneberg, a German chemist, has extracted from prunes crystallizable sugar, equal to that of the cane.

Medical Properties and Uses. Prunes are laxative and nutritious, and stewed with water form an excellent diet in costiveness, especially during convalescence from febrile and inflammatory diseases. Imparting their laxative property to water in which they are boiled, they serve as a pleasant and useful addition to purgative decoctions. Their pulp is used in the preparation of laxative confections. Too largely taken in a debilitated state of the digestive organs, they are apt to occasion flatulence, and griping pain in the stomach and bowels.

PRUNUS VIRGINIANA. *U. S.*

Wild-cherry Bark.

The bark of Cerasus serotina (*De Cand.*), Cerasus Virginiana (*Michaux*). *U. S.*

CERASUS. See LAURO-CERASUS.

This genus, which is now generally admitted, includes a large number of species formerly embraced in the genus Prunus of Linnæus.

Cerasus serotina. De Candolle. *Prodrom.* ii. 540; Torrey and Gray, *Flora of N. America*, i. 410.—*Cerasus Virginiana.* Michaux, *N. Am. Sylv.* ii. 205. According to Torrey and Gray, the name *Prunus Virginiana*, which has frequently been applied to this species, was given by Linnæus to the *choke-cherry*, a small tree or shrub, growing in the Northern States, and bearing a dark-red, globular, astringent fruit, about as large as that of the *wild-cherry*. This is described in the Flora of N. America of these authors, under the name of *Cerasus Virginiana*. The officinal species, or wild-cherry tree, is, according to Michaux, one of the largest productions of the American forest. Individuals were seen by that botanist on the banks of the Ohio from eighty to one hundred feet high, with trunks from twelve to fifteen feet in circumference, and undivided to the height of twenty-five or thirty feet. But, as usually met with in the Atlantic States, the tree is much smaller. In the open fields it is less elevated than in forests, but sends out more numerous branches, which expand into an elegant oval summit. The trunk is regularly shaped, and covered with a rough blackish bark, which detaches itself semicircularly in thick narrow plates, and by this peculiar character serves as a distinguishing mark of the tree, when the foliage is too high for inspection. The leaves are oval-oblong, or lanceolate-oblong, acuminate, unequally serrate, smooth on both sides, of a beautiful brilliant green, and supported alternately upon petioles, which are furnished with from two to four reddish glands. The flowers are small, white, and collected in long erect or spreading racemes. They appear in May, and are followed by globular drupes about the size of a pea, and when ripe of a shining blackish-purple colour.

This tree grows throughout the Union, flourishing most in those parts where the soil is fertile and the climate temperate, and abounding in the Middle Atlantic States, and in those which border on the Ohio. In the neighbourhood of Philadelphia, it affects open situations, growing solitarily in the fields and along fences, and seldom aggregated in woods or groves. It is highly valued by the cabinet-makers for its wood, which is compact, fine-grained, susceptible of polish, and of a light-red tint, which deepens with age. The fruit has a sweetish, astringent, bitter taste; and is much employed in some parts of the country to impart flavour to spirituous liquors. The inner bark is the part employed in medicine, and is obtained indiscriminately from all parts of the tree, though that of the roots is thought to be most active. Mr. J. S. Perot has ascertained that it is much stronger when collected in autumn than in the spring. Thus, from a portion gathered in April he obtained ·0478 per cent. of hydrocyanic acid, and from another in October ·1436 per cent., or about three times as much from the latter as the former. The parcels tried were taken from the same tree, and the same part of the tree. (*Am. Journ. of Pharm.*, xxiv. 111.) The bark should be preferred recently dried, as it deteriorates by keeping.

Properties. Wild-cherry bark, as kept in the shops, is in pieces of various sizes, more or less curved laterally, usually destitute of epidermis, of a lively reddish-cinnamon colour, brittle, and pulverizable, presenting a reddish-gray fracture, and affording a fawn-coloured powder. In the fresh state, or when treated with water, it emits an odour resembling that of peach leaves. Its taste is agreeably bitter and aromatic, with the peculiar flavour of the bitter almond. It imparts its sensible properties to water, either cold or hot, producing a clear reddish infusion, closely resembling Madeira wine in appearance. Its peculiar flavour as well as medical virtues are injured by boiling, in consequence partly of the volatilization of the principle upon which they depend, partly upon a chemical change effected by the heat. From an analysis by Dr. Stephen Procter, it appears to contain starch, resin, tannin, gallic acid, fatty matter, liguin, red colouring matter, salts of lime and potassa, and iron. He obtained also a volatile oil, associated with hydrocyanic acid, by distilling the same portion of water succes-

sively from several different portions of the bark. This oil was of a light-straw colour, and very analogous in its properties to the volatile oil of bitter almonds. In the quantity of two drops it proved fatal to a cat in less than five minutes. *Journ. of the Phil. Col. of Pharm.*, vi. 8.) Prof. William Procter proved that, as in the case of bitter almonds, the volatile oil and hydrocyanic acid do not exist ready formed in the bark, but are the result of the reaction of water upon amygdalin, which he ascertained to be one of its constituents. In order, however, that this change may take place, the agency of another principle, probably analogous to if not identical with *emulsin*, or the *synaptase* of Robiquet, is also essential; and, as this principle becomes inoperative at the boiling temperature, we can understand how decoction may interfere with the virtues of the bark. (*Am. Journ. of Pharm.*, x. 197.) The conjecture was advanced, in former editions of this work, that wild-cherry bark might contain also *phloridzin*, a bitter principle proved to exist in the bark of the apple, pear, cherry, and plum trees. (See *Phloridzin* in the Appendix.) But Mr. Perot sought for this principle, without success, in specimens of the bark of different ages, and taken from different parts of the tree; so that the tonic property, which is undoubtedly possessed by the bark, must reside either in the portion of amygdalin which may remain undecomposed, in the pure volatile oil resulting from its reaction with water, or in some yet undiscovered principle. The sedative properties of the bark depend upon the hydrocyanic acid which it yields. (*Ibid.*, xxiv. 111.)

Medical Properties and Uses. This bark is among the most valuable of our indigenous remedies. Uniting with a tonic power the property of calming irritation and diminishing nervous excitability, it is admirably adapted to the treatment of diseases in which debility of the stomach, or of the system, is united with general or local irritation. When largely taken it is said to diminish the action of the heart, an effect ascribable to the hydrocyanic acid. Dr. Eberle found copious draughts of the cold infusion, taken several times a day, and continued for nearly two weeks, to reduce his pulse from seventy-five to fifty strokes in the minute. The remedy is highly useful, and has been much employed in this country, in the hectic fever of scrofula and consumption. In the general debility which often succeeds inflammatory diseases, it is also advantageous; and it is well adapted to many cases of dyspepsia. It has been given successfully in intermittent fever, but is much inferior to cinchona.

It may be used in powder or infusion. The dose of the powder is from thirty grains to a drachm. The infusion is properly directed by our national Pharmacopœia to be prepared with cold water. (See *Infusum Pruni Virginianæ.*) A syrup of wild-cherry bark was introduced into the last edition of the Pharmacopœia, and is considerably used. (See *Syrupus Pruni Virginianæ.*)

PYRETHRUM. *U.S. Secondary, Lond., Ed.*

Pellitory.

The root of Anacyclus Pyrethrum. *U. S., Lond., Ed.*

Pyrèthre, *Fr.;* Bertram Wurzel, *Germ.;* Piretro, *Ital.;* Pelitre, *Span.*

Anacyclus. Differing from Anthemis by its winged and obcordate *Achænia. Lindley.* See ANTHEMIS.

Anacyclus Pyrethrum. De Cand. *Prodrom.* vi. 15.—*Anthemis Pyrethrum.* Willd. *Sp. Plant.* iii. 2184; Woodv. *Med. Bot.* p. 50, t. 20. The root of this plant is perennial, and sends up numerous stems, usually trailing at the base, erect in their upper portion, eight or ten inches high, and terminated by one large flower. The leaves are doubly pinnate, with narrow nearly linear segments of a pale-green colour. The florets of the disk are yellow; the rays white on their upper surface, and reddish or purple beneath and at their edges.

The plant is a native of the Levant, Barbary, and the Mediterranean coast of Europe. The root is the part used under the name of pellitory, or *pellitory of Spain.* According to Hayne, the pellitory of the shops is derived from the *Anacyclus officinarum,* a plant cultivated in Thuryngia for medical purposes. This remark, however, can apply only to Germany.

Properties. The dried root of *A. Pyrethrum* is about the size of the little finger, cylindrical, straight or but slightly curved, wrinkled longitudinally, of an ash-brown colour externally, whitish within, hard and brittle, and sometimes furnished with a few radicles. It is destitute of odour, though, when fresh, of a disagreeable smell. Its taste is peculiar, slight at first, but afterwards acidulous, saline, and acrid, attended with a burning and tingling sensation over the whole mouth and throat, which continues for some time, and excites a copious flow of saliva. Its analysis by Koene gives, in 100 parts, 0·59 of a brown, very acrid substance, of a resinous appearance, and insoluble in caustic potassa; 1·60 of a dark-brown, very acrid fixed oil, soluble in potassa; 0·35 of a yellow acrid oil, also soluble in potassa; traces of tannin; 9·40 parts of gum; inulin; 7·60 parts of sulphate and carbonate of potassa, chloride of potassium, phosphate and carbonate of lime, alumina, silica, &c.; and 19·80 of lignin, besides loss. (See *Am. Journ. of Pharm.,* viii. 175.)

Medical Properties and Uses. Pellitory is a powerful irritant, used almost exclusively as a sialagogue in certain forms of headache, rheumatic and neuralgic affections of the face, toothache, &c., or as a local stimulant in palsy of the tongue or throat, and in relaxation of the uvula. For these purposes it may be chewed, or employed as a gargle in decoction or vinous tincture. The dose as a masticatory is from thirty grains to a drachm. An alcoholic extract is sometimes employed by dentists as a local application to carious teeth, with a view to its benumbing effect before plugging. W.

QUASSIA. *U.S., Lond., Ed., Dub.*

Quassia.

The wood of Simaruba excelsa. *U.S.* Picræna excelsa. The wood. *Lond., Dub.* Wood chiefly of Picræna excelsa, seldom of Quassia amara. *Ed.*

Bois de quassie, *Fr.;* Quassienholz, *Germ.;* Legno della quassia, *Ital.;* Leno de quassia, *Span.*

Quassia. *Sex. Syst.* Decandria Monogynia.—*Nat. Ord.* Simarubaceæ.

Gen. Ch. Calyx five-leaved. *Petals* five. *Nectary* five-leaved. *Drupes* five, distant, bivalve, one-seeded, inserted into a fleshy receptacle. *Willd.*

Of the species included by Linnæus in this genus, some, as *Quassia amara*, are hermaphrodite; others, as *Q. excelsa* and *Q. Simaruba*, are monœcious or polygamous. The latter have been associated together by De Candolle, in a distinct genus, with the title *Simaruba*. This has been again divided by Lindley into *Simaruba* with monœcious, and *Picræna* with polygamous flowers. To the last-mentioned genus the proper quassia plant, the Q. excelsa of Linnæus, belongs.

The medicine was formerly thought to be obtained from *Quassia amara;* but more than twenty years since, Lamarck stated that, in consequence of the scarcity of this tree, *Quassia excelsa* had been resorted to as a substitute, and the Pharmacopœias at present agree in acknowledging the latter as the officinal plant. Martius, however, thinks that the genuine quassia plant of Surinam is the *Q. amara;* and we shall, therefore, give a brief description of both species.

Quassia excelsa. Willd. *Sp. Plant.* ii. 569.—*Simaruba excelsa*, De Cand. *Prodrom.* i. 733; Hayne, *Darstel. und Beschreib.* &c. ix. 16.—*Picræna excelsa.* Lindley, *Flor. Med.* 208. As its name imports, this is a lofty tree, attaining sometimes not less than one hundred feet in height, with a straight, smooth, tapering trunk, which is often three feet in diameter near its base, and covered with a smooth gray bark. The leaves are pinnate, with a naked petiole, and oblong pointed leaflets standing upon short footstalks, in opposite pairs, with a single leaflet at the end. The flowers are small, of a yellowish-green colour, and disposed in panicles. They are polygamous and pentandrous. The fruit is a small black drupe. This species inhabits Jamaica and the Caribbean islands, where it is called *bitter ash.* The wood is the officinal portion.

Quassia amara. Willd. *Sp. Plant.* ii. 567; Woodv. *Med. Bot.* p. 574, t. 204. The bitter quassia is a small branching tree or shrub, with alternate leaves, consisting of two pairs of opposite pinnæ, with an odd one at the end. The leaflets are elliptical, pointed, sessile, smooth, of a deep-green colour on their upper surface, and paler on the under. The common footstalk is articulated, and edged on each side with a leafy membrane. The flowers, which are hermaphrodite and decandrous, have a bright-red colour, and terminate the branches in long racemes. The fruit is a two-celled capsule, containing globular seeds. Quassia amara is a native of Surinam, and is said also to grow in some of the West India islands. Its root, bark, and wood were formerly officinal. They are excessively bitter, as in fact are all parts of the plant. It is uncertain whether any of the produce of this tree reaches our markets.

Quassia comes in cylindrical billets of various sizes, from an inch to near a foot in diameter, and several feet in length. These are frequently invested with a whitish smooth bark, brittle, and but slightly adherent, and possessing in at least an equal degree the virtues of the wood. Their shape and structure clearly evince that they are derived from the branches or trunk, and not, as some have supposed, from the root of the tree. In the shops they are usually kept split into small pieces, or rasped.

Properties. The wood is at first whitish, but becomes yellow by exposure. It is inodorous, and has a purely bitter taste, surpassed by that of few other substances in intensity and permanence. It imparts its active properties, with its bitterness and yellow colour, to water and alcohol. Its virtues depend upon a peculiar bitter crystallizable principle, denominated *quassin*, which was first discovered by Winckler. It may be obtained pure by the following process of Wiggers. A filtered decoction of quassia is evaporated to three-quarters of the weight of the wood employed, slaked lime is added, and the mixture having

been allowed to stand for a day, with occasional agitation, is again filtered. A considerable quantity of pectin, besides other substances, is thus separated. The clear liquor is evaporated nearly to dryness, and the resulting mass exhausted by alcohol of the sp. gr. 0·835, which leaves behind gum, common salt, nitre, &c., in large amount, and dissolves quassin with some common salt and nitre, and an organic substance of a brown colour. In order to separate the quassin from these latter principles, which are soluble in water, the solution is evaporated to dryness, the resulting mass is dissolved in the least possible quantity of absolute alcohol, a large proportion of ether is added, and the liquor, previously separated by filtration from the brown mass which the ether has thrown down, is evaporated to dryness; and this process is repeated till the quassin remains behind quite colourless, and affords no evidence of the presence of the abovementioned salts. Lastly, in order to obtain it in a crystalline form, to which it is not strongly disposed, pour the alcoholic solution mixed with ether upon a little water, and allow it to evaporate spontaneously. *Quassin* is white, opaque, unalterable in the air, inodorous, and of an intense bitterness, which in the solutions of this principle is almost insupportable. The bitterness is pure, and resembles that of the wood. When heated, quassin melts like a resin. It is but slightly soluble in water, 100 parts of which at 54° dissolve only 0·45, and that slowly. By the addition of salts, especially of those with which it is associated in quassia, its solubility is strikingly increased. It is also but slightly soluble in ether, but is very soluble in alcohol, more so in that liquid hot than cold, and the more so the purer it is. Quassin is perfectly neuter, though both alkalies and acids increase its solubility in water. It is precipitated by tannic acid from its aqueous solution, which is not disturbed by iodine, chlorine, corrosive sublimate, solutions of iron, sugar of lead, or even the subacetate of lead. Its ultimate constituents are carbon, hydrogen, and oxygen.

Medical Properties and Uses. Quassia has in the highest degree all the properties of the simple bitters. It is purely tonic, invigorating the digestive organs, with little excitement of the circulation, or increase of animal heat. It has not been very long known as a medicine. About the middle of the last century, a negro of Surinam, named Quassi, acquired considerable reputation in the treatment of the malignant fevers of that country, by a secret remedy, which he was induced to disclose to Mr. Rolander, a Swede, for a valuable consideration. Specimens were taken to Stockholm by this gentleman in the year 1756; and the medicine soon became popular in Europe. The name of the negro has been perpetuated in the generic title of the plant. But the quassia of Surinam is not now in use, having been superseded by the product of Quassia excelsa, from the West Indies. This medicine is useful whenever a simple tonic impression is desirable. It is particularly adapted to dyspepsia, and to that debilitated state of the digestive organs which sometimes succeeds acute disease. It may also be given with advantage in the remission of certain fevers in which tonics are demanded. No one at present would expect from it any peculiar controlling influence over malignant fevers. It is said to be largely employed in England by the brewers, to impart bitterness to their liquors.

It is most conveniently administered in infusion or extract. (See *Infusum Quassiæ* and *Extractum Quassiæ*.) The difficulty of reducing the wood to powder is an objection to its use in substance. It may, however, be employed in a dose varying from a scruple to a drachm, repeated three or four times a day. Some dyspeptic patients, who have become habituated to its bitterness, chew the wood occasionally with benefit.

Gen. Ch. MALE. *Calyx* commonly five-cleft. *Corolla* none. *Stamens* five to ten. FEMALE. *Calyx* one-leafed, entire, rough. *Corolla* none. *Styles* two to five. *Nut* coriaceous, surrounded at the base by the persistent calyx. *Willd.*

This extensive genus comprises not less than eighty species, of which between thirty and forty are within the limits of the United States. Many of these are applied to important practical purposes. In the northern hemisphere, the oak is the most valuable, as it is the most widely diffused of all forest trees. Notwithstanding the great number of species, few, comparatively, have found a place in the officinal catalogues. *Q. robur*, or common European oak, was formerly recognised by the British Colleges; but at present they admit only *Q. pedunculata*, or European white oak. As these do not grow in the United States, and their products are not imported, it is unnecessary to treat of them particularly in this work. According to Michaux, they grow in the same countries, frequently together, constituting the greater part of the forests of Europe, and spreading over almost the whole northern section of Asia, and the northern coast of Africa. *Q. pedunculata* is the common British oak, celebrated as well for its majestic growth and the venerable age which it attains, as for the strength and durability of its timber. Our own Pharmacopœia recognises only *Q. alba* or white oak, and *Q. tinctoria* or black oak; but several other species afford barks which are equally useful, and perhaps as much employed. Such are *Q. falcata* or Spanish oak, *Q. prinus* or white chestnut oak, and *Q. montana* or rock chestnut oak. The remarks which follow in relation to the white-oak bark, will apply also to that of the three last-mentioned species. The bark of *Q. tinctoria* is somewhat peculiar.

1. *Quercus alba.* Willd. *Sp. Plant.* iv. 448; Michaux, *N. Am. Sylv.* i. 17. Of all the American species, the *white oak* approaches nearest, in the character of its foliage, and the properties of its wood and bark, to the *Q. pedunculata* of Great Britain. When allowed to expand freely in the open field, it divides at a short distance from the ground into numerous widely spreading branches, and attains under favourable circumstances a magnificent size. Its trunk and large branches are covered with a whitish bark, which serves to distinguish it from most of the other species. The leaves are regularly and obliquely divided into oblong, obtuse, entire lobes, which are often narrowed at their base. When full grown, they are smooth and light green on their upper surface, and glaucous beneath. Some of the dried leaves remain on the tree during the whole winter. The acorns are large, ovate, contained in rough, shallow, grayish cups, and supported singly or in pairs upon peduncles nearly an inch in length.

The white oak abounds in the Middle States, and extends also through the whole Union, though comparatively rare in the northern, southern, and western sections. It is the most highly valued for its timber of all the American oaks, with the exception of the *live oak* (*Q. virens*), which is preferred in ship-building. The bark is sometimes used for tanning, but that of the *red* and *Spanish oaks* is preferred for this purpose. All parts of the tree, with the exception of the epidermis, are more or less astringent, but this property predominates in the fruit and bark.

White-oak bark, deprived of its epidermis, is of a light-brown colour, of a coarse fibrous texture, and not easily pulverized. It has a feeble odour, and a rough, astringent, and bitterish taste. Water and alcohol extract its active properties. The chief soluble ingredients are tannin, gallic acid, and extractive matter. It is upon the tannin that its medical virtues, as well as its use in the preparation of leather, chiefly depend. The proportion of this ingredient varies with the size and age of the tree, the part from which the bark is derived, and even the season when it is gathered. It is most abundant in the young bark; and the English oak is said to yield four times as much in spring as in winter. Sir H. Davy found the inner bark most abundant in tannin, the middle portion or cellular integument much less so, and the epidermis almost wholly destitute as well of this principle as of extractive.

Gerber has discovered, in European oak bark, a peculiar bitter principle upon which he has conferred the name of *quercin*. It is obtained by boiling the bark with water acidulated with one hundredth of sulphuric acid, adding first milk of lime until the sulphuric acid is removed, and then a solution of carbonate of potassa so long as a white precipitate is produced, filtering the liquor, evaporating to the consistence of a thin extract, adding alcohol, and finally evaporating the spirituous solution down to a small volume, and allowing it to rest for some days. Yellow crystals form, which may be obtained colourless by repeated crystallizations. Quercin thus obtained is in small white crystals, inodorous, very bitter, readily soluble in water, less so in alcohol containing water, insoluble in absolute alcohol, ether, and oil of turpentine, and without acid or alkaline reaction. (*Arch. der Pharm.*, xxxiv. 167.)

2. *Quercus tinctoria.* Willd. *Sp. Plant.* iv. 444; Michaux, *N. Am. Sylv.* i. 91. The *black oak* is one of our largest trees, frequently attaining the height of eighty or ninety feet. Its trunk is covered with a deeply furrowed bark, of a black or dark-brown colour. The leaves are ovate-oblong, pubescent, slightly sinuated, with oblong, obtuse, mucronate lobes. The fructification is biennial. The acorn is globose, flattened at top, and placed in a saucer-shaped cup.

Black-oak bark has a more bitter taste than that of the other species, and may be distinguished also by staining the saliva yellow when it is chewed. Its cellular integument contains a colouring principle, capable of being extracted by boiling water, to which it imparts a brownish-yellow colour, which is deepened by alkalies and rendered brighter by acids. Under the name of *quercitron*, large quantities of this bark, deprived of its epidermis and reduced to coarse powder, are sent from the United States to Europe, where it is used for dyeing wool and silk of a yellow colour. The colouring principle is called *quercitrin*, or, from its property of combining with salifiable bases, *quercitric acid*. When quite pure it is colourless, but becomes yellow by absorbing oxygen. It is sweetish, with a bitter after-taste, and is very soluble in water, alcohol, and ether. M. Preisser obtained it by precipitating the tannin of a decoction of the bark by means of gelatin, filtering the liquor, adding a very little hydrated oxide of lead, which produced a brown precipitate, decanting the golden-yellow liquid left, precipitating with an additional quantity of the hydrated oxide, and decomposing the resulting quercitrate of lead by hydrosulphuric acid. A colourless liquid re-

mained, which, evaporated in vacuo, yielded white needle-shaped crystals of pure quercitrin. (*Journ. de Pharm. et de Chim.*, v. 251.) Besides this principle, the bark contains also much tannin; but it is less used in tanning than the other barks, in consequence of the colour which it imparts to the leather.

Medical Properties and Uses. Oak bark is astringent and somewhat tonic. It has been given with advantage in intermittent fever, obstinate chronic diarrhœa, and certain forms of passive hemorrhage; but it is not much employed as an internal remedy. Externally applied it is often productive of benefit. The decoction may be advantageously used as a bath, particularly for children, when a combined tonic and astringent effect is desirable, and the stomach is not disposed to receive medicines kindly. It has been employed in this way in marasmus, scrofula, intermittent fevers, chronic diarrhœa, and cholera infantum. As an injection in leucorrhœa, a wash in prolapsus ani and hemorrhoidal affections, and as a gargle in slight inflammation of the fauces, attended with prolapsed uvula, the decoction is often highly useful. It has also been recommended as an injection into dropsical cysts. Reduced to powder and made into a poultice, the bark was recommended by the late Dr. Barton as an excellent application in cases of external gangrene and mortification; and the infusion obtained from tanners' vats has been used beneficially as a wash for flabby, ill-conditioned ulcers. The bark may be given internally in the form of powder, extract, or decoction. The dose of the powder is from thirty grains to a drachm, of the extract about half as much, of the decoction two fluidounces. (See *Decoctum Quercûs.*)

Black-oak bark is considered inferior to the white-oak bark as an internal remedy, in consequence of being more disposed to irritate the bowels.

Acorns, besides the bitter and astringent principles of the bark, contain also a peculiar saccharine matter, which is insusceptible of the vinous fermentation. (*Journ. de Pharm.*, 3e *sér.*, xx. 335.) They are sometimes used as a tonic or astringent; and a decoction made from roasted acorns has been long employed in Germany as a remedy in scrofula. Before roasting they should be deprived of their shells; and the cotyledons, according to Dausse, should lose, during the process, 140 parts of their weight out of 500. (*Pharm. Cent. Blatt.*, Oct. 9, 1850, p. 687.) From half an ounce to an ounce may be prepared as coffee, and the whole taken at breakfast with cream and sugar. (*Richter.*)

RANUNCULUS. *U. S. Secondary.*

Crowfoot.

The cormus and herb of Ranunculus bulbosus. *U. S.*

Ranunculus. *Sex. Syst.* Polyandria Polygynia.—*Nat. Ord.* Ranunculaceæ.

Gen. Ch. Calyx five-leaved. *Petals* five, having the inner side of each claw furnished with a melliferous pore. *Seeds* naked, numerous. *Nuttall.*

Most of the plants belonging to this genus have the same acrid properties. Several of them grow together in our fields and pastures, and, from their close resemblance, are confounded under the common name of *butter-cup*, applied to them from the colour and shape of their flowers. Those which are most abundant are believed to have been introduced from Europe. Such are *R. bulbosus*, *R. acris*, and *R. repens*, which, with *R. sceleratus*, may be indiscriminately used. In Europe, *R. sceleratus* appears to have attracted most attention; in this country, *R. bulbosus*. The latter is the only one designated by our Pharmacopœia. *R. acris* and *R. Flammula* were formerly directed by the Dublin College, but were discarded from their Pharmacopœia at the last revision.

Ranunculus bulbosus. Willd. *Sp. Plant.* ii. 1324; Bigelow, *Am. Med. Bot.* iii. 60. This species of crowfoot is perennial, with a solid, fleshy root (cormus),

which sends up annually several erect, round, and branching stems, from nine to eighteen inches high. The radical leaves, which stand on long footstalks, are ternate or quinate, with lobed and dentate leaflets. The leaves of the stem are sessile and ternate, the upper more simple. Each stem supports several solitary, bright-yellow, glossy flowers, upon furrowed, angular peduncles. The leaves of the calyx are reflexed, or bent downwards against the flowerstalk. The petals are obcordate, and arranged so as to represent a small cup in shape. At the inside of the claw of each petal is a small cavity, which is covered with a minute wedge-shaped emarginate scale. The fruit consists of numerous naked seeds, in a spherical head. The stem, leaves, peduncles, and calyx are hairy.

In the months of May and June our pastures are everywhere adorned with the rich yellow flowers of this species of Ranunculus. Somewhat later *R. acris* and *R. repens* begin to bloom, and a succession of similar flowers is maintained till September. The two latter species prefer a moister ground, and are found most abundantly in meadows. *R. sceleratus* is found in ponds and ditches. In all these species, the whole plant is pervaded by a volatile acrid principle, which is dissipated by drying or by heat, and may be separated by distillation. Dr. Bigelow found that water distilled from the fresh plant had an acrid taste, and produced when swallowed a burning sensation in the stomach; and that it retained these properties for a long time, if kept in closely stopped bottles. The plant itself, when chewed, excites violent irritation in the mouth and throat; inflaming and even excoriating the tongue and inside of the cheeks and lips, if not quickly discharged. Both the root and herb of *R. bulbosus* are officinal.

Medical Properties and Uses. Crowfoot, when swallowed in the fresh state, produces heat and pain in the stomach, and, if the quantity be considerable, may excite fatal inflammation. It is, however, never used internally; though the juice and distilled water of some species of Ranunculus are said to act as a prompt and powerful emetic. The property for which it has attracted the attention of physicians is that of inflaming and vesicating the skin; and, before the introduction of the Spanish fly into use, it was much employed for this purpose. But the uncertainty and occasional violence of its action have nearly banished it from regular practice. While on some individuals it appears to produce scarcely any effect, on others it acts very speedily, exciting extensive and troublesome inflammation, which sometimes terminates in deep and obstinate ulcers. It probably varies in strength with the season; and, in the dried state, or boiled with water, is wholly inert. The decoction, moreover, is inert in consequence of the escape of the acrid principle. Nevertheless, the plant has been very properly retained in the Pharmacopœia, in the catalogue of medicines of secondary importance; as occasions may occur when the practitioner in the country may find advantage in having recourse to its powerful rubefacient and epispastic operation. W.

RESINA. *U. S., Lond., Ed., Dub.*

Resin.

The residuum after the distillation of the volatile oil from the turpentine of Pinus palustris and other species of Pinus. *U. S.* The residue of turpentine after the oil has been distilled. *Lond.* Residue of the distillation of the turpentines of various species of Pinus and Abies. *Ed.* Resin from the turpentine of Pinus sylvestris. *Dub.*

Resine blanche, Resine jaune, *Fr.;* Fichtenharz, *Germ.;* Ragea di pino, *Ital.;* Resina de pino, *Span.*

After the distillation of the volatile oil from the turpentines (see *Terebinthina*), a resinous matter remains, which on the continent of Europe is called *colophony*,

but in our language is commonly known by the name of *rosin*. It is the RESINA of the U. S. and British Pharmacopœias. It is sometimes called *resina flava* or *yellow resin*. When this, in a state of fusion, is strongly agitated with water, it acquires a distinct appearance, and is now denominated *resina alba* or *white resin*. Before describing this officinal substance, it may be proper to enumerate the characteristic properties of the proximate principles denominated resins.

Resins are solid, brittle, of a smooth and shining fracture, and generally of a yellowish colour and semitransparent. When perfectly pure, they are probably inodorous and often insipid; but, as usually found, they have a slight odour, and a somewhat acrid or bitterish taste. Their sp. gr. varies from 0·92 to 1·2. They are fusible by a moderate heat, decomposed at a higher temperature, and in the open air take fire, burning with a yellow flame and much smoke. Insoluble in water, they are dissolved by ether and the volatile oils, and generally by alcohol; and their alcoholic and ethereal solutions afford precipitates upon the addition of water. With pure potassa and soda they unite to form soaps, which are soluble in water; and the same result takes place when they are heated with solutions of the alkaline carbonates. Concentrated sulphuric acid dissolves them with mutual decomposition; and nitric acid converts them into artificial tannin. They readily unite by fusion with wax and the fixed oils.

Common or *yellow resin*, in its purest state, is beautifully clear and pellucid, but much less so as commonly found in the shops. Its odour and taste are usually in a slight degree terebinthinate; its colour yellowish-brown with a tinge of olive, and more or less dark according to its purity, and the degree of heat to which it has been exposed in its preparation. Sometimes it is almost black. It is rather heavier than water. At 276° F. it fuses, is completely liquid at 306°, begins to emit bubbles of gas at 316°, and is entirely decomposed at a red heat. Its ultimate constituents are carbon, hydrogen, and oxygen, in variable proportions. It appears, from the researches of Unverdorben, to contain three distinct resinous bodies, two of which, denominated *pinic* and *sylvic acids*, pre-existed in the turpentine, and the third, called *colophonic acid*, is formed by the agency of the heat in the process of distillation. The *pinic acid* is dissolved by cold spirit of the sp. gr. 0·865, and is thus separated from the sylvic acid. It is obtained pure by adding to the solution a spirituous solution of acetate of copper, dissolving the precipitated pinate of copper in strong boiling alcohol, decomposing this salt with a little muriatic acid, and adding water, which throws down the pinic acid in the form of a resinous powder. The *sylvic acid* is obtained by treating the residue of the common resin with boiling spirit of 0·865, which dissolves it, and lets it fall upon cooling. Both of these resinous acids are colourless. Pinic acid is soluble in weak cold alcohol; sylvic acid is insoluble in the same menstruum when cold, but is dissolved by it when boiling hot, and by strong alcohol at all temperatures. The salts which they form with the alkalies are soluble, those with the earths and metallic oxides, insoluble in water. *Colophonic acid* differs from the others in having stronger acid properties, and in being less soluble in alcohol. It is of a brown colour; and common resin is more or less coloured in proportion to the quantity of this acid which it contains. (*Kane's Chemistry.*) The experiments of Unverdorben were made with European colophony. It is somewhat uncertain whether exactly the same results would be afforded by the common resin of this country, which is obtained from a different species of pine. By the destructive distillation of resin an oleaginous product is obtained, called *resin oil*, which in various degrees of purity is employed in currying leather, lubricating machinery, preparing printers' ink, &c.

White resin differs from the preceding only in being opaque and of a whitish colour. These properties it owes to the water with which it is incorporated, and which gradually escapes upon exposure, leaving it more or less transparent.

Medical Uses. Resin is important as an ingredient of ointments and plasters, but is never used internally. According to Professor Olmsted, it has the property of preventing the oxidation of fatty substances, and thus contributes to the preservation of ointments. (*Am. Journ. of Pharm.*, xxii. 325.)

Rhamnus. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Rhamnaceæ.

Gen. Ch. Calyx tubular. *Corolla* scales defending the stamens, inserted into the calyx. *Berry. Willd.*

Rhamnus catharticus. Willd. *Sp. Plant.* i. 1092; Woodv. *Med. Bot.* p. 594, t. 210. The purging buckthorn is a shrub seven or eight feet high, with branches terminating in a sharp spine. The leaves are in fascicles, on short footstalks, ovate, serrate, veined. The flowers are usually diœcious, in clusters, small, greenish, peduncled, with a four-cleft calyx, and four very small scale-like petals, placed in the male flower, behind the stamens, which equal them in number. The fruit is a four-seeded berry.

The shrub is a native of Europe, and is said to have been found growing wild in this country. It was first discovered in the Highlands of New York by Dr. Barratt. (*Eaton's Manual.*) It flowers in May and June, and ripens its fruit in the latter part of September. The berries and their juice are officinal. When ripe they are about the size of a pea, round, somewhat flattened on the summit, black, smooth, shining, with four seeds, surrounded by a green, juicy parenchyma. Their odour is unpleasant, their taste bitterish, acrid, and nauseous. The expressed juice has the colour, odour, and taste of the parenchyma. It is reddened by the acids, and from deep-green is rendered light-green by the alkalies. Upon standing it soon begins to ferment, and becomes red in consequence of the formation of acetic acid. Evaporated to dryness, with the addition of lime or an alkali, it forms the colour called by painters *sap green.* The dried fruit of another species, *R. infectorius,* yields a rich yellow colour, for which it is much employed in the arts under the name of *French berries.*

Vogel obtained from the juice of the berries a peculiar colouring matter, acetic acid, mucilage, sugar, and a nitrogenous substance. Hubert found green colouring matter, acetic and malic acids, brown gummy matter, and a bitter substance which he considered as the purgative principle. M. Fleury obtained a peculiar crystallizable principle, which is contained both in the expressed juice and the residue remaining after expression, and for which he proposed the name of *rhamnin;* but he did not ascertain whether it possessed cathartic properties. (See *Journ. de Pharm.*, xxvii. 666.) Winckler obtained from the ripe fruit a

principle which he called *cathartin*, and believes that the rhamnin of Fleury, which was obtained from the unripe berries, is converted into that principle and grape sugar as the fruit matures. (*Chem. Gaz.*, viii. 232.) The *cathartin* of Winckler, which must not be confounded with the substance of the same name at one time supposed to be the purgative principle of senna, may be produced by evaporating the expressed juice of the berries to the consistence of syrup, treating this repeatedly with boiling absolute alcohol till it ceased to yield bitterness to the menstruum, mixing the tinctures, allowing the liquor to become cold, filtering, adding a large excess of ether, allowing the mixed liquids to stand, then filtering, evaporating in a water-bath, and repeating the process with the residue. The cathartin thus obtained is a pale-yellow powder, very bitter, soluble in water and alcohol but not in ether, and actively cathartic in a dose of from one to three grains. (See *N. Y. Journ. of Pharm.*, April, 1853, and *Am. Journ. of Pharm.*, xxv. 526.)

Medical Properties and Uses. Both the berries and the expressed juice are actively purgative; but, as they are apt to occasion nausea and severe griping, with much thirst and dryness of the mouth and throat, they are now little employed. They formerly enjoyed considerable reputation as a hydragogue cathartic in dropsy; and were given also in rheumatism and gout. The only shape in which they are used in this country is that of the syrup, which is sometimes, though rarely, added to hydragogue or diuretic mixtures. (See *Syrupus Rhamni.*) The dose of the recent berries is about a scruple, of the dried a drachm, and of the expressed juice a fluidounce.

Under the name of *cortex frangulæ*, the bark of *Rhamnus Frangula* is sometimes used in Germany as a cathartic. Buchner found in this bark a peculiar yellow volatile colouring principle which he called *rhamnoxanthin;* and which may be obtained by subjecting the alcoholic and ethereal extract to distillation. (*Journ. de Pharm.*, 3*e sér.*, xxiv. 293.)

RHEUM. *U. S., Lond., Ed., Dub.*

Rhubarb.

The root of Rheum palmatum, and other species of Rheum. *U. S.* Root of an undetermined species of Rheum. *Ed., Lond., Dub.*

Rhabarbarum; Rhubarbe, *Fr.;* Rhabarber, *Germ.;* Rabarbaro, *Ital.;* Ruibarbo, *Span.;* Hai-houng, *Chinese;* Schara-modo, *Thibet.*

Rheum. *Sex. Syst.* Enneandria Trigynia.—*Nat. Ord.* Polygonaceæ.

Gen. Ch. Calyx petaloid, six-parted, withering. *Stamens* about nine, inserted into the base of the calyx. *Styles* three, reflexed. *Stigmas* peltate, entire. *Achenium* three-cornered, winged, with the withered calyx at the base. *Embryo* in the centre of the albumen. (*Lindley.*)

Notwithstanding the length of time that rhubarb has been in use, it has not yet been determined from what precise plant the Asiatic drug is derived. The remoteness of the region where it is collected, and the jealous care with which the monopoly of the trade is guarded, have prevented any accurate information on the subject. All that we certainly know is that it is the root of one or more species of Rheum. The U. S. Pharmacopœia refers it to *R. Palmatum*, with other species not designated. The British Colleges recognise at present no particular species.

The terms *rha* and *rheon*, from the former of which were derived the names *rhabarbarum* and *rhubarb*, and from the latter the botanical title *Rheum*, were applied by the ancients to a root which came from beyond the Bosphorus, and which is supposed, though upon somewhat uncertain grounds, to have been the

product of the *Rheum Rhaponticum*, growing on the banks of the Caspian Sea and the Wolga. This species was also at one time believed to be the source of the medicine now in use; but the true rhubarb has long been known to be wholly distinct from the Rhapontic, and derived from a different source. It was not till the year 1732 that any probable information was obtained as to its real origin. At that time plants were received from Russia by Jussieu in France, and Rand in England, which were said to be of the species which afforded the genuine rhubarb, and were named by Linnæus, under this impression, *Rheum Rhabarbarum*, a title which has since given way to *Rheum undulatum*. At a subsequent period, Kauw Boerhaave obtained from a merchant, who dealt in the rhubarb of Tartary, some seeds which he said were those of the plant which produced the root he sold. These seeds, having been planted, yielded two species of Rheum, *R. undulatum*, and another which Linnæus named *R. palmatum*. Seeds transmitted by Dr. Mounsey from St. Petersburg to Dr. Hope, and planted in the botanic garden at Edinburgh, produced the latter species; and the same was also raised at Upsal from a root received by Linnæus from De Gorter, and was described A. D. 1767 by the younger Linnæus, two years after the appearance of Dr. Hope's paper in the Philosophical Transactions. Thus far the evidence appears equally in favour of *R. palmatum* and *R. undulatum*. The claims of another species were afterwards presented. Pallas, upon exhibiting the leaves of *R. palmatum* to some Bucharian merchants of whom he was making inquiries relative to the rhubarb plant, was told that the leaves of the latter were entirely different in shape; and the description he received of them corresponded more closely with those of *R. compactum*, than of any other known species. Seeds of this plant were, moreover, sent to Miller from St. Petersburg, as those of the true Tartarian rhubarb. A few years since the attention of naturalists was called to a fourth species, for which the same honour has been claimed. Dr. Wallich, superintendent of the botanical garden at Calcutta, received seeds which were said to be those of the plant which yielded the Chinese rhubarb, growing on the Himalaya mountains and the highlands of Tartary. These produced a species not previously described, which Dr. Wallich named *R. Emodi*, from the native title of the plant. It is the *R. australe* of Mr. Don and of Colebrooke, and has been ascertained to afford a root which, though purgative, is very unlike the officinal rhubarb. Other species have been found to grow in the Himalaya mountains, from which a kind of rhubarb used by the natives is said to be procured; but none of it reaches the markets of this country or Europe. From what has been said, it is obvious that no species yet mentioned can be considered as the undoubted source of commercial rhubarb; the plant having, in no instance, been seen and examined by naturalists in its native place. Sievers, an apothecary, sent to Siberia in the reign of Catharine II., with the view of improving the cultivation of the native rhubarb, asserts from the information given him by the Bucharians, that all the seeds procured under the name of true rhubarb are false, and pronounces "all the descriptions in the Materia Medicas to be incorrect." This assertion, however, has no relation to *R. australe* which has been subsequently described; but it is said that the roots of that plant, dried by the medical officers of the British army, differ from true rhubarb in appearance and power.

All the plants of this genus are perennial and herbaceous, with large branching roots, which send forth vigorous stems from four to eight feet or more in height, surrounded at their base with numerous very large petiolate leaves, and terminating in lengthened branching panicles, composed of small and very numerous flowers, resembling those of the Rumex or dock. There is some difficulty in arranging the species, in consequence of the tendency of the cultivated plants to form hybrids; and it is frequently impossible to ascertain to which of the wild

types the several garden varieties are to be referred. The following descriptions are from the *Flora Medica* of Dr. Lindley.

Rheum palmatum. Willd. *Sp. Plant.* ii. 489; Lindley, *Flor. Med.* p. 358; Carson, *Illust. of Med. Bot.* ii. 22, pl. 69. "Leaves roundish-cordate, half palmate; the lobes pinnatifid, acuminate, deep dull-green, not wavy, but uneven and very much wrinkled on the upper side, hardly scabrous at the edge, minutely downy on the under side; sinus completely closed; the lobes of the leaf standing forwards beyond it. Petiole pale green, marked with short purple lines, terete, obscurely channeled quite at the upper end. Flowering stems taller than those of any other species." This species is said to inhabit China in the vicinity of the great wall. It has been cultivated in England and France for the sake of its root, which is generally admitted to approach more nearly in odour, taste, and the arrangement of its colours, than that of any other known species, to the Asiatic rhubarb.

R. undulatum. Willd. *Sp. Plant.* ii. 489; Lindley, *Flor. Med.* p. 357; Woodv. *Med. Bot.* 3d ed. v. 81. "Leaves oval, obtuse, extremely wavy, deep-green, with veins purple at the base, often shorter than the petiole, distinctly and copiously downy on each side, looking as if frosted when young, scabrous at the edge; sinus open, wedge-shaped, with the lower lobes of the leaves turned upwards. Petiole downy, blood-red, semi-cylindrical, with elevated edges to the upper side, which is narrower at the upper than the lower end." This is a native of Siberia, and probably of Tartary and China. It was cultivated by the Russian government as the true rhubarb plant; but the culture has been abandoned. It contributes to the rhubarb produced in France.

R. compactum. Willd. *Sp. Plant.* ii. 489; Lindley, *Flor. Med.* p. 358; Carson, *Illust. of Med. Bot.* ii. 24, pl. 71. "Leaves heart-shaped, obtuse, very wavy, deep-green, of a thick texture, scabrous at the margin, quite smooth on both sides, glossy and even on the upper side; sinus nearly closed by the parenchyma. Petiole green, hardly tinged with red except at the base, semi-cylindrical, a little compressed at the sides, with the upper side broad, flat, bordered by elevated edges, and of equal breadth at each end." This plant is said to be a native of Tartary and China. It is one of the garden rhubarbs, and is cultivated in France for its root.

R. australe. Don, *Prod. Flor. Nepal.* p. 75. — *R. Emodi.* Wallich; Lindley, *Flor. Med.* p. 354; Carson, *Illust. of Med. Bot.* ii. 24, pl. 70. "Leaves cordate, acute, dull-green, but little wavy, flattish, very much wrinkled, distinctly rough, with coarse short hairs on each side; sinus of the base distinctly open, not wedge-shaped but diverging at an obtuse angle, with the lobes nearly turned upwards. Petioles very rough, rounded-angular, furrowed; with the upper side depressed, bordered by an elevated edge, and very much narrower at the upper than the lower end." The root of this species was at one time conjectured to be the source of officinal Asiatic rhubarb; but has been found to have scarcely any resemblance to it. The plant has been cultivated both in Europe and this country, and its petioles answer well for tarts, &c.

R. Rhaponticum. Willd. *Sp. Plant.* ii. 488; Lindley, *Flor. Med.* p. 357; Loudon's *Encyc. of Plants*, p. 335. "Leaves roundish-ovate, cordate, obtuse, pale-green, but little wavy, very concave, even, very slightly downy on the under side, especially near the edge, and on the edge itself; scabrous at the margin; sinus quite open, large, and cuneate. Petiole depressed, channeled on the upper side, with the edges regularly rounded off, pale green, striated, scarcely scabrous. Panicles very compact and short, always rounded at the ends, and never lax as in the other garden species. Flowering stem about three feet high." The Rhapontic rhubarb grows upon the banks of the Caspian Sea, in the deserts between the Wolga and the Oural, and in Siberia. It is said also to grow upon

the borders of the Euxine. It is cultivated as a garden plant in Europe and this country; and large quantities of the root are produced for sale in France. It is said by Royle to be the source of the English rhubarb.

Besides the species above described, *R. leucorrhizum*, growing in the Kirghese desert in Tartary, *R. Caspicum* from the Altaï mountains, *R. Webbianum*, *R. speciforme*, and *R. Moorcraftianum*, natives of the Himalaya mountains, and *R. crassinervium* and *R. hybridum*, cultivated in Europe, but of unknown origin, yield roots which have either been employed as purgatives, or possess properties more or less analogous to those of officinal rhubarb, though they have not entered into general commerce.

The leafstalks of the different species of Rheum have a pleasant acid taste, and are used for making tarts and pies, which are not unlike those made with gooseberries. It is for this purpose only that the plants are cultivated in the United States. Lindley states that R. Rhaponticum, R. hybridum, and R. compactum, and hybrid varieties of them, are the common garden rhubarbs.

In relation to the culture and preparation of rhubarb, our information is almost as uncertain as on the subject of its natural history. The accounts received from the Bucharian merchants are very discordant, and few intelligent travellers have penetrated into the country where the medicine is collected. We shall present, however, a brief abstract of what we have been able to collect upon the subject from the authorities we have consulted.

Rhubarb is produced abundantly in the elevated lands of Tartary, about the lake Koko Norr, and is said to be cultivated in the neighbouring Chinese province of Shen-see, and in that of Setchuen. From these sources it is generally supposed that our supplies of Russian and Chinese rhubarb are exclusively derived; but the root is also collected in Boutan and Thibet, on the north of the Himalaya mountains; and it is probable that the plant pervades the whole of Chinese Tartary. It flourishes best in a light sandy soil. We are told by Mr. Bell, who, on a journey from St. Petersburg to Pekin, had an opportunity of observing it in a growing state, that it is not cultivated by the Tartars, but springs up spontaneously in tufts at uncertain distances, wherever the seeds have fallen upon the heaps of loose earth thrown up by the marmots. In other places the thickness of the grass prevents their access to the soil. The root is not considered sufficiently mature for collection till it has attained the age of six years. It is dug up twice a year in Tartary, in the spring and autumn; in China not till the winter. After removal from the ground, it is cleaned, deprived of its cortical portion and of the smaller branches, and then divided into pieces of a convenient size. These are bored with holes, and strung upon cords to dry, according to Mr. Bell, about the tents and on the horns of sheep; according to Sievers, under sheds, by which the rays of the sun are excluded, while the air has free access. The Chinese are said first to place the pieces on a stone slab heated by fire beneath, and afterwards to complete the drying process by exposing them to the sun and air. In Boutan the roots are hung up in a kind of drying room, in which a moderate and regular heat is maintained. Much time and attention are devoted to the preparation of the root; and Sievers states that a year sometimes elapses from the period of its collection, before it is ready for exportation. A very large proportion of its weight is lost in drying, according to some accounts four-fifths, to others not less than seven-eighths. It is probably in order to favour the drying that the bark is removed. The trade in rhubarb is said to centre in the Chinese town of Si-nin, where a Bucharian company or family is established, which possesses a monopoly of this trade, in consideration of a certain tribute paid to the government. To this city the rhubarb is brought from the various places of its collection, and, having been duly assorted, and undergone further preparation, is transmitted partly to Russia, partly to the coast of China; so that the drug which reaches

us through St. Petersburg is procured from the same neighbourhood with that imported from Canton. But it will soon be seen that there are differences between the Russian and Chinese rhubarb, which would seem to indicate a different origin, and might authorize doubts as to the entire accuracy of the above accounts. It is at least probable that the drug produced in the province of Setchuen, whence the best China rhubarb is said to be brought, takes a more direct route to the coast than that through the town of Si-nin. Besides the two commercial varieties just mentioned, a third occasionally comes to us from Europe, where the cultivation of rhubarb has been carried on for some time with success, especially in France, Belgium, and Great Britain. Of these three varieties we shall treat under different heads.

1. *Chinese Rhubarb.*

India Rhubarb. Rheum Sinense vel *Indicum.* Much the largest proportion of rhubarb consumed in this country is brought from Canton. Though somewhat inferior to the Russian, its comparative cheapness gives it a decided preference in our markets; and, when of good quality, it does not disappoint the expectations of the physician.

It is in cylindrical or roundish pieces, sometimes flattened on one or both sides, of a dirty brownish-yellow colour externally, appearing as if the cortical portion of the root had been removed by scraping, and the surface rendered smooth and somewhat powdery by attrition. The best pieces are heavier than the Russian rhubarb, have a texture rather close and compact, and when broken present a ragged uneven surface, variegated with intermingled shades of dull-red, yellowish, and white, which are sometimes diversified or interrupted by darker colours. The pieces are generally perforated with small holes, intended for convenience of suspension during the drying process; and portions of the suspending cord are not unfrequently found remaining in the holes. Chinese rhubarb has a peculiar somewhat aromatic smell, and a bitter astringent taste, is gritty when chewed, imparts a yellow colour to the saliva, and affords a yellowish powder with a reddish-brown tinge. With the pieces of good quality others often come mingled, which are defective from decay or improper preparation. These are usually lighter, and of a dark or russet colour. Like all the other varieties of rhubarb, this is liable to be attacked by worms; and in almost every large parcel pieces may be found which have suffered from this cause. The want of proper care in its selection by the Chinese merchants, and the exposure incident to a long sea-voyage, are causes which contribute to its inferiority to the Russian rhubarb. As the whole contents of the chest imported are usually powdered together, including the worst as well as the best pieces, it follows that the powder is inferior in efficacy to the selected and sound pieces.

In former editions of this work, we have noticed a variety of rhubarb imported from Canton, which was evidently prepared, before leaving China, so as to resemble the Russian, having an angular surface as if pared with a knife. The pieces were obviously selected with great care, as they were remarkably free from defects. But in most of those which came under our notice, the small penetrating hole was observable, which characterizes the Chinese rhubarb, though it had in some instances been filled with the powdered root, so as in some measure to conceal it. Besides, the colours were not quite so bright as those of Russia rhubarb. This is undoubtedly the variety described by Pereira, under a distinct head, as the *Dutch-trimmed* or *Batavian rhubarb,* and considered by him as probably Bucharian or Russian rhubarb of inferior quality, sent by the way of Canton. A sufficient proof, we think, that this is not the case, is the presence in most pieces of the small penetrating hole, occasionally filled with remains of the cord, and

in some pieces almost shaved away in the paring process. We have never seen such a hole in any piece of true Russian rhubarb, which does not appear to be strung up like the Chinese when dried.

Under the title of *Canton stick rhubarb*, Pereira describes a variety of which small quantities have been imported from Canton into London. It bears much resemblance to the English stick rhubarb, and is supposed to be derived from the branches of the root of the plant which yields the true Chinese rhubarb.

2. *Russian Rhubarb.*

Turkey Rhubarb. Bucharian Rhubarb. Rheum Russicum vel *Turcicum.* The rhubarb taken to Russia from Tartary undergoes a peculiar preparation, in conformity with the stipulations of a contract with the Bucharian merchants who furnish the supply. The best is selected, and each piece perforated in order to ascertain whether it is sound in the centre. From Si-nin it is conveyed by the Bucharian merchants to the frontier town of Kiachta, where it undergoes a rigid inspection by an apothecary stationed at that place by the Russian government. All those pieces which do not pass examination are committed to the flames; and the remainder is sent to St. Petersburg. This variety is sometimes called *Turkey rhubarb*, from the circumstance that it was formerly derived from the Turkish ports, whither it is said to have been brought from Tartary by caravans through Persia and Natolia. The circumstance of the identity of the Russian and Turkey rhubarb, and their decided difference from the Chinese, would appear to indicate a distinct origin for the two varieties. Inferior parcels of the root, which will not pass the inspection of the Russian authorities, are said to enter Russia by Taschkent, and to be known to the druggists of that country by the name of *Taschkent rhubarb.*

The pieces of Russian rhubarb are irregular and somewhat angular, appearing as if the bark had been shaved off longitudinally by successive strokes of a knife, and a portion of the interior substance removed with each shaving. They have a cleaner and fresher appearance than the Chinese, and their colour both internally and externally, though of the same general character, is somewhat more lively. They are less compact and heavy; and are cut with less facility, owing to their giving away before the knife. Another distinction is the character of the perforations, which in the Russian rhubarb are large, frequently reaching only to the centre, and evidently made for the purpose of inspection; while in the Chinese they are small, penetrate completely through the pieces, and were intended for the passage of a suspending cord. The taste and smell of the former closely resemble those of the latter, except that the Russian is rather more aromatic. There is the same crackling under the teeth, and the same yellow stain imparted to the saliva; but the colour of the powder in this variety is a bright yellow, without the brownish tinge exhibited by the Chinese. When thin slices, previously boiled in water, are examined by the microscope, they exhibit numerous clusters of minute crystals of oxalate of lime. Mr. Quekett found between 35 and 40 grains of them in 100 grains of the root. They are observed both in the Russian and Chinese rhubarb.

The care which renders the Russian rhubarb so free from defects, tends greatly to enhance its price, and consequently to limit its consumption. Its great comparative value in the market has led to frequent attempts at adulteration; and the pieces of Chinese rhubarb are sometimes cut down and prepared so as to resemble the Russian. The fraud, however, may be detected by adverting to the peculiarities in texture, colour, and weight, by which the varieties are distinguished, and to the occasional presence of the small penetrating hole or vestiges of it. We have seen a specimen in which the hole was enlarged at its two

extremities, and closed by powder in the middle, with the view of imitating the larger perforations of the Russian pieces. Sometimes the worm-eaten pieces are made to resemble the sound, by filling up the holes with a mixture of pulverized rhubarb and mucilage, and covering over the surface with the powder. By removing this, the fraud is at once revealed.

3. *European Rhubarb.*

In various parts of Europe, particularly in England, France, Belgium, and Germany, the rhubarb plants have been cultivated for many years; and considerable quantities of the root are annually brought into the market. It is imported into this country from England and France.

English Rhubarb. This formerly came in two forms. In one the root was cut and perforated in imitation of the Russian. The pieces were of various shape and size, sometimes cylindrical, but more commonly flat, or somewhat lenticular, and of considerable dimensions. We have for a long time seen none of this variety in our markets. In the other, the pieces are somewhat cylindrical, five or six inches long by an inch or less in thickness, and more or less irregular upon the surface, as if they had shrunk unequally in drying. This is called *stick rhubarb* in England, and is still occasionally met with in our shops. English rhubarb is lighter than the Asiatic, more spongy, and often somewhat pasty under the pestle. It is of a redder colour, and when broken exhibits a more compact and regular marbling; the pinkish lines being arranged in a radiated manner from the centre towards the circumference. The powder also has a deeper reddish tint. The odour is feeble and less aromatic than that of the Asiatic varieties; the taste is astringent and mucilaginous with little bitterness; and the root, when chewed, scarcely feels gritty between the teeth, and but slightly colours the saliva. Few crystals of oxalate of lime are discoverable by means of the microscope. Most of the commercial English rhubarb is now cultivated near Banbury, and is said to be the product of R. Rhaponticum.

French Rhubarb. Rhapontic Rhubarb. Krimea Rhubarb. The rhubarb produced in France is at present, according to Guibourt, chiefly from *R. Rhaponticum*, *R. undulatum*, and *R. compactum;* that of *R. palmatum*, which most closely resembles the Asiatic, having been found to degenerate so much, as not to be a profitable object of culture. Most of the French rhubarb is produced in the neighbourhood of L'Orient, in the department of Morbihan; and the spot where it grows has, from this circumstance, received the name of *Rheum-pole.* Two kinds are described by Guibourt, both under the name of *Rhapontic root.* One proceeds from the R. Rhaponticum, growing in the gardens in the environs of Paris; the other, from this and the two other species above mentioned, cultivated at Rheumpole. The former is in pieces of the size of the fist or smaller, ligneous in their appearance, of a reddish-gray colour on the outside, internally marbled with red and white arranged in the form of crowded rays proceeding from the centre to the circumference, of an odour like that of Asiatic rhubarb, but more disagreeable, of a mucilaginous and very astringent taste, not crackling under the teeth, but tinging the saliva yellow, and affording a reddish-yellow powder. The pieces of the latter are irregularly cylindrical, three or four inches long, and from one to two or even three inches thick, less ligneous in appearance than the preceding, and externally of a pale or brownish-yellow colour less inclining to redness. In exterior aspect, this variety bears considerable resemblance to Chinese rhubarb; but may be distinguished by its more disagreeable odour, its astringent and mucilaginous taste, its want of crackling under the teeth, and its radiating fracture, in which properties it is similar to the preceding variety. Considerable quantities of this drug have been imported into

the United States from France, under the name of *Krimea rhubarb;* and it is sometimes employed, we fear, to adulterate the powder of the Chinese rhubarb. It appears to have displaced in France the *Rhapontic root* formerly imported from the Euxine. Whether from difference in species, or from the influence of soil and climate, none of the European rhubarb equals the Asiatic in purgative power.*

Choice of Rhubarb. In selecting good rhubarb, without reference to the commercial variety, those pieces should be preferred which are moderately heavy and compact, of a lively colour, brittle, presenting when broken a fresh appearance, with reddish and yellowish veins intermingled with white, of an odour decidedly aromatic, of a bitter and astringent not mucilaginous taste, feeling gritty and staining the saliva yellow when chewed, and affording a powder either bright yellow, or yellow with but a slight reddish-brown tinge. When very light, rhubarb is usually rotten or worm-eaten; when very heavy and compact, it is of inferior species, culture, or preparation. Rotten, worm-eaten, or otherwise inferior rhubarb, is often powdered and coloured yellow with turmeric; and the shavings left when Chinese rhubarb is trimmed for powdering, or to imitate the Russian, are applied to the same purpose.

Chemical Properties. Rhubarb yields all its active properties to water and alcohol. The infusion is of a dark reddish-yellow colour, with the taste and odour of rhubarb; and the residue, after sufficient maceration, is whitish, inodorous, and insipid. By long boiling the virtues of the medicine are impaired. Many attempts have been made to analyze the root, with various results. Among them, are those of the two Henrys and Caventou of Paris, Brande of London, Peretti of Rome, and Hornemann, Brandes, and Schlossberger and Döpping of Germany. Brandes found in 100 parts of Chinese rhubarb, 2 of pure *rhabarbaric acid*, 7·5 of the same acid impure, 2·5 of gallic acid, 9·0 of tannin, 3·5 of colouring extractive, 11·0 of uncrystallizable sugar with tannin, 4·0 of starch, 14·4 of gummy extractive, 4·0 of pectic acid, 1·1 of malate and gallate of lime, 11·0 of oxalate of lime, 1·5 of sulphate of potassa and chloride of potassium, 1·0 of silica, 0·5 of phosphate of lime and oxide of iron, 25·0 of lignin, and 2·0 of water. The most recent elaborate analysis which has come to our notice is that of Schlossberger and Döpping. Besides extractive, tannic and gallic acids, sugar, starch, pectin, lignin, oxalate of lime, and various inorganic salts, they discovered three colouring principles, holding an intermediate place between resin and extractive matter, being freely soluble in alcohol, and slightly soluble in water. Two of these were uncrystallizable, and denominated *brown resin* and *red resin*, or *phæoretin* and *erythroretin*, the other crystallizable in granular crystals, and identical with the *chrysophanic acid*, previously discovered by Rochleder and

* Besides the varieties of rhubarb above described, others are noticed by writers. Pallas speaks of a *white rhubarb*, brought to Kiachta by the Bucharian merchants who conveyed to that place the drug for Russian commerce. It was white as milk, of a sweet taste, and equal to the best rhubarb in quality. It is supposed to be the product of *R. leucorrhizum.* At present, however, it is unknown at St. Petersburg. The *Himalaya rhubarb* is produced by R. australe, and other species mentioned in the text as growing in the Himalaya mountains. According to Dr. Royle, it makes its way to the lower countries in Hindostan, where it sells for one-tenth of the price of the best rhubarb. Mr. Twining tried it in the Hospital at Calcutta, and found it superior as a tonic and astringent to Russian rhubarb, and nearly equal to it in purgative power. A variety known in Russia as *Bucharian rhubarb*, differing from the variety which we call Russian, and which is known in Russia as Chinese rhubarb, is imported into that country from Tartary, and reaches St. Petersburg by Nishny. Parcels of it are said also to reach Vienna, by the way of Brody in Gallicia. Still another variety is that called *Siberian rhubarb*, which is known in Russia by the name of *Siberian rhapontic root.* As these are inferior kinds, and probably never reach our markets, we have not thought it necessary to swell our pages with descriptions of them. The reader who wishes further information is referred to papers by Pereira, in the *London Pharmaceutical Journal*, republished in the *Am. Journ. of Pharm.*, xviii. 63, and 123.

Heldt in the yellow lichen, or Parmelia parietina of Sprengel. Another resinous substance was also obtained, which was named *aporetin;* but, as it was insoluble in the alcohol from which it had been precipitated by ether, and was isomeric with phæoretin, there is reason to think that it was a product of the operation. The three principles above referred to were obtained by exhausting rhubarb with alcohol, evaporating the tincture, exhausting the extract with water, dissolving the residue in the least possible quantity of alcohol, and treating this solution with ether. A precipitate was produced, a portion of which (aporetin) was insoluble in alcohol, and the remainder was obtained separate by solution in that fluid and evaporation. This was *phæoretin*. It is a yellowish-brown powder, very slightly soluble in water and ether, freely soluble in alcohol and in alkaline solutions, with which it produces an intense reddish-brown colour, and from which it is thrown down yellow by the mineral acids. The ethereal solution of the alcoholic extract, after all the aporetin and phæoretin had been separated, was allowed to evaporate spontaneously, and a large quantity of crystalline granules was obtained, of a beautiful yellow colour. These being washed with ether constituted the *chrysophanic acid*. When the ethereal solution showed no longer a disposition to deposit crystals, it was evaporated, and yielded a product having all the properties of the resins, and forming beautiful purple combinations with potassa and ammonia. This was the *erythroretin*, or red resin of rhubarb. The matter dissolved by water from the alcoholic extract was found to have the odour and taste of rhubarb in a high degree. In this no doubt was contained the peculiar active principle or principles of rhubarb; but Schlossberger and Döpping were not more successful than their predecessors in isolating it. They obtained a slightly bitter extractive matter; but it had not the flavour of rhubarb. (*Pharm. Journ. and Trans.*, iv. 136, 232, 318, and viii. 190.)

Many distinguished chemists have sought for the purgative ingredient of rhubarb, and some not without supposed success; but scarcely has the new principle been described and named, before the fallacy of its claim has been determined. The *caphopicrite* of Henry, the *rhabarbarin* of Pfaff and others, the *rheumin* of Hornemann, the *rhabarbaric acid* of Brandes, and, lastly, the *rhein* of Professor Dulk, have all been shown to be bodies more or less complex; and certainly no one of them can be admitted to be the peculiar purgative principle. The astringency of rhubarb, there can be no doubt, resides in its tannic acid. Some have supposed that the tonic and cathartic properties reside in different principles; but we are disposed to think, from the correspondence of the bitterness with the purgative property, that they reside in the same substance; and, from the fact that exposure to heat diminishes the cathartic power, there is reason to believe that this substance when isolated will prove to be more or less volatile.

Chrysophanic acid is at present one of the most interesting constituents. Most of the hitherto supposed active principles have been mixtures of this with other substances. The rhabarbaric acid of Brandes probably approaches nearest to it in character. When pure it is beautifully yellow, without smell and taste, disposed to an imperfect granular crystallization, almost insoluble in cold water, more soluble in hot water and in ether, but most freely so in alcohol. When heated it emits yellow vapours. Alkaline solutions dissolve it with the production of a beautiful red colour; but the solution with potassa, when evaporated, changes first to violet, and then to blue. It is probably the chief ingredient in the fine yellow colouring matter which is produced by the reaction of nitric acid on rhubarb, and which, in consequence of the magnificent purples which it produces with the alkalies, M. Garot has recently proposed, under the name of *erythrose*, to introduce into the arts as a dyestuff. (See *Journ. de Pharm. et de Chim.*, xvii. 5.)

There are other interesting principles in rhubarb. Some have been disposed to ascribe its odour to a volatile oil; but this has not been isolated. Tannic acid is an important constituent. It is of that variety which precipitates the salts of

sesquioxide of iron of a greenish colour. The oxalate of lime is interesting from its quantity, and from the circumstance that, existing in distinct crystals, it occasions the grittiness of the rhubarb between the teeth. The proportion seems to vary exceedingly in different specimens. According to Scheele and Henry, it constituted nearly one-third, and Quekett found, as already stated, between 35 and 40 per cent.; while Brandes obtained only 11, and Schrader only 4·5 parts in the hundred. Little or no difference of composition has been found between the Russian and Chinese rhubarb. The European contains but a small proportion of oxalate of lime, and is therefore less gritty when chewed. It has, however, more tannin and starch than the Asiatic.

When powdered rhubarb is heated, odorous yellow fumes rise, which are probably in part the vapour of chrysophanic acid. Its infusion is reddened by the alkalies, in consequence of their union with this acid, and their reaction on the other colouring principles. It yields precipitates with gelatin, most of the acids, the salts of sesquioxide of iron, acetate of lead, nitrate of protoxide of mercury, nitrate of silver, protochloride of tin, lime-water, and solutions of quinia. Nitric acid occasions at first a turbidness, and afterwards the deposition of a yellow precipitate. The substances producing precipitates may be considered as incompatible with the infusion.

Medical Properties and Uses. The medical properties of rhubarb are peculiar and valuable. Its most remarkable singularity is the union of a cathartic with an astringent power; the latter of which, however, does not interfere with the former, as the purgative effect precedes the astringent. It is also tonic and stomachic; invigorating, in small doses, the process of digestion. It is not probable that these properties reside in a single proximate principle; and, as rhubarb owes its chief value to their combination, it is not to be expected that chemical analysis will be productive of the same practical advantages in this, as in some other medicines, the virtues of which are concentrated in one ingredient. In its purgative operation rhubarb is moderate, producing fecal rather than watery discharges, and appearing to affect the muscular fibre more than the secretory vessels. It sometimes occasions griping pains. Its colouring principle is absorbed, and may be detected in the urine. By its long continued use, the perspiration, especially that of the axilla, is said to become yellow, and the milk of nurses to acquire a purgative property. It gives a yellow colour to the alvine discharges.

The circumstances of disease to which it is applicable may be inferred from its peculiar properties. When the stomach is enfeebled, or the bowels relaxed, at the same time that a gentle cathartic is required, rhubarb, as a general rule, is preferable to all others. Hence its use in dyspepsia attended with constipation, in diarrhœa when purging is indicated, in the secondary stages of cholera infantum, in chronic dysentery, and in almost all typhous diseases when fecal matter has accumulated in the intestines, or the use of cathartic medicine is necessary to prevent such accumulation. When employed in cases of habitual constipation, its astringent tendency should be counteracted by combining it with soap. Magnesia is also an excellent associate in disorders of the stomach and bowels. By combination with other cathartics, rhubarb frequently acquires additional activity, while it gives increased efficiency to the substance with which it is associated. A mixture of calomel and rhubarb is a brisk and powerful cathartic, much used in the commencement of our bilious fevers. As a general rule, rhubarb is not applicable to cases attended with much inflammatory action. Its griping effect may be counteracted by combining it with aromatics.

The dose of rhubarb as a purgative is from twenty to thirty grains, as a laxative and stomachic from five to ten grains. European rhubarb must be given in double or treble the dose to produce an equal effect. Few medicines are used in a greater variety of forms. It is most effectual in substance. It is frequently

given in the shape of pill, combined with an equal proportion of soap, when its laxative effect is desired. The infusion is much used in cases of delicate stomach, and is peculiarly adapted to children. The syrup and tincture are also highly useful preparations. They are all officinal.

By the roasting of rhubarb its cathartic property is diminished, probably by the volatilization of the purgative principle, while its astringency remains unaffected. This mode of treatment has, therefore, been sometimes resorted to in cases of diarrhœa. By long boiling the same effect is said to be produced.

Powdered rhubarb has been usefully applied to indolent and sloughing ulcers. It is said to have proved purgative when sprinkled over a large ulcerated surface; and the same effect is asserted to have been produced by rubbing it, mingled with saliva, over the abdomen.

PAPAVER. See OPIUM.

Papaver Rhœas. Willd. *Sp. Plant.* ii. 1146; Woodv. *Med. Bot.* p. 387, t. 139. The *red* or *corn poppy* is distinguished by its hairy stem, which is branched and rises about a foot in height, by its incised pinnatifid leaves, by its urn-shaped capsule, and by the full, bright, scarlet colour of its petals. It is a native of Europe, where it grows wild in great abundance, adorning especially the fields of grain with its brilliant flower. It has been introduced and naturalized in this country.

Its capsules contain the same kind of milky juice as that found in *P. somniferum*, and an extract has been prepared from them having the properties of opium; but the quantity is too small to repay the trouble of its preparation. M. Tilhoi has shown that the extract contains morphia, but in a proportion exceedingly minute compared with that in which it exists in opium. (*Journ. de Pharm. et de Chim.*, ii. 513.) The petals are the officinal portion. They have a narcotic smell, and a mucilaginous, slightly bitter taste. By drying, they lose their odour, and assume a violet-red colour. Chevalier detected a very minute proportion of morphia in an extract obtained from them; but their operation on the system is exceedingly feeble, and they are valued more for their beautiful scarlet colour, which they communicate to water, than for their medical virtues. According to Leo Meier, the colouring principles of the flowers are two acids, which he denominates *rhœadic* and *papaveric acids*. (See *Am. Journ. of Pharm.*, xviii. 211.) A syrup is prepared from them, which was formerly prescribed as an anodyne in catarrhal affections; but is now little esteemed, except for its colour.

RHUS GLABRUM. *U. S. Secondary.*

Sumach.

The fruit of Rhus glabrum. *U. S.*

RHUS. *Sex. Syst.* Pentandria Trigynia.—*Nat. Ord.* Anacardiaceæ.

Gen. Ch. Calyx five-parted. *Petals* five. *Berry* small, with one nuciform seed. *Nuttall.*

Of this genus there are several species which possess poisonous properties, and should be carefully distinguished from that here described. For an account of them the reader is referred to the article *Toxicodendron.*

Rhus glabrum. Willd. *Sp. Plant.* i. 1478. This species of Rhus, called variously *smooth sumach*, *Pennsylvania sumach*, and *upland sumach*, is an indigenous shrub from four to twelve feet high, with a stem usually more or less bent, and divided into straggling branches, covered with a smooth light-gray or somewhat reddish bark. The leaves are upon smooth petioles, and consist of many pairs of opposite leaflets, with an odd one at the extremity, all of which are lanceolate, acuminate, acutely serrate, glabrous, green on their upper surface, and whitish beneath. In the autumn their colour changes to a beautiful red. The flowers are greenish-red, and disposed in large, erect, terminal, compound thyrses, which are succeeded by clusters of small crimson berries covered with a silky down.

The shrub is found in almost all parts of the United States, growing in old neglected fields, along fences, and on the borders of woods. The flowers appear in July, and the fruit ripens in the early part of autumn. The bark and leaves are astringent, and said to be used in tanning leather and in dyeing. Mr. W. J. Watson found in the bark of the root, albumen, gum, starch, tannic and gallic acids, caoutchouc, resin, colouring matter, and evidences of volatile oil. (*Am. Journ. of Pharm.*, xxv. 194.) Excrescences are produced under the leaves resembling galls in character, and containing large quantities of tannic and gallic acids. These have been used as a substitute for the imported galls by Dr. Walters, of New York, who thought them, in every respect, preferable. They may be collected at little expense, as they are produced very abundantly, especially in the Western States. (*A. W. Ives's edition of Paris's Pharmacologia.*) The only officinal part of the plant is the berries.

These have a sour, astringent, not unpleasant taste, and are often eaten by the country people with impunity. According to Mr. Cozzens, of New York, the acid to which they owe their sourness is the malic, and is contained in the pubescence which covers their surface; as, when it is washed away by warm water, the berries are wholly free from acidity. Professor W. B. Rogers, of Virginia, found the acid combined with lime, in the state of bimalate.* Mr. W. J. Watson ascertained that free malic acid and bimalate of lime coexist in the berries, which contain also, upon the same authority, tannic and gallic acids, fixed oil, extractive, red colouring matter, and a little volatile oil.

Medical Properties and Uses. Sumach berries are astringent and refrigerant; and their infusion has been recommended as a cooling drink in febrile complaints, and a pleasant gargle in inflammation and ulceration of the throat. By Dr. Fahnestock an infusion of the inner bark of the root, employed as a gargle, is considered almost as a specific in the sore mouth attending inordinate mercurial salivation. (*Am. Journ. of Med. Sciences*, v. 61.) W.

* Prof. Rogers suggested that *malic acid* might be advantageously procured from this source. Prof. Procter informs us that he has obtained it by the following process. Pour boiling water on the ripe berries; macerate for twelve hours; strain, evaporate to one-fourth, and again strain; resume the evaporation and continue it till the liquid assumes the consistence of thin syrup; then set it aside to crystallize. Wash the crystals of bimalate of lime with a little water, and recrystallize from a boiling solution. Dissolve the salt in hot water, and decompose it with a solution of acetate of lead. Wash the precipitated malate of lead, suspend it in water, and pass sulphuretted hydrogen through the liquid until the whole of the lead is separated. Lastly, filter and evaporate to dryness, in a porcelain vessel. Malic acid thus obtained may be used in preparing the *malates of iron* and of *manganese*, both of which have been employed medicinally in Europe.

ROSA. See ROSA CENTIFOLIA.

Rosa canina. Willd. *Sp. Plant.* ii. 1077; Woodv. *Med. Bot.* p. 493, t. 177. The *dog rose*, *wild briar*, or *heptree*, is a native of Europe, and distinguished as a species by its glabrous ovate germs, its smooth peduncles, its prickly stem and petioles, and its ovate, smooth, rigid leaves. It is eight or ten feet in height, and bears white or pale-red flowers, having usually five obcordate fragrant petals. The plant has been introduced into this country, but is not much cultivated.

The fruit is fleshy, smooth, oval, red, and of a pleasant, sweet, acidulous taste; and contains sugar, and uncombined citric and malic acids.

The pulp, separated from the seeds and the silky bristles in which they are embedded, is employed in Europe for the preparation of a confection, intended chiefly as an agreeable vehicle for other medicines.

ROSA. *Sex. Syst.* Icosandria Polygynia.—*Nat. Ord.* Rosaceæ.

Gen. Ch. Petals five. *Calyx* urceolate, five-cleft, fleshy, contracted at the neck. *Seeds* numerous, hispid, attached to the inner side of the calyx. *Willd.*

Rosa centifolia. Willd. *Sp. Plant.* ii. 1071; Woodv. *Med. Bot.* p. 495, t. 178. This species of rose has prickly stems, which usually rise from three to six feet in height. The leaves consist of two or three pairs of leaflets, with an odd one at the end, closely attached to the common footstalk, which is rough, but without spines. The leaflets are ovate, broad, serrate, pointed, and hairy on the under surface. The flowers are large, with many petals, usually of a pale-red colour, and supported upon peduncles beset with short bristly hairs. The germ is ovate, and the segments of the calyx semi-pinnate. The varieties of *R. centifolia* are very numerous, but may be indiscriminately employed. The plant is now cultivated in gardens all over the world; but its original country is not certainly known. It has sometimes been mistaken for the damask rose, which is a distinct species.

The petals are the officinal portion. They are extremely fragrant, and have a sweetish, slightly acidulous, somewhat bitterish taste. Their odour is said to be increased by iodine. It depends on a volatile oil, which may be separated by distillation with water. (See *Oleum Rosæ.*) They should be collected when the flower is fully expanded, but has not begun to fall. Their fragrance is impaired but not lost by drying. They may be preserved fresh, for a considerable time, by compressing them with alternate layers of common salt in a well-closed vessel, or beating them with twice their weight of that substance.

The petals are slightly laxative, and are sometimes administered in the form of syrup combined with cathartic medicines; but their chief use is in the preparation of rose water. (See *Aqua Rosæ.*)

Rosa. See ROSA CENTIFOLIA.

Rosa Gallica. Willd. *Sp. Plant.* ii. 1071; Woodv. *Med. Bot.* p. 498, t. 179. This species is smaller than *R. centifolia*, but resembles it in the character of its foliage. The stem is beset with short bristly prickles. The flowers are very large, with obcordate widely spreading petals, which are of a rich crimson colour, and less numerous than in the preceding species. In the centre is a crowd of yellow anthers on thread-like filaments, and as many villose styles bearing papillary stigmas. The fruit is oval, shining, and of a firm consistence. The red rose is a native of the South of Europe, and is cultivated in gardens throughout the United States.

The petals, which are the part employed, should be gathered before the flower has blown, separated from their claws, dried in a warm sun or by the fire, and kept in a dry place. Their odour, which is less fragrant than that of *R. centifolia*, is improved by drying. They have a velvety appearance, a purplish-red colour, and a pleasantly astringent and bitterish taste. Their constituents, according to M. Cartier, are tannin, gallic acid, colouring matter, a volatile oil, a fixed oil, albumen, soluble salts of potassa, insoluble salts of lime, silica, and oxide of iron. (*Journ. de Pharm.*, vii. 531.) Their sensible properties and medical virtues are extracted by boiling water. Their infusion is of a pale reddish colour, which becomes bright red on the addition of sulphuric acid. As their colour is impaired by exposure to light and air, they should be kept in opaque well-closed bottles or canisters.

Medical Properties and Uses. Red roses are slightly astringent and tonic, and were formerly thought to possess peculiar virtues. They are at present chiefly employed in infusion, as an elegant vehicle for tonic and astringent medicines.

ROSMARINUS. *U. S., Ed., Dub.*

Rosemary.

The tops of Rosmarinus officinalis. *U. S., Ed., Dub.*

Romarin, *Fr.;* Rosmarin, *Germ.;* Rosmarino, *Ital.;* Romero, *Span.*

Rosmarinus. *Sex. Syst.* Diandria Monogynia.—*Nat. Ord.* Lamiaceæ or Labiatæ.

Gen. Ch. Corolla unequal, with the upper lip two-parted. *Filaments* long, curved, simple, with a tooth. *Willd.*

Rosmarinus officinalis. Willd. *Sp. Plant.* i. 126; Woodv. *Med. Bot.* p. 329, t. 117. Rosemary is an evergreen shrub, three or four feet high, with an erect stem, divided into many long, slender, ash-coloured branches. The leaves are numerous, sessile, opposite, more than an inch long, about one-sixth of an inch broad, linear, entire, obtuse at the summit, turned backward at the edges, of a firm consistence, smooth and green on the upper surface, whitish and somewhat downy beneath. The flowers are pale-blue or white, of considerable size, and placed in opposite groups at the axils of the leaves, towards the ends of the

branches. The seeds are four in number, of an oblong shape, and naked in the bottom of the calyx.

The plant grows spontaneously in the countries which border on the Mediterranean, and is cultivated in the gardens of Europe and this country. The flowering summits are the officinal portion. They have a strong balsamic odour, which is possessed, though in a less degree, by all parts of the plant. Their taste is bitter and camphorous. These properties are imparted partially to water, completely to alcohol, and depend on a volatile oil which may be obtained by distillation. (See *Oleum Rosmarini.*) The tops lose a portion of their sensible properties by drying, and become inodorous by age.

Medical Properties and Uses. Rosemary is gently stimulant, and has been considered emmenagogue. In the practice of this country it is scarcely used; but in Europe, especially on the continent, it enters into the composition of several syrups, tinctures, &c., to which it imparts its agreeable odour and excitant property. It is sometimes added to sternutatory powders, and is used externally in connexion with other aromatics in the form of fomentation. In some countries it is employed as a condiment; and its flowers, which are much sought after by the bees, impart their peculiar flavour to the honey of the districts in which the plant abounds.

RUBIA. *U. S. Secondary.*

Madder.

The root of Rubia tinctorum. *U. S.*

Garance, *Fr.;* Krappwurzel, *Germ.;* Robbia, *Ital.;* Rubia de tintoreros, Granza, *Span.*

RUBIA. *Sex. Syst.* Tetrandria Monogynia.—*Nat. Ord.* Rubiaceæ. *Juss.*

Gen. Ch. Corolla one-petalled, bell-shaped. *Berries* two, one-seeded. *Willd.*

Rubia tinctorum. Willd. *Sp. Plant.* i. 603; Woodv. *Med. Bot.* p. 173, t. 67.

The root of the *dyers' madder* is perennial, and consists of numerous long, succulent fibres, varying in thickness from the size of a quill to that of the little finger, and uniting at top in a common head, from which also proceed side-roots that run near the surface of the ground, and send up many annual stems. These are slender, quadrangular, jointed, procumbent, and furnished with short prickles by which they adhere to the neighbouring plants upon which they climb. The leaves are elliptical, pointed, rough, firm, about three inches long and nearly one inch broad, having rough points on their edges and midrib, and standing at the joints of the stem in whorls of four, five, or six together. The branches rise in pairs from the same joints, and bear small yellow flowers at the summit of each of their subdivisions. The fruit is a round, shining, black berry.

The plant is a native of the South of Europe, and the Levant, and is cultivated in France and Holland. It is from the latter country that commerce derives its chief supply. The root, which is the part used, is dug up in the third summer, and, having been deprived of its cuticle, is dried by artificial heat, and then reduced to a coarse powder. In this condition it is packed in barrels, and sent into the market. Madder from the Levant is in the state of the whole root, from the South of France, either whole or in powder. The plant is also cultivated in this country, in the States of Delaware and Ohio.

The root consists of a reddish-brown bark, and a ligneous portion within. The latter is yellow in the recent state, but becomes red when dried. The powder, as kept in the shops, is reddish-brown.

Madder has a weak peculiar odour, and a bitterish astringent taste; and imparts these properties, as well as a red colour, to water and alcohol. It contains,

according to M. Runge, five distinct colouring substances; a red, a purple, an orange, a yellow, and a brown. According to M. Decaisne, only yellow colouring matter is found in the recent root; and it is under the influence of atmospheric air that this changes to red. The most interesting of the colouring substances is the *alizarin* of Robiquet and Collin. This is of an orange-red colour, inodorous, insipid, crystallizable, capable of being sublimed without change, scarcely soluble in cold water, soluble in boiling water, and very readily so in alcohol, ether, the fixed oils, and liquid alkalies. The alcoholic and watery solutions are rose-coloured; the ethereal, golden-yellow; the alkaline, violet and blue when concentrated, but violet-red when sufficiently diluted. A beautiful rose-coloured lake is produced by precipitating a mixture of the solutions of alizarin and alum. Rochleder finds a close analogy between alizarin and the chrysophanic acid of rhubarb. (See *Chem. Gaz.*, A. D. 1852, p. 243.) Madder also contains sugar; and Döbereiner succeeded in obtaining alcohol from it by fermentation and distillation, without affecting its colouring properties. It is much used by the dyers.

Medical Properties and Uses. Madder was formerly thought to be emmenagogue and diuretic; and was used in amenorrhœa, dropsy, jaundice, and visceral obstructions. It is still occasionally prescribed in suppressed menstruation; but physicians generally have no confidence in its efficacy in this or any other complaint. When taken into the stomach it imparts a red colour to the milk and urine, and to the bones of animals, without sensibly affecting any other tissue. The effect is observable most quickly in the bones of young animals, and in those nearest the heart. Under the impression that it might effect some change in the osseous system, it has been prescribed in rachitis, but without any favourable result. The dose is about half a drachm, repeated three or four times a day.

W.

RUBUS TRIVIALIS. *U. S. Secondary.*

Dewberry-root.

The root of Rubus trivialis. *U. S.*

RUBUS VILLOSUS. *U. S. Secondary.*

Blackberry-root.

The root of Rubus villosus. *U. S.*

Rubus. *Sex. Syst.* Icosandria Polygynia.—*Nat. Ord.* Rosaceæ.

Gen. Ch. Calyx five-cleft. *Petals* five. *Berry* compound, with one-seeded acini. *Willd.*

Of this extensive genus not less than twenty species are indigenous in the United States, where they are called by the various names of *raspberry*, *blackberry*, *dewberry*, *cloudberry*, &c. Most of them are shrubby or suffruticose briers, with astringent roots and edible berries; some have annual stems without prickles. The only officinal species are the *R. trivialis* and *R. villosus*, which, so far as relates to their medical properties, are so closely alike as not to require a separate description.

1. *Rubus trivialis.* Michaux, *Flor. Americ.* i. 296. The *dewberry*, sometimes also called *low blackberry*, or *creeping blackberry*, has a slender, prickly stem, which runs along the ground, and occasionally puts forth roots. The leaves are petiolate, and composed of three or five leaflets, which are oblong-oval, acute, unequally serrate, and somewhat pubescent. The stipules are awl-shaped. The flowers are large, white, and nearly solitary, with elongated pedicels, and peduncles

which, like the leafstalks, are armed with recurved, hispid prickles. The petals are generally obovate, and three times longer than the calyx. In one variety they are orbicular. The plant grows abundantly in old fields and neglected grounds in the Middle and Southern States. Its fruit is large, black, of a very pleasant flavour, and ripens somewhat earlier than that of *R. villosus.* According to Torrey and Gray, the dewberry of the Northern States is the *Rubus Canadensis* of Linn., or *R. trivialis* of Pursh. (*Flor. of N. Am.* i. 455.)

2. *R. villosus.* Willd. *Sp. Plant.* ii. 1085; Bigelow, *Am. Med. Bot.* ii. 160; Barton, *Med. Bot.* ii. 151. The stem of the blackberry is somewhat shrubby, from three to seven feet high, branching, more or less furrowed and angular, and armed with strong prickles. The smaller branches and young shoots are herbaceous. The leaves are ternate or quinate; the leaflets ovate, acuminate, unequally and sharply serrate, and pubescent on both sides; the footstalk and midrib usually armed with short recurved prickles. The flowers are large, white, and in erect racemes, with a hairy, prickly stalk. The calyx is short, with acuminate segments. The fruit is first green, then red, and, when perfectly ripe, of a shining black colour and very pleasant taste. It is a compound berry, consisting of numerous pulpy one-seeded globules or acini attached to the receptacle. This species of Rubus is, perhaps, the most abundant of those indigenous in the United States, growing in neglected fields, along fences, on the borders of woods, in forest glades, and wherever tillage or too much shade and moisture does not interfere with it. Its flowers appear from May to July, and its fruit is ripe in August.

The berries of both these species of Rubus are much used as food; and a jelly made from them is in great esteem as an article of diet, and even as a remedy in dysenteric affections. The roots only are officinal.

The blackberry root is branching, cylindrical, of various dimensions, from nearly an inch in thickness down to the size of a straw, ligneous, and covered with a thin bark, which is externally of a light-brownish or reddish-brown colour, and in the dried root is wrinkled longitudinally. The dewberry root is usually smaller, without the longitudinal wrinkles, but with transverse fissures through the epidermis, and of a dark-ash colour, without any reddish tinge. Both are inodorous. The bark in both has a bitterish strongly astringent taste, and the ligneous portion is nearly insipid, and comparatively inert. The smaller roots, therefore, should be selected for use; or, if the thicker pieces are employed, the cortical part should be separated, and the wood rejected. Their virtues are extracted by boiling water, and by diluted alcohol, and depend chiefly, if not exclusively, upon tannin, which experiment has proved to be an abundant constituent.

Medical Properties and Uses. Dewberry and blackberry roots are tonic and strongly astringent. They have long been a favourite domestic remedy in bowel affections; and from popular favour have passed into regular medical use. Given in the form of decoction, they are usually acceptable to the stomach, without being offensive to the taste; and may be employed with great advantage in cases of diarrhœa from relaxation of the bowels, whether in children or adults. We can add our own decided testimony to that of others who have spoken favourably of their use in this complaint; and there is no doubt that they are applicable to all other cases in which the vegetable astringents are found serviceable. The decoction may be prepared by boiling an ounce of the smaller roots, or of the bark of the larger, in a pint and a half of water down to a pint; of which from one to two fluidounces may be given to an adult three or four times, or more frequently, during the twenty-four hours. The dose of the powdered root is twenty or thirty grains. W.

RUMEX BRITANNICA. *U.S. Secondary.*

Water Dock.

The root of Rumex Britannica. *U. S.*

RUMEX OBTUSIFOLIUS. *U.S. Secondary.*

Blunt-leaved Dock.

The root of Rumex obtusifolius. *U. S.*

Rumex. *Sex. Syst.* Hexandria Trigynia.—*Nat. Ord.* Polygonaceæ.

Gen. Ch. Calyx three-leaved. *Petals* three, converging. *Seed* one, three-sided. *Willd. Calyx* six-parted, persistent, the three interior divisions petaloid, connivent. *Seed* one, three-sided, superior, naked. *Stigmata* multifid. *Nuttall.*

Several species of Rumex have acid leaves, and are distinguished by the common name of *sorrel* from the others, which are called *dock*. Of the former, *Rumex Acetosa* or *common English sorrel*, has but recently been dismissed from the London and Dublin Pharmacopœias. *R. Acetosella* is the common sorrel of our fields, though supposed to have been originally introduced from Europe. The leaves of both these plants are agreeably sour to the taste, and owe their acidity to binoxalate of potassa with a little tartaric acid. They quite lose this taste in drying. They are refrigerant and diuretic, and may be used advantageously as an article of diet in scorbutic complaints. For this purpose they are prepared in the form of salad. The juice of the leaves forms with water an agreeable acidulous drink, sometimes used in fevers. Taken very largely, the leaves are said to have produced poisonous effects. (See *Wood's Quarterly Retrospect*, i. 109.) *R. scutatus* also ranks among the sorrels.

Of the proper docks, though two only are recognised by the Pharmacopœia, several others have been used. The roots of *R. Patientia* and *R. Alpinus*, European plants, and of *R. aquaticus*, *R. crispus*, *R. acutus*, and *R. sanguineus*, belonging both to Europe and the United States, may be employed indiscriminately with those of the officinal species. *R. Hydrolapathum* (*Hudson*), which is the *R. aquaticus* of the late Dublin Pharmacopœia, is thought to be the *Herba Britannica* of the ancients, celebrated for the cure of scurvy and diseases of the skin. The docks are herbaceous plants with perennial roots. Their flowers are in terminal or axillary panicles. Some of the species are dicœcious; but those here described have perfect flowers.

1. *R. Britannica.* Willd. *Sp. Plant.* ii. 250. This species is distinguished in the vernacular language by the name of *yellow-rooted water dock*. The root is large, dark on the outside, and yellow within. The stem is two or three feet high, and bears broad-lanceolate, smooth, flat leaves, with the sheathing stipules slightly torn. The spikes of the panicle are leafless; the valves entire and all graniferous. The plant is indigenous, inhabiting low, wet places, and flowering in June and July.

2. *R. obtusifolius.* Willd. *Sp. Plant.* ii. 254; Loudon's *Encyc. of Plants*, p. 293. The root of the *blunt-leaved dock* is externally brown, internally yellow; the stem two or three feet high and somewhat rough; the radical leaves ovate-cordate, obtuse, and very large; the valves dentate, and one of them conspicuously graniferous. It is a common weed in our rich grounds and pastures, but is supposed to have been introduced from Europe. Its flowers appear in June and July.

Dock root, from whatever species derived, has an astringent, bitter taste, with

little or no smell. It readily yields its virtues to water by decoction. According to Riegel, the root of *R. obtusifolius* contains a peculiar principle called *rumicin*, resin, extractive matter resembling tannin, starch, mucilage, albumen, lignin, sulphur, and various salts, among which are the phosphate of lime, and different acetates and malates. (*Journ. de Pharm.*, 3e *sér.*, i. 410.) Rumicin is probably, like rhabarbaric acid, an impure form of chrysophanic acid. (See *Rheum.*) The leaves of most of the species are edible, and are occasionally used as spinage. They are somewhat laxative, and form an excellent diet in scorbutic cases. The roots are used to dye a yellow colour.

Medical Properties and Uses. The medical properties of dock root are those of an astringent and mild tonic. It is also supposed to possess an alterative property, which renders it useful in scorbutic disorders, and cutaneous eruptions, particularly the itch, in the cure of which it enjoyed at one time considerable reputation. It is said to have proved useful in scrofula and syphilis. Dr. Thomson found a decoction of the root of *R. Patientia* very efficacious in obstinate ichthyosis. *R. aquaticus* and *R. Britannica* are the most astringent. The roots of some species unite a laxative with the tonic and astringent property, resembling rhubarb somewhat in their operation. Such are those of *R. crispus* and *R. obtusifolius;* and *R. Alpinus* has in some parts of Europe the name of *mountain rhubarb.* This resemblance of properties is not singular, as the two genera belong to the same natural family. Dock root is given in powder or decoction. Two ounces of the fresh root bruised, or one ounce of the dried, may be boiled in a pint of water, of which two fluidounces may be given at a dose, and repeated as the stomach will bear it. The root has often been applied externally in the shape of ointment, cataplasm, and decoction, to the cutaneous eruptions and ulcerations for which it has been used internally. The powdered root is recommended as a dentifrice, especially when the gums are spongy. W.

RUTA. *U. S. Secondary, Lond., Ed.*

Rue.

The leaves of Ruta graveolens, *U.S., Lond.* Leaves and unripe fruit. *Ed.* Rue odorante, *Fr.;* Garten-Raute, *Germ.;* Ruta, *Ital.;* Ruda, *Span.*

RUTA. *Sex. Syst.* Decandria Monogynia.—*Nat. Ord.* Rutaceæ.

Gen. Ch. Calyx five-parted. *Petals* concave. *Receptacle* surrounded by ten melliferous points. *Capsule* lobed. *Willd.*

Ruta graveolens. Willd. *Sp. Plant.* ii. 542; Woodv. *Med. Bot.* p. 487, t. 174. Common rue is a perennial plant, usually two or three feet high, with several shrubby branching stems, which, near the base, are woody and covered with a rough bark, but in their ultimate ramifications are smooth, green, and herbaceous. The leaves are doubly pinnate, glaucous, with obovate, sessile, obscurely crenate, somewhat thick and fleshy leaflets. The flowers are yellow, and disposed in a terminal branched corymb upon subdividing peduncles. The calyx is persistent, with four or five acute segments; the corolla consists of four or five concave petals, somewhat sinuate at the margin. The stamens are usually ten, but sometimes only eight in number. The plant is a native of the South of Europe, but cultivated in our gardens. It flowers from June to September. The whole herb is active; but the leaves are usually employed.

These have a strong disagreeable odour, especially when rubbed. Their taste is bitter, hot, and acrid. When recent, and in full vigour, they have so much acrimony as to inflame and even blister the skin, if much handled; but the acrimony is diminished by drying. Their virtues depend chiefly on a volatile oil, which is very abundant, and is contained in glandular vesicles, apparent over

the whole surface of the plant. (See *Oleum Rutæ.*) They contain, also, according to Mähl, chlorophylle, albumen, an azotized substance, extractive, gum, starch or inulin, malic acid, and lignin; and, according to Bornträger, a peculiar acid which he calls *rutinic acid.* (See *Chem. Gazette, Sept.* 1845, p. 385.) Both alcohol and water extract their active properties.

Medical Properties and Uses. Rue is stimulant and antispasmodic, and, like most other substances which excite the circulation, occasionally increases the secretions, especially when deficient from debility. It appears to have a tendency to act upon the uterus; in moderate doses proving emmenagogue, and in larger doses producing a degree of irritation in that organ which sometimes determines abortion. Taken very largely it acts as an acrid narcotic poison. Three cases are recorded by Dr. Hélie in which it was taken by pregnant women, with the effect of producing dangerous gastro-intestinal inflammation and cerebral derangement, which continued for several days, but from which the patients ultimately recovered. In each instance miscarriage resulted. Great depression and slowness of the pulse attended the narcotic action of the poison. In one of the cases, three fresh roots of the size of the finger were used in the form of decoction. (*Ann. d'Hyg. Pub. et de Méd. Lég.*, xx. 180.) A case is recorded by Dr. G. F. Cooper in the *Nashville Journ. of Med. and Surg.*, in which a man, convalescent from dysentery, having added some brandy to a handful of the bruised herb, expressed it, and took the whole of the liquor with fatal effects. The prominent symptoms were vomiting, violent tormina, tenesmus, with bloody stools, abdominal distension with tenderness, and severe strangury. (*Med. Exam.*, N. S., ix. 720.) Rue is sometimes used in hysterical affections, worms, flatulent colic, and amenorrhœa, particularly in the last complaint. The ancients employed it as a condiment, and believed it to possess, besides other valuable properties, that of resisting the action of poisons. Its excitant and irritating properties require that it should be used with caution. The dose of the powder is from fifteen to thirty grains two or three times a day. The medicine is also given in infusion and extract.

SABADILLA. *U.S., Ed.*

Cevadilla.

The seeds of Veratrum Sabadilla. *U.S.* Fruit of Veratrum Sabadilla, Helonias officinalis, and probably of other Melanthaceæ. *Ed.*

Cévadille, *Fr.;* Sabadillsame, *Germ.;* Cebadilla, *Span.*

There has been much uncertainty in relation to the botanical origin of cevadilla. At one time, it was generally believed to be derived from *Veratrum Sabadilla,* which is recognised in the U. S. Pharmacopœia. But Schiede, during his travels in Mexico, ascertained that it was, in part at least, collected from a different plant, of the same natural order of Melanthaceæ, growing upon the eastern declivity of the Mexican Andes. This was considered by Schlechtendahl as another species of Veratrum, by Don as a Helonias, and by Lindley as belonging to a new genus which he named Asagræa. Hence it has been variously denominated *Veratrum officinale, Helonias officinalis,* and *Asagræa officinalis.* The Edinburgh College recognises this plant, under Don's title of Helonias officinalis, as one of the sources of cevadilla, but refers the drug also to Veratrum Sabadilla, and admits other plants of the same order as probable sources of it. More exact information, however, is wanted before we can determine its precise origin. It has been adopted in the Pharmacopœias solely on account

of its employment in the preparation of veratria. It is brought from Vera Cruz.*

Cevadilla seeds usually occur in commerce mixed with the fruit of the plant. This consists of three coalescing capsules or follicles, which open above, and present the appearance of a single capsule with three cells. It is three or four lines long and a line and a half in thickness, obtuse at the base, light-brown or yellowish, smooth, and in each capsule contains one or two seeds. A resemblance existing or supposed between this fruit and that of barley, is said to have given rise to the Spanish name cevadilla, which is a diminutive of barley. The seeds are elongated, pointed at each end, flat on one side and convex on the other, somewhat curved, two or three lines long, wrinkled, slightly winged, black or dark-brown on the outside, whitish within, hard, inodorous, and of an exceedingly acrid, burning, and durable taste. Cevadilla was found by Pelletier and Caventou to contain a peculiar organic alkali which they named *veratria*, combined with gallic acid; fatty matter, consisting of olein, stearin, and a peculiar volatile fatty acid denominated *cevadic* or *sabadillic acid;* wax; yellow colouring matter; gum; lignin; and salts of potassa and of lime, with a little silica. From 100 parts of the seeds, separated from their capsules, Meissner obtained 0·58 of veratria. M. Couërbe discovered another alkaloid in the seeds which he denominated *sabadillin*. Besides the principles above mentioned, a peculiar acid was discovered by Merck, called *veratric acid*, which is in colourless crystals, fusible and volatilizable without decomposition, but slightly soluble in cold water, more soluble in hot water, soluble in alcohol, insoluble in ether, having the properties of reddening litmus paper, and forming soluble salts with the alkalies. For an account of the mode of preparing veratria, its properties, and remedial applications, and for a more particular notice of sabadillin (*sabadillia*), see the article *Veratria* in the second part of this work.

Medical Properties and Uses. Cevadilla is an acrid drastic emeto-cathartic, operating occasionally with great violence, and in over-doses capable of producing fatal effects. It was made known as a medicine in Europe so early as the year 1572; but has never been much employed. It has been chiefly used as an anthelmintic, especially in cases of tænia, in which it has been given in doses varying

* Until more definite information is obtained on the subject, we give in a note a brief description of the two plants above referred to.

Veratrum Sabadilla. Retzius, *Obs.* i. 31; Carson, *Illust. of Med. Bot.* ii. 50, pl. 94. See *Veratrum Album.* The leaves of this plant are numerous, ovate-oblong, obtuse, with from eight to fourteen ribs, glaucous beneath, and all radical. The flower-stem is erect, simple, and round, rises three or four feet in height, and bears a spreading, simple, or but slightly branched panicle of somewhat nodding flowers, supported upon very short pedicels. The flowers, which are of a blackish-purple colour, approximate in twos and threes, the fertile turning at length to one side, and the sterile falling off. The segments of the corolla are ovate-lanceolate, and without veins. The capsules occupy only one side of the stem. This plant grows in Mexico and the West Indies, and was cultivated by Descourtilz at San Domingo, from seeds obtained in Mexico.

Asagræa officinalis. Lindley, *Botan. Reg.*, June, 1839. — *Veratrum officinale.* Schlechtendahl, *Linnæa*, vi. 45. — *Helonias officinalis.* Don. *Ed. New Phil. Journ.*, October, 1832, p. 234. The following is the generic character given by Lindley. "*Flowers* polygamous, racemose, naked. *Perianth* six-partite; segments linear, veinless, almost equal, with a nectariferous excavation at the base, equal to the stamens. *Stamens* alternately shorter; anthers cordate as if unilocular, after dehiscence shield-shaped. *Ovaries* three, quite simple, attenuated into an obscure stigma. *Follicles* three, acuminate, papery; seeds scimitar-shaped, corrugated, winged. Bulbous herbs, with grass-like leaves, and small, pale, and densely racemed flowers." The *A. officinalis*, which is the only known species, has linear, acuminate, subcarinate leaves, roughish at the margin, and four feet in length by three lines in breadth, and a round flower stem, about six feet high, terminating in a very dense, straight, spike-like raceme, eighteen inches long. The flowers are white, with yellow anthers.

from five to thirty grains. It has also been given in different nervous affections. It is the principal ingredient of the *pulvis Capucinorum*, sometimes used in Europe for the destruction of vermin in the hair. It is considered by the natives of Mexico useful in hydrophobia, and was employed by M. Fouilhoux, of Lyons, in a supposed case of that disease, in the dose of about nine grains, with asserted success. Externally applied, it is highly irritating, and is even said to be corrosive. Its chief employment at present is for the preparation of veratria.

SABBATIA. *U.S.*

American Centaury.

The herb of Sabbatia angularis. *U. S.*

Sabbatia. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Gentianaceæ.

Gen. Ch. Calyx five to twelve-parted. *Corolla* rotate, five to twelve-parted. *Stigmas* two, spiral. *Anthers* at length revolute. *Capsule* one-celled, two-valved, many-seeded. *Nuttall.*

Sabbatia angularis. Pursh, *Flor. Am. Sept.* 137; Bigelow, *Am. Med. Bot.* iii. 147; Barton, *Med. Bot.* i. 255.—*Chironia angularis.* Linn. The American centaury is an annual or biennial herbaceous plant, with a fibrous root, and an erect, smooth, four-sided stem, winged at the angles, simple below, sending off opposite axillary branches above, and rising one or two feet in height. The leaves, which vary considerably in length and width, are ovate, entire, acute, nerved, smooth, opposite, and sessile, embracing half the circumference of the stem at their base. The flowers are numerous, growing on the ends of the branches, and forming altogether a large terminal corymb. The calyx is divided into five lanceolate segments, considerably shorter than the corolla. This is deeply five-parted, with obovate segments of a beautiful delicate rose-colour, which is paler and almost white in the middle of their under surface. The anthers are yellow, and, after shedding their pollen, become revolute. The style, which is bent downward, and is longer than the stamens, terminates in two linear stigmas, which become spirally twisted together.

The plant is widely diffused through the Middle and Southern States, growing in low meadow grounds, and in wet seasons upon uplands, in woods and neglected fields. It flowers in July and August. In its general aspect as well as medical properties, it bears a close resemblance to *Erythræa Centaurium*, or European centaury, for which it was mistaken by the earlier settlers. The whole herb is employed, and should be collected when in flower.

All parts of it have a strongly bitter taste, without any admixture of astringency, or other peculiar flavour. Both alcohol and water extract its bitterness, together with its medical virtues.

Medical Properties and Uses. American centaury has the tonic properties of the simple bitters, and is very analogous in its action to the other plants belonging to the same natural family. It has long been popularly employed as a prophylactic and remedy in our autumnal intermittent and remittent fevers; and was formerly much esteemed by some physicians in the latter of these complaints. The condition to which it was considered applicable, was that existing between the paroxysms, when the remission was such as to call for the use of tonics, but was not deemed sufficient to justify a resort to the preparations of Peruvian bark. It is occasionally useful, during the progress of a slow convalescence, by promoting appetite and invigorating digestion; and may be employed for the same purpose in dyspepsia and diseases of debility.

The most convenient form for administration is that of infusion. A pint of

boiling water poured on an ounce of the herb and allowed to cool, may be given in the dose of two fluidounces, repeated every hour or two during the remission of fevers, and less frequently in chronic affections. The dose of the powder is from thirty grains to a drachm. The decoction, extract, and tincture are also efficient preparations. W.

SABINA. *U. S., Lond., Ed., Dub.*

Savine.

The tops of Juniperus Sabina. *U. S., Ed., Dub.* The recent and dried tops. *Lond.*

Sabine, *Fr.;* Sevenbaum, *Germ.;* Sabina, *Ital., Span.*

JUNIPERUS. See JUNIPERUS.

Juniperus Sabina. Willd. *Sp. Plant.* iv. 852; Woodv. *Med. Bot.* p. 10, t. 5. This is an evergreen shrub, from three to fifteen feet in height, with numerous erect, pliant branches, very much subdivided. The bark of the young branches is light-green, that of the trunk rough and reddish-brown. The leaves, which completely invest the younger branches, are numerous, small, erect, firm, smooth, pointed, dark-green, glandular in the middle, opposite, and imbricated in four rows. The flowers are male and female on different trees. The fruit is a blackish-purple berry, of an ovoid shape, marked with tubercles and the remains of the calyx and petals, and containing three seeds.

The savine is a native of the South of Europe and the Levant, and is said to grow wild in the neighbourhood of our north-western lakes. The ends of the branches, and the leaves by which they are invested, are collected for medical use in the spring. When dried they fade very much in colour.

There is reason to believe that the tops of *Juniperus Virginiana*, or common red cedar, are sometimes substituted in the shops for the savine, to which they bear so close a resemblance as to be with difficulty distinguished. The two species, however, differ in their taste and smell. In *J. Virginiana*, moreover, the leaves are sometimes ternate.

The tops and leaves of the savine plant have a strong, heavy, disagreeable odour, and a bitter, acrid taste. These properties, which are less striking in the dried than in the recent leaves, are owing to a volatile oil, which is obtained by distillation with water. (See *Oleum Sabinæ.*) The leaves impart their virtues to alcohol and water. From an imperfect analysis by Mr. C. H. Needles, they appear to contain volatile oil, gum, tannic or gallic acid, resin, chlorophylle, fixed oil, bitter extractive, lime, and salts of potassa. (*Am. Journ. of Pharm.*, xiii. 15.)

Medical Properties and Uses. Savine is highly stimulant, increasing most of the secretions, especially those of the skin and uterus, to the latter of which organs it is supposed to have a peculiar direction. It has been much used in amenorrhœa, and occasionally as a remedy for worms. Dr. Chapman strongly recommended it in chronic rheumatism; and it is employed in Germany, both internally and externally, in chronic gout. In overdoses it is capable of producing dangerous gastro-intestinal inflammation, and should therefore be used with caution. In no case should it be employed when much general or local excitement exists. In pregnancy it should always be given with great caution; though it has recently been recommended as an effective remedy in certain forms of menorrhagia, and is asserted to prove occasionally useful in preventing threatened abortion. (See *Am. Journ. of Med. Sci.*, N. S., viii. 475.) It is most conveniently administered in the form of powder, of which the dose is from five to fifteen grains, repeated three or four times a day.

As an external irritant it is useful, in the form of cerate, for maintaining a

discharge from blistered surfaces; but, as the preparation sold in this country under the name of savine ointment is often feeble, either from the age of the drug, or the substitution of red cedar, it has in some measure fallen into disrepute. (See *Ceratum Sabinæ.*) In powder or infusion, savine is used in Europe as an application to warts, indolent, carious, and gangrenous ulcers, psora, and tinea capitis; and the expressed juice of the fresh leaves, diluted with water, is sometimes applied to similar purposes.

The saccharine principles distinguished by the chemist are cane sugar, or sugar properly so called, derived from the sugar cane, the beet, and the sugar maple; glucose or grape sugar, with which the crystallizable sugar of honey, starch sugar, and diabetic sugar are identical; uncrystallizable sugar, or *fruit sugar*, called by Soubeiran *chulariose* (from χυλαριον, syrup); *sorbin*, or the sugar of the berries of the mountain ash (*Sorbus aucuparia*); lactin, or sugar of milk; sugar of ergot, improperly called mushroom sugar; mannite; and glycerin. *Glucose* or *grape sugar* is less sweet than cane sugar. It is also less soluble in water, and much more soluble in alcohol. It has the sp. gr. of 1·386. Obtained from a concentrated aqueous solution, it forms crystalline grains. Strong mineral acids hardly act on grape sugar, but destroy cane sugar with facility. On the other hand, grape sugar is destroyed by alkalies, with which cane sugar forms definite compounds. Dissolved in water and subjected to prolonged ebullition, grape sugar undergoes very little alteration. Its solution rotates the plane of polarization of polarized light to the right, and is capable of undergoing the vinous fermentation directly, without passing through any intermediate state. *Uncrystallizable sugar* exists in honey and the juice of fruits, and is generated from cane sugar by solution in

water or weak acids, and long boiling. Hence it is present in molasses. The view of Liebig that uncrystallizable sugar, whether derived from fruits, or generated by weak acids, is really a combination of ordinary sugar with an acid, has been disproved by Soubeiran, who obtained it exempt from acid, and, therefore, considers it a distinct kind of sugar. An aqueous solution of this sugar turns the plane of polarization to the left, and, like grape sugar, is susceptible of the vinous fermentation without an intermediate change. Uncrystallizable sugar is transformed into grape sugar, when it is made to assume a crystalline structure, but not by mere solidification. (*Soubeiran.*) A solution of *cane sugar*, like that of grape sugar, has a rotating power to the right. When it ferments, it is not, as is generally supposed, first converted into grape sugar. It is found both by Mitscherlich and Soubeiran to be first changed into uncrystallizable sugar; and, as the change proceeds, the rotating power to the right of the cane sugar gradually lessens and disappears, and is replaced by the rotating power to the left of the uncrystallizable sugar formed. *Sorbin* was discovered by M. Pelouze. It is in perfectly transparent crystals, having the same taste as cane sugar, but is not susceptible of fermentation. *Lactin* or *sugar of milk* is now officinal with the Dublin College, *Pharm.* of 1850. (See *Saccharum Lactis.*) For a description of *mannite* and *glycerin*, see the articles *Manna* and *Glycerina.*

Cane sugar is manufactured extensively on the continent of Europe from the beet, and in considerable quantities, in Canada and the north-western parts of the United States, from the sap of the sugar maple (*Acer Saccharinum*). In relation to maple sugar, see a paper by Dr. George D. Gibb, in the *Brit. Am. Journ. of Med. Sci.* for July, 1851. Cane sugar may also be obtained from cornstalks. (*H. L. Ellsworth.*) In India, it is made from the sap of different species of palm. In 1844, more than 6000 tons of crude *palm sugar*, called *jaggary*, were manufactured. It is more easily refined, and at less cost than the sugar from the cane. (*Stevens.*) But the supply of sugar from these sources is insignificant when compared with that obtained from the sugar cane itself, which is extensively cultivated in the East and West Indies, Brazil, and some of our Southern States, particularly Louisiana. This plant is the *Saccharum officinarum* of botanists, and is the source of the officinal sugars of the Pharmacopœias.

Saccharum. *Sex. Syst.* Triandria Digynia.—*Nat. Ord.* Graminaceæ.

Gen. Ch. Calyx two-valved, involucred, with long down. *Corolla* two-valved. *Willd.*

Saccharum officinarum. Willd. *Sp. Plant.* i. 321; *Phil. Trans.* lxix. 207. The *sugar cane* is an herbaceous plant, possessing a jointed, succulent root, from which arise several shining, jointed, solid stems, from an inch to two inches in diameter, and from six to twelve feet high, and containing a white and juicy pith. The colour of the stem is yellow, greenish-yellow, purple, or striped. The joints are about three inches apart, and give origin to the leaves, which embrace the stem at their base, are three or four feet long and about an inch wide, flat, acuminate, longitudinally striated, furnished with a white midrib, glabrous, finely dentate, and of a green colour inclining to yellow. The flowers are pinkish, surrounded by a long silky down, and disposed in a large, terminal, nearly pyramidal panicle, composed of subdivided spikes, and two or three feet in length. The plant has a general resemblance to the Indian corn. Four varieties are mentioned; 1. the *common*, with a yellow stem; 2. the *purple*, with a purple stem and richer juice; 3. the *gigantic*, with a very large light-coloured stem; and 4. the *Otaheitan*, which was introduced into the West Indies from the island of Tahiti (Otaheite) by Bougainville and Bligh, and is distinguished by its greater height, the longer intervals between its joints, and by the greater length of the hairs which surround the flowers.

The sugar cane is cultivated by cuttings, which are planted in rows, and which, by giving rise to successive shoots, furnish five or six crops before the plants require to be renewed. At the end of a year the plant generally flowers, and in four or five months afterwards the canes are completely ripe, at which time they have a yellowish colour, and contain a sweet viscid juice. The quantity of sugar which they yield is variable. According to Avequin, of New Orleans, the proportion of cane sugar in the recent stalk is about 10 per cent., of uncrystallizable sugar from $3\frac{1}{2}$ to 4 per cent. Cane-juice is usually stated to contain from seventeen to twenty-three per cent. of crystallizable sugar, though scarcely seven per cent. is extracted in practice.

Preparation and Purification. The canes, when ripe, are cut down close to the earth, topped, and stripped of their leaves, and then crushed between vertical iron rollers in a kind of mill. The juice, constituting ninety per cent. of the cane, though fifty per cent. is scarcely obtained in practice, is of a pale-greenish colour, sweet taste, and balsamic odour, and has a sp. gr. varying from 1·033 to 1·106. As it runs out it is received in suitable vessels, and, being quickly removed, is immediately mixed with lime, in the form of milk of lime, in the proportion of about one part of the earth to eight hundred of the juice, and heated in a boiler to 140°. The exact proportion of the lime cannot be determined, as the juice varies in quality in different seasons; but the manufacturer should aim at making the liquor neutral, or very slightly alkaline. The gluten and albumen rise to the top, and form a thick scum, from underneath which the liquid is drawn off by a cock into a copper boiler, where it is concentrated by ebullition, the scum being carefully skimmed off as it forms. Filtering the juice through cloth filters before heating it is advantageous. When sufficiently concentrated, the juice is transferred to shallow vessels called coolers, from which, before it cools, it is drawn off into wooden vessels, with perforated bottoms, the holes in which are temporarily plugged. At the end of twenty-four hours, the liquid is strongly agitated with wooden stirrers, in order to accelerate the granulation of the sugar, which is completed in six hours. The stoppers are now removed, and the syrup is allowed to drain off from the sugar, which in this state is granular, of a yellowish colour, and moist. It is next dried in the sun, and, being introduced into hogsheads, forms the *brown sugar* of commerce. The syrup, by a new evaporation, furnishes an additional portion of sugar; and the liquid which finally remains, incapable of yielding more sugar with advantage, is called *molasses*. Eight pounds of the juice yield, on an average, one pound of brown sugar. In the process of extraction, it is important that the juice should be concentrated by a moderate heat, which prevents the cane sugar from being converted into uncrystallizable sugar, and, therefore, lessens the amount of the molasses. Sometimes the brown sugar undergoes an additional preparation, consisting in boiling it with lime-water, and, after sufficient concentration, allowing the syrup to crystallize in large inverted conical vessels, pierced at the apex and plugged. The surface of the crystalline mass being covered with a thin mixture of clay and water, the plug is removed, and the water from the clay, percolating the mass, removes the coloured syrup, which flows out at the hole. The sugar, as thus prepared, approaches to the white state, and constitutes the clayed sugar of commerce, usually called in this country *Havana sugar*.

There is no doubt that a large proportion of the sugar is lost in the ordinary process of manufacture; and several plans have been proposed to prevent this loss. In December 1847, Dr. John Scoffern, of England, took out a patent for the use of subacetate of lead as a purifying agent, added to the cane-juice in the proportion of one-sixth of one per cent.* As applied to cane-juice, it sepa-

* It is alleged that Mr. Sievier took out a patent for the same process in July, 1847, five months before the date of Dr. Scoffern's patent, and that the former employed the

rates the impurities completely, thus avoiding the labour of skimming, and furnishes the whole of the sugar, instead of about one-third, as by the ordinary process. When used in refining operations, it enables the refiner to work up residues, which would not furnish sufficient sugar to repay the cost of the old process. The lead is finally removed from the sugar solutions in the form of sulphite of lead, by the action of sulphurous acid gas, forced through them by mechanical means. In this way Dr. Scoffern alleges that the whole of the lead may be separated; but even if it is not, he believes that a minute proportion of sulphite of lead in the sugar would not prove injurious. In this opinion he is supported by several eminent chemists and physicians; but the position is controverted by others equally eminent, and, we think, on just grounds; as we should feel doubt of the wholesomeness of an aliment, so extensively used as sugar, containing a proportion of lead, however minute. Such is the view taken in France, where the process of Dr. Scoffern has been prohibited. Another patented process for the defecation of cane-juice, and of the syrups of sugar refineries, is that of R. & J. Oxland, in which acetate of alumina is used. The details of the process are given in the *Chem. Gazette* for Nov. 16, 1849, to which the reader is referred. M. Melsens, Professor of Chemistry at Brussels, has proposed a third process, which consists in the use of bisulphite of lime. This salt is said to act as an antiseptic, preventing the operation of any ferment; as an absorber of oxygen, opposing the action of that gas on the juice; as a clarifier, rendering insoluble at 212° all coagulable matters; as a bleacher of pre-existing colouring matters, and a preventive of the formation of new ones; and, lastly, as a substance furnishing a base to neutralize hurtful acids, which unite with the lime, displacing the weaker sulphurous acid. M. Melsens acknowledges that he has made his experiments, on the sugar-cane, on a small scale only, and, therefore, leaves the application of the principles of his method to the intelligence of the manufacturers themselves. (*Chem. Gaz.*, Jan. 15, 1850.)

The refining of brown sugar forms a distinct branch of business, and the methods pursued have undergone many improvements. By the original process, the sugar was boiled with lime-water, and clarified by heating it with bullocks' blood. The clarified syrup was then strained through cloth filters, whereby it was rendered limpid. It was next transferred to a boiler, where it was subjected to ebullition, until it was brought to a proper concentration; when it was allowed to cool in conical moulds, and to drain for the separation of the molasses. This last boiling required to be continued so long, that the action of the fire and air frequently decomposed the sugar to such an extent as to cause a loss of twenty-five per cent. in molasses. This disadvantage led to the abandonment of prolonged boiling; and now the sugar refiners boil the syrup in shallow boilers, which are suspended in such a way as to admit of their being emptied with the greatest quickness, without putting out the fire.

The process of refining was still further improved by Messrs. Philip Taylor and Howard. The former introduced the improvement of heating the syrup with great rapidity by means of steam, made to pass through a series of tubes traversing the boiler; and the latter devised the plan of causing the syrup to boil under a diminished pressure, created by a suction pump, set in motion by a steam engine, while it was heated by steam circulating round the boiler. In this way, the syrup was made to boil at a lower temperature, and with a diminished contact of the air; and the loss of the cane sugar, by its conversion into uncrystallizable sugar, was in a great measure avoided.

latter as a professional chemist to perfect the details of the process. (*Pharm. Journ. and Trans.*, ix. 220, Nov. 1849.) Subsequently Mr. Sievier compromised with Dr. Scoffern in regard to their conflicting claims, leaving to the latter undisputed possession of the patent.

After the syrup is sufficiently concentrated by any one of these methods, it is transferred to coolers, where it is agitated to cause it to granulate. In this state it is poured into unglazed earthenware moulds of a conical shape, with a hole in the apex, which is stopped with a paper plug. The moulds are placed, with the apex downwards, above stone-ware pots, intended to receive the uncrystallizable syrup. When the mass has completely concreted, the moulds are unstopped, to allow the coloured syrup to drain off. To remove the remains of this syrup, the operation called *claying* is performed. This consists in removing from the base of the loaf a layer of the sugar, about an inch thick, and replacing it with pure sugar in powder, which is covered with a mixture of pipe clay and water, of about the consistence of cream. The water gradually leaves the clay, dissolves the pure sugar, and percolates the mass as a pure syrup, removing in its progress the coloured syrup. Sometimes the purification is performed without the use of clay, by allowing a saturated solution of pure sugar to percolate the loaf. When all the coloured syrup is removed, the loaf is taken out of the mould and placed in stoves to dry. It now constitutes *white* or *purified sugar*. The syrup which drains from the loaves contains a considerable quantity of cane sugar, and is used in subsequent operations. The syrups of lowest quality are employed in forming inferior white sugar, from which a syrup finally drains, containing so little cane sugar as not to repay the expense of extracting it. This constitutes *sugar house molasses*. Good brown sugar, in the process of refining, yields about 70 per cent. of white sugar.

Of the several forms of sugar above mentioned, three only, *white* and *brown sugar*, and *molasses*, are officinal in the British and United States Pharmacopœias, and these are designated by the Latin names placed at the head of this article. The United States Pharmacopœia recognises white sugar only, giving it the name of *Saccharum;* the use of brown sugar and molasses being replaced by the employment of an officinal syrup of known strength. (See *Syrupus.*) The London Pharmacopœia recognises white sugar and molasses; and the Edinburgh and Dublin Colleges admit not only these, but also brown sugar.

Commercial History. Sugar has been known from the earliest ages, and was originally obtained from Asia. About the period of the Crusades, the Venetians brought it to Europe; but at that time it was so scarce as to be used exclusively as a medicine. Upon the discovery of the Cape of Good-Hope and the maritime route to the East Indies, the commerce in sugar passed into the hands of the Portuguese. Subsequently, the cultivation of the cane was extended to Arabia, Egypt, Sicily, Spain, and the Canaries, and finally, upon the discovery of the new world, to America, where it was pursued with the greatest success, and continues to be so to the present day. In America it is produced most abundantly in the West Indies, which supply the greater part of the consumption of Europe, little comparatively being taken thither from Brazil or the East Indies. The consumption of the United States is more than half supplied by Louisiana and some of the neighbouring States. The crop of sugar of Louisiana, in 1847, was estimated at 240,000 hogsheads; in 1853, at 322,000. The crop of Cuba for the latter year is supposed to have reached 600,000 hogsheads. Within a recent period, our planters have introduced into Louisiana the variety of cane called the Otaheite cane, which is hardier and more productive than the common cane, and better suited to the climate of our Southern States.

Properties. Sugar, in a pure state, is a solid of a peculiar grateful taste, permanent in the air, phosphorescent by friction, and of the sp. gr. 1·6. It dissolves readily in half its weight of cold water, and to almost an unlimited extent in boiling water. The solution, when thick and ropy, is called *syrup*. An aqueous solution of sugar possesses the property of dissolving a large quantity of hydrate

of lime, forming a compound, called *syrup of lime*. When a concentrated syrup is gently heated, and spirit added to it, the liquid, on cooling, forms white semi-transparent crystals of hydrated sugar, having the shape of oblique four-sided prisms, and called *sugar candy*. Sugar is nearly insoluble in absolute alcohol, but dissolves in four times its weight of boiling alcohol of the sp. gr. 0·83. When heated to 365°, it melts into a viscid, colourless liquid, which, on being suddenly cooled, forms a transparent amorphous mass, called *barley sugar*. At a higher temperature (between 400° and 420°) it loses two eqs. of water, and is converted into a black porous mass, having a high lustre like anthracite, called *caramel*. At a still higher heat it yields combustible gases, carbonic acid, empyreumatic oil, and acetic acid; and there remains one-fourth of its weight of charcoal, which burns without residue. Sugar renders the fixed and volatile oils to a certain extent miscible with water, and forms with the latter an imperfect combination, called in pharmacy *oleo-saccharum*. When in solution, it is not precipitated by subacetate of lead, a negative property which distinguishes it from most other organic principles.

Cane sugar may be distinguished from grape sugar by the combined action of sulphate of copper and caustic potassa. If solution of cane sugar be mixed with solution of sulphate of copper, and potassa be added in excess, a deep-blue liquid is obtained, which, on being heated, lets fall a little red powder after a time. Solution of grape sugar, similarly treated, yields, when heated, a copious greenish precipitate, which rapidly changes to scarlet, and eventually to dark-red. Dr. Donaldson's test for sugar in the *animal fluids* is formed of five parts of carbonate of soda, five of caustic potassa, six of bitartrate of potassa, four of sulphate of copper, and thirty-two of distilled water. A few drops of this solution, being added to an animal fluid, and the mixture heated over a spirit-lamp, a yellowish-green colour is developed, if sugar be present.

Action of Acids and Alkalies, &c. The mineral acids act differently on cane sugar, according as they are concentrated or dilute. Strong nitric acid, with the assistance of heat, converts it into oxalic acid. (See *Oxalic Acid* in the Appendix.) The same acid, when weak, converts it into *saccharic acid*, confounded by Scheele with malic acid. Concentrated muriatic or sulphuric acid chars it. Treated, in fine powder, with a mixture of sixteen parts of sulphuric and eight of nitric acid, cooled to the temperature of 60°, it is converted, in a few seconds, into a pasty substance, which, after having been washed with cold water and dissolved in alcohol, furnishes, on the addition of an excess of carbonate of potassa to the alcoholic solution, a peculiar explosive and inflammable substance, resembling common rosin in its physical properties, and, like it, insoluble in water, but soluble in alcohol, ether, and the volatile oils. (*L. Thompson.*) Diluted muriatic acid, when boiled with cane sugar, converts it into a solid, brown, gelatinous mass. Weak sulphuric acid, by a prolonged action at a high temperature, converts cane sugar, first into uncrystallizable sugar, afterwards into grape sugar, and finally into two substances, analogous to ulmin and ulmic acid, called *sacchulmin* and *sacchulmic acid*. Vegetable acids are supposed to act in a similar way. If the boiling be prolonged for several days in open vessels, oxygen is absorbed, and, besides these two substances, formic acid is generated. Soubeiran admits the change of the uncrystallizable into grape sugar, but attributes it to a molecular transformation of the sugar, independently of the action of the acid; as, according to his observation, the conversion takes place only after rest. In confirmation of his views, this chemist states that he found the same changes to be produced by boiling sugar with water alone.

Cane sugar unites with the alkalies and some of the alkaline earths, forming definite combinations which render the sugar less liable to change. It also unites with protoxide of lead. Boiled for a long time with aqueous solutions of

potassa, lime, or baryta, the liquid becomes brown, formic acid is produced, and two new acids are generated; one brown or black and insoluble in water, called *melassic acid*, the other colourless and very soluble, named *glucic acid*.

The account above given of the action of acids and alkalies on sugar explains the way in which lime acts in the manufacture and refining of sugar. The acids, naturally existing in the saccharine juice, have the effect of converting the cane sugar into uncrystallizable sugar, by which a loss of the former is sustained. The use of lime, by neutralizing these acids, prevents this result. An excess of lime, however, must be carefully avoided; as it injures the product of cane sugar both in quantity and quality. The change in the sugar which precedes fermentation points to the necessity of operating before that process sets in; and hence the advantage of grinding the canes immediately after they are cut, and boiling the juice with the least possible delay.

The following is a description of the several forms of officinal sugar.

Purified or *white sugar*, as obtained on a large scale, is in concrete, somewhat porous masses, called loaves, consisting of an aggregate of small crystalline grains. When carefully refined, it is brittle and pulverulent, perfectly white, inodorous, and possessed of the pure saccharine taste. Cane sugar is sometimes adulterated with starch sugar, which may be detected by adding to a concentrated solution of the suspected sugar, first a small portion of fused potassa, and afterwards, at the boiling temperature, a few drops of nitrate of cobalt. This test, if the sugar be pure, will produce a violet-blue precipitate, a reaction prevented by the presence of a small proportion of starch sugar. (*Dr. G. Reich.*)

Unpurified or *brown sugar* is in the form of a coarse powder, more or less moist and sticky, consisting of shining crystalline grains, intermixed with lumps, having an orange-yellow colour, more or less deep, a sweet, cloying taste, and heavy peculiar smell. It varies very much in quality. The best sort is nearly dry, in large sparkling grains of a clear yellow colour, and possesses much less smell than the inferior kinds. It consists of cane sugar, associated with variable quantities of gummy and colouring matter, and a small proportion of lime and tannic acid. By keeping, it becomes soft and gummy, and less sweet; a change attributed to the lime.

Molasses is of two kinds, the West India and sugar house. *West India molasses* is a black ropy liquid, of a peculiar odour, and sweet empyreumatic taste. When mixed with water and the skimmings of the vessels used in the manufacture of sugar, it forms a liquor, which, when fermented and distilled, yields rum. *Sugar house molasses* has the same general appearance as the West India. It is, however, thicker, and has a different flavour. Its sp. gr. is about 1·4, and it contains about 75 per cent. of solid matter. Both kinds of molasses consist of uncrystallizable sugar, more or less cane sugar which has escaped separation in the process of manufacture or refining, and gummy and colouring matter. When the molasses from cane sugar is treated with a boiling, concentrated solution of bichromate of potassa, and boiled, a violent reaction takes place, and the liquid becomes green; but if it be adulterated with only an eighth of starch sugar molasses, the reaction is prevented, and the colour is not changed. (*Dr. G. Reich.*)

Composition. The following formulas express the composition of the different varieties of sugar, so far as known. Cane sugar, $C_{12}H_{11}O_{11}$. Cane sugar, as it exists in combination with two eqs. of protoxide of lead (caramel? anhydrous sugar?), $C_{12}H_9O_9$. Grape sugar, $C_{12}H_{14}O_{14}$. Grape sugar and uncrystallizable sugar, dried at 212°, $C_{12}H_{12}O_{12}$. Sorbin, $C_{12}H_{12}O_{12}$. (*Pelouze.*) The theory of the conversion of sugar, during the vinous fermentation, into alcohol and carbonic acid, will be explained under *absolute alcohol*. (See *Alcohol*, Ed., Dub., in the second part of this work.)

Med. and Pharm. Uses, &c. The uses of sugar as an aliment and condiment

are numerous. It is nutritious, but not capable of supporting life when taken exclusively as aliment, on account of the absence of nitrogen in its composition. It is a powerful antiseptic, and is beginning to be used for preserving meat and fish; for which purpose it possesses the advantage of acting in a much less quantity than is requisite of common salt, and of not altering the taste, nor impairing the nutritious qualities of the aliment. Prof. Marchand has ascertained that a solution of sugar has no action on the teeth out of the body. It may hence be inferred that the popular notion that sugar is injurious to the teeth is unfounded.

The medical properties of *sugar* are those of a demulcent, and as such it is much used in catarrhal affections, in the form of candy, syrup, &c. According to M. Provençal, it acts as a powerful antaphrodisiac, given in the quantity of a pound or more daily, dissolved in a quart of cold water. In pharmacy it is employed to render oils miscible with water, to cover the taste of medicines, to give them consistency, to preserve them from change, and to protect from oxidation certain ferruginous preparations. Accordingly it enters into the composition of several infusions and mixtures, of nearly all the syrups and confections, and of all the troches. It is directed by the Edinburgh College for purifying the commercial sulphuric acid from nitrous acid. *Molasses* is used to give the proper consistence to pills, in ten London formulæ, six Dublin, and one Edinburgh. It is well fitted for forming pills, preserving them soft and free from mouldiness, on account of its retentiveness of moisture and antiseptic qualities.

SACCHARUM LACTIS. *Dub.*

Sugar of Milk.

Lactose; Sucre de lait, *Fr.*; Milchzucker, *Germ.*

Sugar of milk, or *lactin*, is found only in milk, of which it forms about five per cent. (*Boussingault.*) It is manufactured largely in Switzerland as an article of food. In preparing it, milk is first coagulated by the addition of a little dilute sulphuric acid, and the resulting *whey* is evaporated to a syrupy consistence, and set aside for several weeks, in a cool place, to crystallize. The crystals, which constitute the sugar of milk, are then decolorized by animal charcoal, and repeated crystallizations.

Sugar of milk is a hard, somewhat gritty, white substance, crystallized in four-sided prisms, and possessing a slightly sweet taste. In commerce it sometimes occurs in cylindrical masses, in the axis of which is a cord, around which the crystals have been deposited. It dissolves slowly in six parts of cold and three of boiling water, without forming a syrup. It is insoluble in ether, and but slightly soluble in alcohol. Its sp. gr. is 1·54. It is not susceptible of the vinous fermentation by the direct influence of yeast, but, after the action of dilute acids, which first convert it into grape sugar, it is capable of furnishing a spirituous liquor. It is well known that both mares' and cows' milk, after becoming sour, is capable of forming an intoxicating drink by fermentation. By the action of nitric acid, sugar of milk is converted into mucic (saclactic) acid. When anhydrous it consists of $C_{24}H_{19}O_{19}$; when crystallized, of $C_{24}H_{19}O_{19}+5HO$.

Sugar of milk has been proposed by Dr. Turnbull, of England, as a non-nitrogenous article of diet, in consumption and other pulmonary diseases. Dr. Ruschenberger used it with good effect as nourishment in a case of extreme irritability of stomach, following profuse loss of blood from menorrhagia. (*Trans. of the Phil. Col. of Phys.*, ii. 48.) B.

SAGAPENUM. *Lond.*

Sagapenum.

An uncertain plant. The gum resin. *Lond.*

Sagapenum, *Fr.;* Sagapen, *Germ.;* Sagapeno, *Ital., Span.;* Sugbeenuj, *Arab.*

All that is known in relation to the source of this gum-resin is, that it is the concrete juice of a plant, probably umbelliferous, growing in Persia. The plant is conjectured to be a species of Ferula, and Willdenow supposed it to be *F. Persica*, but without sufficient evidence. The drug is brought from Alexandria, Smyrna, and other ports of the Levant.

It is in irregular masses, composed of agglutinated fragments, slightly translucent, of a brownish-yellow, olive, or reddish-yellow colour externally, paler internally, brittle, of a consistence somewhat resembling that of wax, and often mixed with impurities, especially with seeds more or less entire. An inferior variety is soft, tough, and of uniform consistence. It has an alliaceous odour, less disagreeable than that of assafetida, and a hot, nauseous, bitterish taste. It softens and becomes tenacious by the heat of the hand. The effect of time and exposure is to harden and render it darker. It is inflammable, burning with a white flame and much smoke, and leaving a light spongy charcoal. Pure alcohol and water dissolve it partially, diluted alcohol almost entirely. Distilled with water it affords a small quantity of volatile oil; and the water is strongly impregnated with its flavour. According to Pelletier, it contains, in 100 parts, 54·26 of resin, 31·94 of gum, 1·0 of bassorin, 0·60 of a peculiar substance, 0·40 of acidulous malate of lime, and 11·80 of volatile oil including loss. Brandes found 3 73 per cent. of volatile oil. This is pale-yellow, very fluid, lighter than water, and of a disagreeable alliaceous odour.

Medical Properties and Uses. Sagapenum is a moderate stimulant, resembling assafetida, but much inferior, and usually considered as intermediate between that gum-resin and galbanum. It has been given as an emmenagogue and antispasmodic in amenorrhœa, hysteria, chlorosis, &c., but is now seldom used. It was known to the ancients; and Dioscorides speaks of it as being derived from Media. The dose is from ten to thirty grains, and may be given in pill or emulsion. Sagapenum is also considered discutient, and has been occasionally applied externally, in the form of plaster, to indolent tumours.

SAGO. *U.S., Lond., Ed., Dub.*

Sago.

The prepared fecula of the pith of Sagus Rumphii. *U. S.* Sagus lævis, S. Rumphii, and other species of palms. The fecula of the stem. *Lond.* Farina from the interior of the trunk of various Palmaceæ and species of Cycas. *Ed.* Cycas circinalis and other species of Cycas, and various Palmaceæ. The farina from the interior of the trunk. *Dub.*

Sagou, *Fr.;* Sago, *Germ., Ital.;* Sagu, *Span.*

Numerous trees, inhabiting the islands and coasts of the Indian Ocean, contain a farinaceous pith, which is applied to the purposes of nutriment by the natives. Such are *Sagus Rumphii*, *Sagus lævis*, *Sagus Ruffia*, *Saguerus Rumphii*, and *Phœnix farinifera*, belonging to the family of *palms;* and *Cycas circinalis*, *Cycas revoluta*, and *Zamia lanuginosa*, belonging to the *Cycadaceæ*. Of these *Sagus Rumphii*, *Sagus lævis*, and *Saguerus Rumphii* probably contribute

to furnish the sago of commerce. Crawford, in his History of the Indian Archipelago, states that it is derived exclusively from *Metroxylon Sagu*, identical with *Sagus Rumphii;* but Roxburgh ascribes the granulated sago to *S. lævis*, and one of the finest kinds is said by Dr. Hamilton to be produced by the *Saguerus Rumphii* of Roxburgh. The farinaceous product of the different species of Cycas, sometimes called *Japan sago*, does not enter into general commerce.

Sagus. *Sex. Syst.* Monœcia Hexandria.—*Nat. Ord.* Palmaceæ.

Gen. Ch. Common spathe one-valved. *Spadix* branched. Male. *Calyx* three-leaved. *Corolla* none. *Filaments* dilated. Female. *Calyx* three-leaved, with two of the leaflets bifid. *Corolla* none. *Style* very short. *Stigma* simple. *Nut* tessellated-imbricated, one-seeded. *Willd.*

Sagus Rumphii. Willd. *Sp. Plant.* iv. 404; Carson, *Illust. of Med. Bot.* ii. 44, pl. 88. The *sago palm* is one of the smallest trees of the family to which it belongs. Its extreme height seldom exceeds thirty feet. The trunk is proportionably very thick, quite erect, cylindrical, covered with the remains of the old leafstalks, and surrounded by a beautiful crown of foliage, consisting of numerous very large, pinnate leaves, extending in every direction from the summit, and curving gracefully downwards. From the basis of the leaves proceed long, divided and subdivided flower and fruit-bearing spadices, the branches of which are smooth. The fruit is a roundish nut, covered with a checkered imbricated coat, and containing a single seed.

The tree is a native of the East India islands, growing in the Peninsula of Malacca, Sumatra, Borneo, Celebes, the Moluccas, and a part of New Guinea. It flourishes best in low and moist situations. Before attaining maturity, the stem consists of a shell usually about two inches thick, filled with an enormous volume of spongy medullary matter like that of elder. This is gradually absorbed after the appearance of fruit, and the stem ultimately becomes hollow. The greatest age of the tree is not more than thirty years. At the proper period of its growth, when the medullary matter is fully developed, and has not yet begun to diminish, the tree is felled, and the trunk cut into billets six or seven feet long, which are split in order to facilitate the extraction of the pith. This is obtained in the state of a coarse powder, which is mixed with water in a trough, having a sieve at the end. The water, loaded with farina, passes through the sieve, and is received in convenient vessels, where it is allowed to stand till the insoluble matter has subsided. It is then strained off; and the farina which is left may be dried into a kind of meal, or moulded into whatever shape may be desired. For the consumption of the natives it is usually formed into cakes of various sizes, which are dried, and extensively sold in the islands. The commercial sago is prepared by forming the meal into a paste with water, and rubbing it into grains. It is produced in the greatest abundance in the Moluccas, but of the finest quality on the eastern coast of Sumatra. The Chinese of Malacca refine it so as to give the grains a fine pearly lustre. Malcolm states that it is also refined in large quantities at Singapore. In this state it is called *pearl sago*, and is in great repute. It is said that not less than five or six hundred pounds of sago are procured from a single tree. (*Crawford.*)

Pearl sago is that which is now generally used. It is in small grains, about the size of a pin's head, hard, whitish, of a light-brown colour, in some instances translucent, inodorous, and with little taste. It may be rendered perfectly white by a solution of chloride of lime. *Common sago* is in larger and browner grains, of more unequal size, of a duller aspect, and frequently mixed with more or less of a dirty-looking powder.

Sago meal is imported into England from the East Indies; but we have met with none in the markets of this country. It is in the form of a fine amylaceous powder, of a whitish colour, with a yellowish or reddish tint, and of a faint but somewhat musty odour.

Common sago is insoluble in cold water, but by long boiling unites with that liquid, becoming at first soft and transparent, and ultimately forming a gelatinous solution. Pearl sago is partially dissolved by cold water, probably owing to heat used in its preparation. Chemically considered, it has the characters of starch. Under the microscope the granules of sago meal appear oval or ovate, and often truncated so as to be more or less mullar-shaped. Many of them are broken, and in most the surface is irregular or tuberculated. They exhibit upon their surface concentric rings, which, however, are much less distinct than in potato starch. The hilum is circular when perfect, and cracks either with a single slit, or a cross, or in a stellate manner. The granules of pearl sago are of the same form, but are all ruptured, and exhibit only indistinct traces of the annular lines, having been altered in the process employed in preparing them. Those of the common sago are very similar to the particles of sago meal, except that they are perhaps rather less regular and more broken. (*Pereira.*)

Potato starch is sometimes prepared in Europe so as to resemble bleached pearl sago, for which it is sold. But, when examined under the microscope, it exhibits larger granules, which are also more regularly oval or ovate, smoother, less broken, and more distinctly marked with the annular rugæ than those of sago; and the hilum often cracks with two slightly diverging slits.

Sago is used exclusively as an article of diet. Being nutritive, easily digestible, and wholly destitute of irritating properties, it is frequently employed in febrile cases, and in convalescence from acute disorders, in the place of richer and less innocent food. It is given in the liquid state, and in its preparation care should be taken to boil it long in water, and stir it diligently, in order that the grains may be thoroughly dissolved. Should any portion remain undissolved, it should be separated by straining; as it might offend a delicate stomach. A tablespoonful to the pint of water is sufficient for ordinary purposes. The solution may be seasoned with sugar and nutmeg or other spice, and with wine, where these are not contra-indicated. W.

SALIX. *U. S. Secondary.*

Willow.

The bark of Salix alba. *U. S.*

Off. Syn. SALICIS CORTEX. Bark of Salix Caprea. *Ed.*

Ecorce de saule, *Fr.;* Weidenrinde, *Germ.;* Corteccia di salcio, *Ital.;* Corteza de sauce, *Span.*

SALIX. *Sex. Syst.* Dicœcia Diandria.—*Nat. Ord.* Salicaceæ.

Gen. Ch. MALE. *Amentum* cylindrical. *Calyx* a scale. *Corolla* none. *Glands* of the base nectariferous. FEMALE. *Amentum* cylindrical. *Calyx* a scale. *Corolla* none. *Style* two-cleft. *Capsule* one-celled, two-valved. *Seeds* downy. *Willd.*

This is a very extensive genus, comprising, according to Nuttall, not less than one hundred and thirty species, which, with very few exceptions, are natives of Europe, and of the northern and temperate parts of North America. Though most of them are probably possessed of similar medical properties, only two are now recognised as officinal in the Pharmacopœias of the U. States and Great Britain; viz., *S. alba* and *S. caprea;* of which *Salix alba* only has been introduced into this country. *S. Russelliana*, which has been introduced from Europe, is said by Sir James Smith to be the most valuable species. *S. purpurea*, which is a European species, is said by Lindley to be the most bitter, and *S. pentandra* is preferred by Nees von Esenbeck. Many native species are in all probability equally active with the foreign; but they have not been sufficiently tried in regular practice to admit of a positive decision. The younger Michaux

speaks of *S. nigra* or *black willow* as affording in its root a strong bitter, used in the country as a preventive and cure of intermittents. In consequence of the pliability of the young branches or twigs, the willow is well adapted for the manufacture of baskets and other kinds of wicker-work; and several species, native and introduced, are employed for this purpose in the United States. *S. Babylonica* or weeping willow is a favourite ornamental tree. The degree of bitterness in the bark is probably the best criterion of the value of the different species.

Salix alba. Willd. *Sp. Plant.* iv. 710; Smith, *Flor. Brit.* 1071. The common European or white willow is twenty-five or thirty feet in height, with numerous round spreading branches, the younger of which are silky. The bark of the trunk is cracked and brown, that of the smaller branches smooth and greenish. The leaves are alternate, upon short petioles, lanceolate, pointed, acutely serrate with the lower serratures glandular, pubescent on both sides, and silky beneath. There are no stipules. The flowers appear at the same time with the leaves. The *amenta* are terminal, cylindrical, and elongated, with elliptical-lanceolate, brown, pubescent scales. The stamens are two in number, yellow, and somewhat longer than the scales; the style is short; the stigmas two-parted and thick. The capsule is nearly sessile, ovate, and smooth. The white willow has been introduced into this country from Europe, and is now very common. It flowers in April and May; and the bark is easily separable throughout the summer.

That obtained from the branches rolls up when dried into the form of a quill, has a brown epidermis, is flexible, fibrous, and of difficult pulverization. Willow bark has a feebly aromatic odour, and a peculiar bitter astringent taste. It yields its active properties to water, with which it forms a reddish-brown decoction. Pelletier and Caventou found among its ingredients tannin, resin, a bitter yellow colouring matter, a green fatty matter, gum, wax, lignin, and an organic acid combined with magnesia. The proportion of tannin is so considerable that the bark has been used for tanning leather. A crystalline principle has also been obtained from it, which, having the medical virtues of the willow, has received the name of *salicin*. When pure, it is in white, shining, slender crystals, inodorous, but very bitter, with the peculiar flavour of the bark. It is soluble in cold water, much more so in boiling water, soluble in alcohol, and insoluble in ether and the oil of turpentine. It neutralizes neither acids nor salifiable bases; and is not precipitated by any reagent. Concentrated sulphuric acid decomposes it, receiving from it an intense and permanent bright-red colour, and producing a new compound called *rutulin*. Muriatic and dilute sulphuric acids convert it into grape-sugar, and a white, tasteless, insoluble powder named *saliretin*. Distilled with bichromate of potassa and sulphuric acid, it yields, among other products, a volatile oleaginous fluid, identical with one of the components of oil of spiræa, and, from its acid properties, denominated *salicylous acid*. This is considered by Dumas as consisting of a peculiar compound radical called *salicyle* and hydrogen. The formula of salicin is $C_{42}H_{29}O_{22}$. (*Turner's Chemistry.*) The honour of its discovery is claimed by Buchner, of Germany, and Fontana and Rigatelli, of Italy; but M. Leroux, of France, deserves the credit of having first accurately investigated its properties. Braconnot procured it by adding subacetate of lead to a decoction of the bark, precipitating the excess of lead by sulphuric acid, evaporating the colourless liquid which remains, adding near the end of the process a little animal charcoal previously washed, and filtering the liquor while hot. Upon cooling it deposits the salicin in a crystalline form. (*Journ. de Chimie Médicale*, Jan. 1831.) The following is the process of Merck. A boiling concentrated decoction of the bark is treated with litharge until it becomes nearly colourless. Gum, tannin, and extractive matter, which would impede the crystallization of the salicin, are thus removed from the liquid;

while a portion of the oxide is dissolved in union probably with the salicin. To separate this portion of oxide, sulphuric acid is first added and then sulphuret of barium, and the liquor is filtered and evaporated. Salicin is deposited, and may be purified by repeated solution and crystallization. (*Turner's Chemistry.*) Erdmann has given another process. Sixteen ounces of the bark are macerated for twenty-four hours in four quarts of water mixed with two ounces of lime, and the whole is then boiled for half an hour. The process is repeated with the residue. The decoctions having been mixed, and allowed to become clear by subsidence, the liquor is poured off, concentrated to a quart, then digested with eight ounces of ivory-black, filtered, and evaporated to dryness. The extract is exhausted by spirit containing 28 per cent. of alcohol, and the tincture evaporated so that the salicin may crystallize. This is purified by again dissolving, treating with ivory-black, and crystallizing. (*Christison's Dispensatory.*) Merck obtained 251 grains from 16 ounces of the bark and young twigs of *Salix helix*, and Erdmann 300 grains from the same quantity of the bark of *Salix pentandra*. It may probably be obtained from any of the willow barks having a bitter taste. Braconnot procured it from various species of Populus, particularly *P. tremula* or European aspen.

Medical Properties and Uses. The bark of the willow is tonic and astringent, and has been employed as a substitute for Peruvian bark, particularly in intermittent fever. It has attracted much attention from the asserted efficacy of salicin in the cure of this complaint. There seems to be no room to doubt, from the testimony of numerous practitioners in France, Italy, and Germany, that this principle has the property of arresting intermittents; though the ascription to it of equal efficacy with the sulphate of quinia was certainly premature. The bark may be employed in substance or decoction, in the same doses and with the same mode of preparation as cinchona. The dose of salicin is from two to eight grains, to be so repeated, that from twenty to forty grains may be taken daily, or in the interval between the paroxysms of an intermittent. Magendie has seen fevers cut short in one day by three doses of six grains each. The decoction of willow has been found beneficial as an external application to foul and indolent ulcers. W.

SALVIA. *U. S. Secondary.*

Sage.

The leaves of Salvia officinalis. *U. S.*

Sauge, *Fr.;* Salbey, *Germ.;* Salvia, *Ital., Span.*

Salvia. *Sex. Syst.* Diandria Monogynia.—*Nat. Ord.* Lamiaceæ or Labiatæ. *Gen. Ch. Corolla* unequal. *Filaments* affixed transversely to a pedicel. *Willd.*

Salvia officinalis. Willd. *Sp. Plant.* i. 129; Woodv. *Med. Bot.* p. 352, t. 127. Common garden sage is a perennial plant, about two feet high, with a quadrangular, pubescent, branching, shrubby stem, furnished with opposite, petiolate, ovate-lanceolate, crenulate, wrinkled leaves, of a grayish-green colour, sometimes tinged with red or purple. The flowers are blue, variegated with white and purple; and are disposed on long terminal spikes, in distant whorls, each composed of few flowers, and accompanied with ovate, acute, deciduous bractes. The calyx is tubular and striated, with two lips, of which the upper has three acute teeth, the under two. The corolla is tubular, bilabiate, ringent, with the upper lip concave, the lower divided into three rounded lobes, of which the middle is the largest. The filaments are supported upon short pedicels, to which they are affixed transversely at the middle.

Sage grows spontaneously in the South of Europe, and is cultivated abundantly in our gardens. There are several varieties, differing in the size and colour

of their flowers, but all possessed of the same medical properties. The flowering period is in June, at which time the plant should be cut and dried in a shady place. The leaves are the officinal portion.

Both these and the flowering summits have a strong fragrant odour, and a warm, bitterish, aromatic, somewhat astringent taste. They abound in a volatile oil, which may be obtained separate by distillation with water, and contains a considerable proportion of camphor. Sulphate of iron strikes a black colour with their infusion.

Medical Properties and Uses. Sage unites a slight degree of tonic power and astringency with aromatic properties. By the ancients it was highly esteemed; but it is at present little used internally, except as a condiment. In the state of infusion it may be given in debility of the stomach with flatulence, and is said to have been useful in checking the sweats of hectic fever. But its most useful application is as a gargle in inflammation of the throat, and relaxation of the uvula. For this purpose it is usually employed in infusion, with honey and alum, or vinegar. The dose of the powdered leaves is from twenty to thirty grains. The infusion is prepared by macerating an ounce of the leaves in a pint of boiling water, of which two fluidounces may be administered at once. When intended merely as a pleasant drink in febrile complaints, or to allay nausea, the maceration should continue but a very short time, so that all the bitterness of the leaves may not be extracted.

Two other species of salvia—*S. pratensis* and *S. Sclarea*—are ranked among officinal plants in Europe. The latter, which is commonly called *clarry*, has been introduced into our gardens. Their medical properties are essentially the same as those of the common sage; but they are less agreeable, and are not much used. In Europe, the leaves of *S. Sclarea* are said to be introduced into wine in order to impart to it a muscadel taste. W.

Sambucus. *Sex. Syst.* Pentandria Trigynia.—*Nat. Ord.* Caprifoliaceæ.

Gen. Ch. Calyx five-parted. *Corolla* five-cleft. *Berry* three-seeded. *Willd.*

Sambucus Canadensis. Willd. *Sp. Plant.* i. 1494. Our indigenous *common elder* is a shrub from six to ten feet high, with a branching stem, which is covered with a rough gray bark, and contains a large spongy pith. The small branches and the leafstalks are very smooth. The leaves are opposite, pinnate, sometimes bipinnate, and composed usually of three or four pairs of oblong-oval, acuminate, smooth, shining, deep-green leaflets, the midribs of which are somewhat pubescent. The flowers are small, white, and disposed in loose cymes, having about five divisions. The berries are small, globular, and deep-purple when ripe.

The shrub grows in low moist grounds, along fences, and on the borders of small streams, in all parts of the United States, from Canada to Carolina. It flowers from May to July, and ripens its berries early in autumn. The flowers, which are the officinal portion, have a somewhat aromatic, though rather heavy odour. The berries as well as other parts of the plant are employed in domestic practice, and answer the same purposes as the corresponding parts of the European elder, to which this species bears a close affinity.

Sambucus nigra. Willd. *Sp. Plant.* i. 1495; Woodv. *Med. Bot.* p. 596, t. 211. The common elder of Europe differs from the American most obviously in its size, which approaches to that of a small tree. The stem is much branched to-

wards the top, and has a rough whitish bark. The leaves are pinnate, consisting usually of five oval, pointed, serrate leaflets, four of which are in opposite pairs, and the fifth terminal. The flowers are small, whitish, and in five-parted cymes. The berries are globular, and of a blackish-purple colour when ripe.

The *flowers* have a peculiar sweetish odour, which is strong in their recent state, but becomes feeble by drying. Their taste is bitterish. They yield their active properties to water by infusion, and when distilled give over a small proportion of volatile oil, which on cooling assumes a butyraceous consistence. Water distilled from them contains an appreciable portion of ammonia. The *berries* are nearly inodorous, but have a sweetish, acidulous taste, dependent on the saccharine matter and malic acid which they contain. Their expressed juice is susceptible of fermentation, and forms a vinous liquid used in the North of Europe. It is coloured violet by alkalies, and bright red by acids; and the colouring matter is precipitated blue by acetate of lead. The *inner bark* is without smell. Its taste is at first sweetish, afterwards slightly bitter, acrid, and nauseous. Both water and alcohol extract its virtues, which are said to reside especially in the green layer between the liber and epidermis. According to Simon, the active principle of the inner bark of the root is a soft resin, which may be obtained by exhausting the powdered bark with alcohol, filtering the tincture, evaporating to the consistence of syrup, then adding ether, which dissolves the active matter, and finally evaporating to the consistence of a thick extract. Of this, twenty grains produce brisk vomiting and purging. (*Annal. der Pharm.*, xxxi. 262.) The bark, analyzed by Kramer, yielded an acid called by him *viburnic acid*, but which has proved to be the *valerianic*, traces of volatile oil, albumen, resin, an acid sulphurous fat, wax, chlorophylle, tannic acid, grape-sugar, gum, extractive, starch, pectin, and various alkaline and earthy salts. (*Chem. Gaz.*, May, 1846, from *Archiv. der Pharm.*)

Medical Properties and Uses. The flowers are gently excitant and sudorific, but are seldom used except externally, as a discutient in the form of poultice, fomentation, or ointment. The berries are diaphoretic and aperient; and their inspissated juice has enjoyed some reputation as a remedy in rheumatic, gouty, eruptive, and syphilitic affections. Its dose as an alterative diaphoretic is one or two drachms, as a laxative half an ounce or more. The inner bark is a hydragogue cathartic, acting also as an emetic in large doses. It has been employed in dropsy, and as an alterative in various chronic diseases. An ounce may be boiled with two pints of water to a pint, and four fluidounces of the decoction given for a dose. It is also sometimes used in vinous infusion. The leaves are not without activity, and the young leaf-buds are said to be a violent and even unsafe purgative. The juice of the root has been highly recommended in dropsy as a hydragogue cathartic, sometimes acting as an emetic, in the dose of a tablespoonful, repeated every day, or less frequently if it act with violence.

SANGUINARIA. *U. S.*

Bloodroot.

The rhizoma of Sanguinaria Canadensis. *U. S.*

Sanguinaria. *Sex. Syst.* Polyandria Monogynia. — *Nat. Ord.* Papaveraceæ.

Gen. Ch. Calyx two-leaved. *Petals* eight. *Stigma* sessile, two-grooved. *Capsule* superior, oblong, one-celled, two-valved, apex attenuated. *Receptacles* two, filiform, marginal. *Nuttall.*

Sanguinaria Canadensis. Willd. *Sp. Plant.* ii. 1140; Bigelow, *Am. Med. Bot.* i. 75; Barton, *Med. Bot.* i. 31. The *bloodroot*, or, as it is sometimes called, *puccoon*, is an herbaceous perennial plant. The root (rhizoma) is horizontal, abrupt,

often contorted, about as thick as the finger, two or three inches long, fleshy, of a reddish-brown colour on the outside, and brighter red within. It is furnished with numerous slender radicles, and makes offsets from the sides, which succeed the old plant. From the end of the root arise the scape and leafstalks, surrounded by the large sheaths of the bud. These spring up together, the folded leaf enveloping the flower-bud, and rolling back as the latter expands. The leaf, which stands upon a long channeled petiole, is reniform, somewhat heart-shaped, deeply lobed, smooth, yellowish-green on the upper surface, paler or glaucous on the under, and strongly marked by orange-coloured veins. The scape is erect, round, and smooth, rising from a few inches to a foot in height, and terminating in a single flower. The calyx is two-leaved and deciduous. The petals, varying from seven to fourteen, but usually about eight in number, are spreading, ovate, obtuse, concave, mostly white, but sometimes slightly tinged with rose or purple. The stamens are numerous, with yellow filaments shorter than the corolla, and orange oblong anthers. The germ is oblong and compressed, and supports a sessile, persistent stigma. The capsule is oblong, acute at both ends, two-valved, and contains numerous oval, reddish-brown seeds. The whole plant is pervaded by an orange-coloured sap, which flows from every part when broken, but is of the deepest colour in the root.

The bloodroot is one of the earliest and most beautiful spring flowers of North America. It grows abundantly throughout the whole United States, delighting in loose rich soils, and shady situations, and flowering in March and April. After the fall of the flower, the leaves continue to grow, and, by the middle of summer, have become so large as to give the plant an entirely different aspect. All parts of the plant are active, but the root only is officinal.

This, when dried, is in pieces from one to three inches long, from a quarter to half an inch or more in thickness, flattened, much wrinkled and twisted, often furnished with abrupt offsets and numerous short fibres, of a reddish-brown colour externally, with a spongy uneven fracture, the surface of which is at first bright-orange, but becomes of a dull-brown by long exposure. The colour of the powder is a brownish orange-red. Sanguinaria has a faint narcotic odour, and a bitterish very acrid taste, the pungency of which remains long in the mouth and fauces. It yields its virtues to water and alcohol. The late Dr. Dana, of New York, obtained from it a peculiar alkaline principle, denominated by him *sanguinarina*, upon which the acrimony, and perhaps the medical virtues of the root depend. It may be procured, according to Dana, by infusing the finely powdered root in hot water or diluted muriatic or acetic acid, precipitating with water of ammonia, collecting the precipitated matter, boiling it in water with pure animal charcoal, filtering off the water, exposing the residue left upon the filter to the action of alcohol, and finally evaporating the alcoholic solution. (*Ann. Lyc. of Nat. Hist., New York*, ii. 250.) It may also be conveniently procured by a process similar to that employed by Probst for obtaining chelerythrin from celandine. This consists in forming a strong ethereal tincture of the root; passing through this muriatic acid gas, drying the precipitated muriate which is insoluble in ether, dissolving it in hot water, filtering, precipitating by ammonia, drying the precipitate, dissolving it in ether, decolorizing by animal charcoal, again precipitating by means of muriatic acid gas, and decomposing the muriate as before. (*Chem. Gaz.*, i. 145.) Sanguinarina, thus obtained, is a white pearly substance, of an acrid taste, very sparingly soluble in water, soluble in ether, and very soluble in alcohol. With the acids it forms salts soluble in water, all of which have some shade of red, crimson, or scarlet, and form beautiful red solutions. They are acrid and pungent to the taste, particularly the muriate and acetate. From these facts it would appear that the red colour and acrid properties of the bloodroot may be owing to the presence of some native salt of sanguinarina, which is de-

composed by ammonia in the separation of the organic alkali. The formula of sanguinarina is $NC_{37}H_{16}O_8$. A principle has been extracted from bloodroot by Riegel analogous to the porphyroxin found by Merck in opium. (*Chem. Gaz.*, iv. 198.) The virtues of the root are said to be rapidly deteriorated by time.

Medical Properties and Uses. Sanguinaria is an acrid emetic, with stimulant and narcotic powers. In small doses it excites the stomach, and accelerates the circulation; more largely given, produces nausea and consequent depression of the pulse; and in the full dose occasions active vomiting. The effects of an overdose are violent emesis, a burning sensation in the stomach, tormenting thirst, faintness, vertigo, dimness of vision, and alarming prostration. Four persons lost their lives at Bellevue Hospital, New York, in consequence of drinking largely of tincture of bloodroot, which they mistook for ardent spirit. (*Am. Journ. of Med. Sci.*, N. S., ii. 506.) Snuffed up the nostrils, bloodroot excites much irritation, attended with sneezing. Upon fungous surfaces it acts as an escharotic. It has been given in typhoid pneumonia, catarrh, pertussis, croup, phthisis pulmonalis, scarlatina, rheumatism, jaundice, dyspepsia, hydrothorax, and some other affections, either as an emetic, nauseant, or alterative; and its virtues are highly praised by many judicious practitioners. Dr. Mothershead, of Indianapolis, speaks in the strongest terms of its efficacy as an excitant to the liver, given in alterative doses. (See *Wood's Quart. Retrosp.*, ii. 80.)

The dose with a view to its emetic operation is from ten to twenty grains, given in powder or pill. The latter form is preferable, in consequence of the great irritation of throat produced by the powder when swallowed. For other purposes the dose is from one to five grains, repeated more or less frequently according to the effect desired. The medicine is sometimes given in infusion or decoction, in the proportion of half an ounce to the pint. The emetic dose of this preparation is from half a fluidounce to a fluidounce. The tincture is officinal. An infusion in vinegar has been employed advantageously, as a local application, in obstinate cutaneous affections; and Dr. R. G. Jennings has found it more efficient as a gargle in the sorethroat of scarlatina than any other that he has employed. (*Stethoscope*, ii. 182.) Dr. Stevens, of Ceres, New York, has found the powder useful as an errhine, in coryza, combined with cloves and camphor. (*N. Y. Journ. of Med.*, N. S., iv. 358.)

Gen. Ch. Calyx five-toothed. *Legume* falcated, leafy, varicose, girted by a wing, not gaping. *Seeds* solitary. *Willd.*

Pterocarpus santalinus. Willd. *Sp. Plant.* iii. 906; Woodv. *Med. Bot.* p. 430, t. 156. This is a large tree with alternate branches, and petiolate ternate leaves, each simple leaf being ovate, blunt, somewhat notched at the apex, entire, veined, smooth on the upper surface, and hoary beneath. The flowers are yellow, in axillary spikes, and have a papilionaceous corolla, of which the *vexillum* is obcordate, erect, somewhat reflexed at the sides, toothed and waved, the *alæ* spreading with their edges apparently toothed, and the *carina* oblong, short, and somewhat inflated. The tree is a native of India, attaining the highest perfection

in mountainous districts, and inhabiting especially the mountains of Coromandel and Ceylon. Its wood is the true officinal *red saunders*, though there is reason to believe that the product of other trees is sold by the same name.

The wood comes in roundish or angular billets, internally of a blood-red colour, externally brown from exposure, compact, heavy, and fibrous. It is kept in the shops in the state of small chips, raspings, or coarse powder.

Red saunders has little smell or taste. It imparts a red colour to alcohol, ether, and alkaline solutions, but not to water; and a test is thus afforded by which it may be distinguished from some other colouring woods. The alcoholic tincture produces a deep-violet precipitate with the sulphate of iron, a scarlet with the bichloride of mercury, and a violet with the soluble salts of lead. The colouring principle, which was separated by Pelletier, and called by him *santalin*, is of a resinous character, scarcely soluble in cold water, more so in boiling water, very soluble in alcohol, ether, acetic acid, and alkaline solutions, but slightly in the fixed and volatile oils, with the exception of those of lavender and rosemary, which readily dissolve it. It is precipitated when acids are added to the infusion of the wood prepared with an alkaline solution. Weyermann and Hœfferly have found it to be possessed of acid properties. The wood has no medical virtues, and is employed solely for the purpose of imparting colour.

Soaps, in the most extended signification of the term, embrace all those compounds which result from the reaction of salifiable bases with fats and oils. Fats and oils, as has been explained under the titles *Adeps* and *Olea*, consist of three principles, two solid, differing in fusibility, called *stearin* and *margarin*, and one liquid, called *olein*, of which there are two varieties. Stearin characterizes the fats which are firm and solid, as tallow; margarin, those that are soft like lard; and olein the oils. When the fats and oils undergo *saponification* by reaction with a salifiable base, these three principles are decomposed into oily acids peculiar to each, discovered by Chevreul, and called stearic, margaric, and oleic acids, which unite with the base to form the soap, and into a sweet principle not

saponifiable, called glycerin, which is set free. Hence it is inferred that stearin is a stearate, margarin a margarate, and olein an oleate of glycerin, and that the fats and oils are mixtures of these three oily salts. Hence, also, it is obvious that soaps are mixed stearates, margarates, and oleates of various bases. *Stearic acid* is a firm white solid, fusible at 167°, greasy to the touch, pulverizable, soluble in alcohol, very soluble in ether, but insoluble in water. In the impure state it is used as a substitute for wax, for making candles. *Margaric acid* has the appearance of fat, and is fusible at 140°. *Oleic acid* is an oily liquid, insoluble in water, soluble in alcohol and ether, lighter than water, crystallizable in needles a little below 32°, and having a slight smell and pungent taste. *Glycerin* will be described under a separate head. (See *Glycerina.*)

Soaps are divided into the soluble and insoluble. The soluble soaps are combinations of the oily acids with soda, potassa, and ammonia; the insoluble consist of the same acids united with earths and metallic oxides. It is the soluble soaps only that are detergent, and to which the name *soap* is generally applied. Several of the insoluble soaps are employed in pharmacy; as, for example, the soap of the protoxide of lead, or lead plaster, and the soap of lime, or lime liniment. (See *Emplastrum Plumbi* and *Linimentum Calcis.*)

The consistency of the fixed alkaline soaps depends partly on the nature of the oil or fat, and partly on the alkali present. Soaps are harder the more stearate and margarate they contain, and softer when the oleate predominates; and, as it respects the alkali present, they are harder when formed with soda, and softer when containing potassa. Hence it is that of pure soaps, considered as salts, stearate of soda is the hardest and least soluble, and oleate of potassa the softest and most soluble.

The officinal soaps, here described, embrace three varieties; namely, two soda soaps, one made with olive oil (Castile soap), the other with animal oil (common soap); and one potassa soap (soft soap). The soap of ammonia is noticed under another head. (See *Linimentum Ammoniæ.*)

Preparation. The following is an outline of the process for making soap. The oil or fat is boiled with a solution of caustic alkali, until the whole forms a thick mass, which can be drawn out into long clear threads. After the soap is completely formed, the next step is to separate it from the excess of alkali, the glycerin, and redundant water. This is effected by adding common salt, or a very strong alkaline lye, in either of which the soap is insoluble. The same end may be attained by boiling down the solution, until the excess of alkali forms a strong alkaline solution, which acts the same part in separating the soap as the addition of a similar solution. As soon as the soap is completely separated, it rises to the surface, and, when it has ceased to froth in boiling, is ladled out into wooden frames to congeal, after which it is cut into bars by means of a wire. The soap, as first separated, is called *grain soap.* It may be purified by dissolving it in an alkaline lye, and separating it by common salt. During this process the impurities subside, and the soap combines with more water; and hence it becomes weaker, although purer and whiter. If the grain soap be not purified it forms *marbled soap,* the coloured streaks arising principally from an insoluble soap of oxidized iron. Sometimes the marbled appearance is produced by adding to the soap, as soon as it is completely separated, a fresh portion of lye, and immediately afterwards a solution of sulphate of iron. The black oxide of iron is precipitated, and gives rise to dark-coloured streaks, which, by exposure to the air, become red, in consequence of the conversion of the black into the sesquioxide of iron.

The officinal *soap* (Sapo) of the U.S. and London Pharmacopœias is an olive oil soda soap, made on the same general plan as that just explained. It is the *Sapo Durus* of the Edinburgh and Dublin Colleges.

Common Soap (Sapo Vulgaris) is also a soda soap; but instead of olive it contains concrete animal oil. This soap corresponds with the white soap of Northern European countries and of the United States, and is formed usually from barilla and tallow. In Scotland it is manufactured from kelp and tallow. It was introduced into the list of the U. S. Pharmacopœia as the only proper soap for making opodeldoc. (See *Linimentum Saponis Camphoratum.*)

Soft Soap (Sapo Mollis) is prepared on the same general principles as hard soap; potash being employed as the alkali, and a fatty matter, rich in olëin, as the oil. The French soft soap is made with the seed oils, such as rape seed, hemp seed, &c.; the Scotch and Irish, with fish oil and some tallow; and our own with refuse fat and grease. A lye of wood-ashes is the form of potash usually employed. In forming this soap it is necessary that it should continue dissolved in the alkaline solution, instead of being separated from it. Hence soft soap is a soap of potassa, completely dissolved in the solution of its alkali, which is consequently present in excess. A soap of potassa is sometimes made with a view to its conversion into a soda soap. This conversion is effected by the addition of common salt, which, by double decomposition, generates a soap of soda, and chloride of potassium in solution. After this change is effected, the addition of a further portion of salt separates the soda soap formed.

Besides the officinal soaps of the United States and British Pharmacopœias, there are many other varieties, more or less used for medicinal or economical purposes. The officinal soap of the French Codex, called *amygdaline soap* (*almond oil soap*), is formed of caustic soda and almond oil, and is directed to be kept for two months exposed to the air, before being used. *Starkey's soap*, also officinal in the Codex, is prepared by uniting, by trituration, equal parts of carbonate of potassa, oil of turpentine, and Venice turpentine. *Beef's marrow soap* is a fine animal oil soap, also included in the French standard of pharmacy. *Windsor soap* is a scented soda soap, made of one part of olive oil and nine parts of tallow. *Eau de luce* (*aqua luciæ*) is a kind of liquid soap, formed by mixing a tincture of oil of amber and balsam of Gilead with water of ammonia. *Transparent soap* is prepared by saponifying kidney fat with soda free from foreign salts, drying the resulting soap, dissolving it in alcohol, filtering and evaporating the solution, and running it into moulds when sufficiently concentrated. The soap is yellow or yellowish-brown, and preserves its transparency after desiccation. *Palm soap* is prepared from soda and palm oil, to which tallow is added to increase its firmness. If it be wanted white, the palm oil must be bleached by sulphuric acid, by chlorine, or by exposure to the sun. This soap has a yellowish colour, and the agreeable odour of violets, derived from the oil. *Soap balls* are prepared by dissolving soap in a small quantity of water, and then forming it with starch into a mass of the proper consistence. *Common yellow soap* (*rosin soap*) derives its peculiarities from an admixture of rosin and a little palm oil with the tallow employed; the oil being added to improve its colour. Large quantities of lard oil (nearly pure olein) are manufactured into soap.

All the varieties of soap, except a few of the fancy sort and the olive oil soaps, are manufactured in the United States. The latter, which are chiefly used for medicinal purposes, are imported from France.

Properties. Soap, whatever may be its variety, has the same general properties. Its aspect and consistence are familiar to every one. Its smell is peculiar, and taste slightly alkaline. It is somewhat heavier than water, and therefore sinks in that liquid. Exposed to heat it quickly fuses, swells up, and is decomposed. It is soluble in water, and more readily in hot than in cold. Potassa soaps and those containing oleic acid are far more soluble than the soda soaps, especially those in which the stearates and margarates predominate. Acids, added to an aqueous solution of soap, combine with the alkali, and set free the

oily acids, which, being diffused through the water, give it a milky appearance. Its decomposition is also produced by metallic salts, which invariably give rise to insoluble soaps. Soap is soluble in cold, and abundantly in boiling alcohol. This solution constitutes the *tincture of soap*, and forms a very convenient test for discovering lime in natural waters. The efficacy of soap as a detergent depends upon its power of rendering grease and other soiling substances soluble in water, and, therefore, capable of being removed by washing. Various adulterations in soap are lime, gypsum, heavy spar, steatite, and pipe-clay, in which case it will not be entirely soluble in alcohol. According to Dr. Riegel, glue is an occasional adulteration in Spanish soap, discoverable also by its insolubility in alcohol. The same impurity is found in other soaps.

Olive oil soda soap (Sapo), otherwise called *Castile* or *Spanish soap*, is a hard soap, and is presented under two principal varieties, the white and the marbled. *White Castile soap*, when good, is of a pale grayish-white colour, incapable of giving an oily stain to paper, devoid of rancid odour or strong alkaline qualities, and entirely soluble both in water and alcohol. It should not feel greasy, nor grow moist, but, on the contrary, should become dry by exposure to the air, without exhibiting any saline efflorescence. This variety of soap contains about twenty-one per cent. of water. Sometimes it contains a larger proportion of water, with which the soap is made to combine by the manufacturer, with the fraudulent intention of increasing its weight. Soap, thus adulterated, is known by its unusual whiteness, and by its suffering a great loss of weight in a dry air. The proportion of water may be ascertained by introducing the soap into a saturated solution of chloride of sodium and boiling; when the soap, nearly free from water, concretes into a solid mass. *Marbled Castile soap* is harder, more alkaline, and more constant in its composition than the other variety. It contains about fourteen per cent. of water. Containing less water than the white Castile, it is a stronger and more economical soap; but at the same time less pure. The impurity arises from the veins of marbling, which consist of ferruginous matter, as already explained.

Animal oil soda soap (Sapo Vulgaris) is a hard soap, of a white colour, inclining to yellow. It is made from tallow and caustic soda. This soap possesses the same general properties as the olive oil soda soap.

Soft soap (Sapo Mollis), as made in this country, is semi-fluid, slippery, capable of being poured from one vessel to another, and of a dirty brownish-yellow colour. This soap always contains an excess of alkali, which causes it to act more powerfully as a detergent than hard soap. It also contains the glycerin of the fatty matters, which is always separated from hard soap. The London and Edinburgh Colleges direct it to be made from olive oil and potash; but Dr. Pereira states that he has not been able to meet with it in England. That which is made in France has a greenish colour and the consistence of soft ointment, and is composed of hemp seed oil and potash. It is called in the French Codex, *savon vert*. Sometimes it is manufactured from the dregs of olive oil.

Incompatibles. Soap is decomposed by all the acids, earths, and earthy and metallic salts. Acids combine with the alkali, and set free the oily acids of the soap; the earths unite with the oily acids and separate the alkali; while the earthy and metallic salts give rise, by double decomposition, to an insoluble soap of their base, and a saline combination between their acid and the alkali of the soap. Hard waters, in consequence of their containing salts of lime, decompose and curdle soap. They may be rendered soft and fit for washing, by adding sufficient carbonate of soda, or of potassa, to precipitate all the lime.

Composition. It has been already explained that soap consists of certain oily acids, united with an alkali. As olive oil is a compound of margarin and olëin, so the officinal "soap" is a mixed margarate and oleate of soda. The officinal

"common soap" is principally a stearate of soda, and "soft soap," as defined by the London and Edinburgh Colleges, is a mixed margarate and oleate of potassa. The most important soaps have the following composition in the hundred parts. *Marseilles white soap*,—soda 10·24, margaric acid 9·20, oleic acid 59·20, water 21·36. (*Braconnot.*) *Castile soap*, very dry,—soda, 9·0, oily acids 76·5, water 14·5. (*Ure.*) *Glasgow soft soap*,—potassa 9·0, oily acids 43·7, water 47·3. (*Ure.*) *French soft soap*,—potassa 9·5, oily acids 44, water 46·5. (*Thenard.*) Most soaps, it is perceived, contain a large proportion of water.

Medical Properties. Soap possesses the properties of a laxative, antacid, and antilithic. It is seldom given alone, but frequently in combination with rhubarb, the astringency of which it has a tendency to correct. Thus combined, it is frequently administered in dyspepsia, attended with constipation and torpor of the liver. As it is readily decomposed by the weakest acids, which combine with the alkali, it has proved useful in acidity of the stomach, and has been recommended as a remedy in the uric acid diathesis; but it possesses no power to dissolve calculi, as was once supposed. Externally, soap is a stimulating discutient, and as such has been used, by friction, in sprains and bruises. The late Dr. A. T. Thomson found much benefit to result from rubbing the tumid abdomen of children in mesenteric fever, morning and evening, with a strong lather of soap. In constipation of the bowels, particularly when arising from hardened feces in the rectum, a strong solution of soap, especially of soft soap, forms a useful enema. When the latter is used, two tablespoonfuls may be dissolved in a pint of warm water. In pharmacy, soap is frequently employed for the purpose of giving a proper consistence to pills; but care must be taken not to associate it with a substance which may be decomposed by it. It is also an ingredient in some liniments and plasters. In toxicology it is used as a counterpoison for the mineral acids, and should always be resorted to in poisoning by these agents without a moment's delay, and its use continued until magnesia, chalk, or the bicarbonate of soda or of potassa can be obtained. The mode of administration, in these cases, is to give a teacupful of a solution of soap, made by dissolving it in four times its weight of water, every three or four minutes, until the patient has taken as much as he can swallow. The dose of soap is from five grains to half a drachm, given in the form of pill.

SARSAPARILLA. *U. S., Dub.*

Sarsaparilla.

The root of Smilax officinalis and of other species of Smilax. *U. S.* Smilax officinalis. Jamaica Sarsaparilla. The root. *Dub.*

Off. Syn. SARSA. Smilax officinalis. The root. *Lond.;* SARZA. Root of Smilax officinalis, and probably other species. *Ed.*

Salsepareille, *Fr.;* Sarsaparille, *Germ.;* Salsapariglia, *Ital.;* Zarzaparrilla, *Span.*

Smilax. *Sex. Syst.* Dioecia Hexandria.—*Nat. Ord.* Smilaceæ.

Gen. Ch. MALE. *Calyx* six-leaved. *Corolla* none. FEMALE. *Calyx* six-leaved. *Corolla* none. *Styles* three. *Berry* three-celled. *Seeds* two. *Willd.*

Formerly, *Smilax Sarsaparilla* was admitted by most of the standard authorities as the source of this drug; but it is doubtful whether any of the sarsaparilla of the shops was ever obtained from that species. *S. Sarsaparilla* is a native of the United States; and the medicine has never, within our knowledge, been collected in this country. It is not among the eleven species of *Smilax* described by Humboldt, Bonpland, and Kunth, who indicate *S. officinalis*, *S. syphilitica*, and *S. Cumanensis*, especially the first, as the probable sources of the drug exported from Mexico and the Spanish Main. In the present state of our knowledge, it is impossible to decide with certainty from what species the several commercial varieties of the drug are respectively derived. This much is certain, that they do not proceed from the same plant. Of the many species belonging to this genus, few possess any medicinal power; and Hancock states that of the six or eight which he found growing in the woods of Guiana, only one presented in any degree the sensible properties of the genuine sarsaparilla, the rest being insipid and inert. The root (rhizoma) of *Smilax China*, a native of China and Japan, has been employed under the name of *China root* for similar purposes with the officinal sarsaparilla. As it occurs in commerce, it is in pieces from three to eight inches long and an inch or two thick, usually somewhat flattened, more or less knotty, often branched, of a brownish or grayish-brown colour externally, whitish or of a light flesh-colour internally, without odour, and of a taste flat at first, but afterwards very slightly bitterish and somewhat acrid, like that of sarsaparilla. The root of *Smilax aspera* is said to be employed in the South of Europe as a substitute for sarsaparilla; but it has little reputation. The East India sarsaparilla, which was at one time referred to this species of Smilax, is now known to be the product of *Hemidesmus Indicus*. (See *Hemidesmus*.) We shall briefly describe S. Sarsaparilla, on account of its former officinal rank, and afterwards such other species as are believed to yield any portion of the drug. All of these species are climbing or trailing plants, with prickly stems; a character expressed in the name of the medicine, which is derived from two Spanish words (*zarza* and *parilla*), signifying a small thorny vine.

Smilax Sarsaparilla. Willd. *Sp. Plant.* iv. 776; Woodv. *Med. Bot.* p. 161, t. 62. The stem of this plant is long, slender, shrubby, angular, and beset with prickles. The leaves are unarmed, ovate-lanceolate with about five nerves, somewhat glaucous beneath, and supported alternately upon footstalks, at the bases of which are long tendrils. The flowers usually stand three or four together, upon a common peduncle, which is longer than the leafstalk. This species is indigenous, growing in swamps and hedges in the Middle and Southern States.

S. officinalis. Humb. and Bonpl. *Plant. Æquinoct.* i. 271. In this species the stem is twining, angular, smooth, and prickly; the young shoots are unarmed; the leaves ovate-oblong, acute, cordiform, five or seven-nerved, coriaceous, smooth, twelve inches long and four or five broad, with footstalks an inch long, smooth, and furnished with tendrils. The young leaves are lanceolate-oblong, acuminate, and three-nerved. According to Humboldt, the plant abounds on the river Magdalena, in New Granada, where it is called *zarzaparilla* by the natives. Large quantities of the root are sent down the river to Mompox and Carthagena.

S. Syphilitica. Willd. *Sp. Plant.* iv. 780. The stem is round and smooth; armed at the joints with from two to four thick, straight prickles; and furnished with oblong-lanceolate, acuminate, three-nerved, coriaceous, shining leaves, which are a foot in length, and terminate by a long point. The plant was seen by Humboldt and Bonpland in New Granada, upon the banks of the river Cassiquiare, and by Martius in Brazil, at Yupura and near the Rio Negro. It has been supposed to yield the Brazilian sarsaparilla.

S. Papyracea. Poiret, *Encyc. Méth.* iv. 467. This is an under-shrub with a compressed stem, angular below, and furnished with spines at the angles. Its leaves are elliptical, acuminate, and three-nerved. It inhabits Cayenne and Brazil, chiefly upon the banks of the Amazon and its tributaries, and is thought to yield the variety of sarsaparilla denominated Brazilian. (*Am. Journ. of Pharm.*, xv. 277.) A particular description of a specimen of Smilax, supposed to belong to this species, is given by Professor Bentley in the *London Pharm. Journ. and Trans.* (x. 470). It was obtained from Guatemala, and was the source of a variety of commercial sarsaparilla, recently introduced into the market, which Professor Bentley proposes to name Guatemala sarsaparilla.

S. medica. Schlechtendahl, *in Linnæa*, vi. 47; Carson, *Illust. of Med. Bot.* ii. 51, pl. 95. This species has an angular stem, armed with straight prickles at the joints, and a few hooked ones in the intervals. The leaves are smooth, bright-green on both sides, shortly acuminate, five-nerved, with the veins prominent beneath. They vary much in form, the lower being cordate, auriculate-hastate; the upper cordate-ovate. In the old leaves, the petiole and midrib are armed with straight subulate prickles. The inflorescence is an umbel of from eight to twelve flowers, with a smooth axillary peduncle, and pedicels about three lines long. Schiede found this plant on the eastern declivity of the Mexican Andes, where the root is collected to be taken to Vera Cruz.

The medicinal species of Smilax grow in Mexico, Guatemala, and the warm latitudes of South America. The roots are very long and slender, and originate in great numbers from a common head or rhizoma, from which the stems of the plant rise. The whole root with the rhizoma is usually dug up, and as brought into market exhibits not unfrequently portions of the stems attached, sometimes several inches in length. The sarsaparilla of commerce comes from different sources, and is divided into varieties according to the place of collection or shipment.

Honduras Sarsaparilla is the variety most used in this country. It is brought from the bay of *Honduras*, and comes in bundles two or three feet long, composed of several roots folded lengthwise, and secured in a compact form by a few circular turns. These are packed in bales imperfectly covered with skins, each bale containing one hundred pounds or more. The roots are usually connected at one extremity in large numbers in a common head, to which portions of the stems are also attached. In some bundles are many small fibres either lying loose, or still adhering to the roots. The colour of the roots externally is a dirty grayish or reddish-brown; and the cortical portion beneath the epidermis often appears amylaceous when broken.

The *Jamaica* or *red sarsaparilla* of foreign writers is little known by that name in the United States. The island of Jamaica is merely its channel of exportation to Europe, and it is probably derived originally from Central America. It does not materially differ in properties from Honduras sarsaparilla; its chief peculiarity being the reddish colour of the epidermis, which is also sometimes found in that variety. It is said also to yield a larger proportion of extract, and to contain less starch. As found in commerce, it is in bundles twelve or eighteen inches long, by four or five in thickness, consisting of long slender roots folded up, with numerous radical fibres attached.

Considerable quantities of the drug are imported from the Mexican ports of Vera Cruz and Tampico. The *Vera Cruz sarsaparilla* comes in large, rather loose bales, weighing about two hundred pounds, bound with cords or leather thongs, and usually containing the roots folded upon themselves, and separately packed. These, as in the Honduras sarsaparilla, consist of a head or caudex with numerous long radicles, which, however, are somewhat smaller than in that variety, and have a thinner bark. They are often also much soiled with earth. This variety is not highly esteemed; but from the acrid taste which it possesses,

it is probably not inferior in real virtues to the other kinds. It is probably derived from the Smilax medica.

Another variety is the *Caracas sarsaparilla*, brought in large quantities from La Guayra. It is in oblong packages, of about one hundred pounds, surrounded with broad strips of hide, which are connected laterally with thongs of the same material, and leave much of the root exposed. The roots, as in the last variety, are separately packed, but more closely and with greater care. The radicles are often very amylaceous internally, in this respect resembling the following.

The *Brazilian*, or, as it is sometimes called in Europe, the *Lisbon sarsaparilla*, is less used in the United States than in Europe, where it has commanded a higher price. Within a few years, however, it has been imported in considerable quantities. It comes from the ports of Para and Maranham, in cylindrical bundles of from three to five feet in length, by about a foot in thickness, bound about by close circular turns of a very flexible stem, and consisting of unfolded roots, destitute of caudex (rhizoma) and stems, and having few radical fibres. It is the variety of which Hancock speaks as celebrated throughout South America by the name of *sarsa of the Rio Negro*, and is considered as the most valuable variety of the drug. It is distinguished by the amylaceous character of its interior structure, and has considerable acrimony. It was said by Martius to be derived from Smilax syphilitica; but Dr. Hancock considers that portion of it which comes from the Rio Negro, and is shipped at Para, as the product of an undescribed species, certainly not S. syphilitca. According to Richard, it has been ascertained to be the product of the S. papyracea of Poiret. (See *Am. Journ. of Pharm.*, xv. 277.)

The variety described by Professor Bentley under the name of *Guatemala sarsaparilla* was collected in the province of Sacatepequcs, about ninety miles from the sea. It is in cylindrical bundles about two feet eight inches long by four inches in diameter, composed of separate roots, arranged in parallel order, without rootstalk, and bound together by a few turns of the flexible stem of a monocotyledonous plant. The bundles resemble the Brazilian in arrangement, but are much less compact. It is amylaceous, has considerable acrimony, and is probably one of the most efficient varieties. Professor Bentley ascribes it to S papyracea. For a particular description of the root, the reader is referred to the *Pharm. Journ. and Trans.* (xii. 472).

Much sarsaparilla has been imported into England from Lima, Valparaiso, and other places on the Pacific coast of South America. It is described by Pereira as bearing a close resemblance to Jamaica sarsaparilla, but yielding a smaller proportion of extract. It is in bundles of about three feet long and nine inches thick, consisting of the roots folded with their heads or rhizoma attached. The epidermis is brown or grayish-brown. Sometimes roots of a light clay colour are found in the bundles.

Properties. The dried sarsaparilla roots are several feet in length, about the thickness of a goose-quill, cylindrical, more or less wrinkled longitudinally, flexible, and composed of a thick exterior cortical portion, covered with a thin easily separable epidermis, of an inner layer of ligneous fibre, and of a central pith. The epidermis is of various colours, generally ash-coloured, grayish-brown, or reddish-brown, and sometimes very dark. The cortical portion is in some specimens whitish, in others brown, and not unfrequently of a pink or rosy hue. It is occasionally white, brittle, and almost powdery like starch. The woody part is usually very thin, and composed of longitudinal fibres, which allow the root to be split with facility through its whole length. The central medulla often abounds in starch.

Sarsaparilla in its ordinary state is nearly or quite inodorous, but in decoction acquires a decided and peculiar smell. To the taste it is mucilaginous and

very slightly bitter, and, when chewed for some time, produces a disagreeable acrid impression, which remains long in the mouth and fauces. The root is efficient in proportion as it possesses this acrimony, which is said by some authors to be confined to the cortical portion, while the ligneous fibre and medullary matter are insipid and inert. Hancock avers that all parts are equally acrid and efficacious. The truth is probably between the two extremes; and, as in most medicinal roots, it must be admitted that the bark is more powerful than the interior portions, while these are not wholly inactive. The virtues of the root are communicated to water cold or hot, but are impaired by long boiling. (See *Decoctum Sarsaparillæ.*) They are extracted also by diluted alcohol. According to Hancock, the whole of the active principle is not extracted by water. He observes in his paper upon sarsaparilla, published in the *London Medico-Botanical Transactions*, when speaking of the sarsaparilla from Para and the Rio Negro, "after exhausting half a pound of this sort by two digestions, boiling, and pressure, I added to the dregs half a pint of proof spirit, and digested this with a gentle heat for a few hours in a close vessel, then affusing hot water to the amount of that taken off from the first boiling, and pressing again, I procured by the last operation about four pints of an infusion which possessed the acrid properties of the sarsa in a much higher degree even than that obtained by the first decoction with simple water." It appears that in South America it is the custom to prepare sarsaparilla by digestion in wine or spirit, or by infusion in water with additions which may produce the vinous fermentation, and thus add alcohol to the menstruum. The same result, as to the superior efficacy of alcohol as a solvent of the acrid principle of sarsaparilla, has been obtained by the French experimentalists. (Soubeiran, *Journ. de Pharm.*, xvi. 38.)

According to M. Thubeuf, sarsaparilla contains, 1. a peculiar crystalline substance, which is probably the active principle of the root, 2. a colouring substance, 3. resin, 4. starch, 5. lignin, 6. a thick, aromatic, fixed oil, 7. a waxy substance, and 8. chloride of potassium and nitrate of potassa. It is said also to contain a minute proportion of volatile oil, and Batka found gum, bassorin, albumen, gluten and gliadine, lactic and acetic acids, and various salts. The proportion of starch is large. Chatin found iodine in Honduras sarsaparilla; but Dr. Winckler, not having succeeded in detecting this principle in any one root, thinks it probable that the specimen examined by Chatin had been exposed to sea-water. (*Pharm. Cent. Blatt*, May 7, 1852.)

Sarsaparillin. (*Smilacin. Pariglin. Salseparine. Parillinic acid.*) The crystalline principle in which the virtues of sarsaparilla reside should be called *sarsaparillin.* It was first discovered by Dr. Palotta, who described it in 1824 under the name of *pariglin.* Subsequently, M. Folchi supposed that he had found another principle which he called *smilacin.* In 1831, M. Thubeuf announced the discovery of a new substance in sarsaparilla which he named *salseparine*, from the French name of the root. Finally, Batka, a German chemist, towards the end of 1833, published an account of a principle which he had discovered in the root, and which, under the impression that it possessed acid properties, he called *parillinic acid.* M. Poggiale, however, has shown that these substances are identical, though procured by different processes. The following is the process of M. Thubeuf. The root is treated with hot alcohol till deprived of taste. The tincture is submitted to distillation, and seven-eighths of the alcohol drawn off. The remainder is treated with animal charcoal, and filtered at the end of twenty-four or forty-eight hours. The sarsaparillin is deposited in the form of a granular powder. This is dissolved in a fresh portion of alcohol and crystallized. The alcoholic mother liquors may be deprived of that portion of the principle which they retain by evaporating to dryness, dissolving the product in water, filtering, again evaporating to dryness, redissolving in alcohol,

and crystallizing. *Sarsaparillin* is white, inodorous, almost tasteless in the solid state, but of a bitter, acrid, nauseous taste, when dissolved in alcohol or water. It is very slightly soluble in cold water, but more readily in boiling water, which deposits it on cooling. It is very soluble in alcohol, especially at a boiling temperature. Ether and the volatile oils also dissolve it. Its aqueous solution has the property of frothing very much by agitation. M. Beral states that he has procured it pure by distilling, by means of a salt-water bath, a tincture of sarsaparilla prepared with very dilute alcohol. In that case it must be volatile, and we can understand why sarsaparilla suffers in decoction. (*Am. Journ. of Pharm.*, xii. 245, from *Journ. de Chim. Méd.*) The solutions of sarsaparillin are without acid or alkaline reaction. Batka erred in considering it an acid. M. Poggiale found it both in the cortical and medullary part of the root, but most largely in the former. Pallotta gave it internally in doses varying from two to thirteen grains, and found it to produce nausea, and to diminish the force of the circulation. It is probably the principle upon which sarsaparilla depends chiefly, if not exclusively, for its remedial powers. (*Journ. de Pharm.*, xx. 553 and 679.)

The sarsaparilla of the shops is apt to be nearly if not quite inert, either from age, or from having been obtained from inferior species of Smilax. This inequality of the medicine, with the improper modes of preparing it long in vogue, has probably contributed to its variable reputation. The only criterion of good sarsaparilla to be relied on is the taste. If it leave a decidedly acrid impression in the mouth after having been chewed for a short time, it may be considered efficient; if otherwise, it is probably inert.

Medical Properties and Uses. Few medicines have undergone greater changes of reputation. About the middle of the sixteenth century it was introduced into Europe as a remedy for the venereal complaint, in which it had been found very useful in the recent Spanish settlements in the West Indies. After a time it fell into disrepute, and was little employed till about a century ago, when it was again brought into notice by Sir William Fordyce and others, as a useful adjuvant and corrigent of mercury in lues venerea. Since that period very different opinions have been entertained of its efficacy. Some, among whom was Dr. Cullen, considered it wholly inert; others, on the contrary, have had the most unbounded confidence in its powers. The probable cause of much of this discrepancy has been already mentioned. Experience, both among regular practitioners and empirics, would seem to have placed its efficacy beyond reasonable doubt. Its most extensive and useful application is to the treatment of secondary syphilis and syphiloid diseases, and that shattered state of the system which sometimes follows the imprudent use of mercury in these affections. It is also employed, though with less obvious benefit, in chronic rheumatism, scrofulous affections, certain cutaneous diseases, and other depraved conditions of health. Its mode of action is less evident than its ultimate effects. It is said to increase the perspiration and urine; but, allowing it to possess this power, the amount of effect is too trifling to explain its remedial influence; and the diaphoretic and diuretic action which it appears to evince may perhaps be as justly ascribed to the medicines with which it is generally associated, or the liquid in which it is exhibited. In this ignorance of its precise *modus operandi* we call it an alterative, as those medicines are named which change existing morbid actions, without obvious influence over any of the functions.

Sarsaparilla may be given in powder, in the dose of half a drachm three or four times a day. The medicine, however, is more conveniently administered in the form of infusion, decoction, syrup, or extract. (*See the several officinal preparations* in Part II.) A beer, made by fermenting an infusion of the drug

with molasses, is said to be a popular remedy in South America.* The smoke of sarsaparilla has been highly recommended in asthma. (*Journ. de Pharm. et de Chim.*, xviii. 221.)

Sassafras Pith.

The pith of the stems of Sassafras officinale. *U. S.*

SASSAFRAS RADICIS CORTEX. *U. S.*

Bark of Sassafras Root.

The bark of the root of Sassafras officinale. *U. S.*

Off. Syn. SASSAFRAS. Sassafras officinale. The root. *Lond., Ed.* SASSAFRAS ROOT. Sassafras officinale. The root. *Dub.*

Sassafras, *Fr., Germ.;* Sassafras, Sassafrasso, *Ital.;* Sasafras, *Span.*

In the new distribution of the species composing the genus Laurus of Linnæus, the sassafras tree has been made the type of a distinct genus, denominated *Sassafras*, which has been admitted into the last edition of our Pharmacopœia.

Sassafras. *Sex. Syst.* Enneandria Monogynia. — *Nat. Ord.* Lauraceæ.

Gen. Ch. Dicœcious. *Calyx* six-parted, membranous; segments equal, permanent at the base. Males. *Fertile stamens* nine, in three rows, the three inner with double stalked distinct glands at the base. *Anthers* linear, four-celled, all looking inwards. Females, with as many sterile stamens as the males or fewer; the inner often confluent. *Fruit* succulent, placed on the thick fleshy apex of the peduncle, and seated in the torn unchanged calyx. (*Lindley.*)

Sassafras officinale. Nees, *Laurin.* 488.—*Laurus Sassafras.* Willd. *Sp. Plant.* ii. 485; Bigelow, *Am. Med. Bot.* ii. 142; Michaux, *N. Am. Sylv.* ii. 144. This is an indigenous tree of middling size, rising in favourable situations from thirty to fifty feet in height, with a trunk about a foot in diameter. In the Southern States it is sometimes larger, and in the northern parts of New England is little more than a shrub. The bark which covers the stem and large branches is rough, deeply furrowed, and grayish; that of the extreme branches or twigs is smooth and beautifully green. The leaves, which are alternate, petiolate, and downy when young, vary much in their form and size even upon the same tree. Some are oval and entire, others have a lobe on one side; but the greater number are three lobed. Their mean length is four or five inches. The flowers, which are frequently dicœcious, and appear before the leaves, are small, of a pale greenish-yellow colour, and disposed in racemes which spring from the branches below the leaves, and have linear bractes at their base. The corolla is divided into six oblong segments. The male flowers have nine stamens; the hermaphrodite,

* The following is a formula recommended by Hancock. "Take of Rio Negro sarsa, bruised, 2lb.; bark of guaiac, powdered, 8oz.; raspings of guaiac wood, anise seeds, and liquorice root, each 4oz.; mezereon, *bark of the root*, 2oz.; treacle [molasses] 2lb.; and a dozen bruised cloves; pour upon these ingredients about four gallons of boiling water, and shake the vessel thrice a day. When fermentation has well begun, it is fit for use, and may be taken in the dose of a small tumblerful twice or thrice a day." This formula is worthy of attention; but the bark of guaiacum, which is not kept in the shops, might be omitted, or replaced by the wood.

which are on a different plant, have only six, with a simple style. The fruit is an oval drupe, about as large as a pea, of a deep-blue colour when ripe, and supported on a red pedicel, which enlarges at the extremity into a cup for its reception.

The sassafras is common throughout the United States, and extends into Mexico. It is said also to grow in Brazil and Cochin China; but the plants observed in these places are probably not of the same species. In this country the sassafras is found both in woods and open places, and is apt to spring up in the neighbourhood of cultivation, and in neglected or abandoned fields. In Pennsylvania and New York, it blooms in the beginning of May; but much earlier at the South. The fresh flowers have a slightly fragrant odour, and almost all parts of the plant are more or less aromatic. The root is directed by the British Pharmacopœias; the bark of the root, and the pith of the twigs or extreme branches, by that of the United States. The root is exported, and is the part chiefly used in British pharmacy. It consists of a brownish-white wood, covered with a spongy bark divisible into layers. The latter portion is by far the most active, and is usually kept separate in our shops.

1. *Sassafras Pith.* This is in slender cylindrical pieces, very light and spongy, with a mucilaginous taste, and in a slight degree the characteristic flavour of the sassafras. It abounds in a gummy matter, which it readily imparts to water, forming a limpid mucilage, which, though ropy and viscid, has much less tenacity than that of gum Arabic, and will not answer as a substitute in the suspension of insoluble substances. It differs also from solutions of ordinary gum, in remaining limpid when added to alcohol. This mucilage is much employed as a mild and soothing application in inflammation of the eyes; and forms an agreeable and useful drink in dysenteric, catarrhal, and nephritic diseases. It may be prepared by adding a drachm of the pith to a pint of boiling water.

2. *Bark of Sassafras Root.* As found in the shops, this is usually in small irregular fragments, sometimes invested with a brownish epidermis, sometimes partially or wholly freed from it, of a reddish or rusty cinnamon hue, very brittle, and presenting when freshly broken a lighter colour than that of the exposed surfaces. Its odour is highly fragrant, its taste sweetish and gratefully aromatic. These properties are extracted by water and alcohol. They reside in a volatile oil, which is obtained by distillation with water. (See *Oleum Sassafras.*) According to Dr. Reinsch, the bark contains a heavy and light volatile oil, camphorous matter, fatty matter, resin, wax, a peculiar principle resembling tannic acid called *sassafrid*, tannic acid, gum, albumen, starch, red colouring matter, lignin, and salts. (See *Am. Journ. of Pharm.*, xviii. 159.)

Medical Properties and Uses. The bark of sassafras root is stimulant, and perhaps diaphoretic; though its possession of any peculiar tendency to the skin, independently of its mere excitant property, is quite doubtful. It is used almost exclusively as an adjuvant to other more efficient medicines, the flavour of which it improves, while it renders them more cordial to the stomach. The complaints for which it has been particularly recommended are chronic rheumatism, cutaneous eruptions, and scorbutic and syphiloid affections. As a remedy in lues venerea, in which it formerly had a high reputation, it is now universally considered as in itself wholly inefficient. It is most conveniently administered in the form of infusion. The oil may also be given.

SCAMMONIUM. *U. S., Lond., Ed., Dub.*

Scammony.

The concrete juice of the root of Convolvulus Scammonia. *U. S.* The gum-resin emitted from the root cut off. *Lond.* Gummy-resinous exudation from incisions into the root. *Ed., Dub.*

Scammonée, *Fr.;* Scammonium, *Germ.;* Scamonea, *Ital.;* Escamonea, *Span.*

CONVOLVULUS. *Sex. Syst.* Pentandria Monogynia. — *Nat. Ord.* Convolvulaceæ.

Gen. Ch. Corolla campanulate. *Style* one. *Stigmas* two, linear-cylindrical, often revolute. *Ovary* two-celled, four-seeded. *Capsule* two-celled. (*Lindley.*)

Convolvolus Scammonia. Willd. *Sp. Plant.* i. 845; Woodv. *Med. Bot.* p. 243, t. 86; Carson, *Illust. of Med. Bot.* ii. 14, pl. 62. This species of Convolvulus has a perennial, tapering root, from three to four feet long, from nine to twelve inches in circumference, branching towards its lower extremity, covered with a light-gray bark, and containing a milky juice. The stems are numerous, slender, and twining, extending sometimes fifteen or twenty feet upon the ground, or on neighbouring plants, and furnished with smooth, bright-green, arrow-shaped leaves, which stand alternately upon long footstalks. The flowers are placed in pairs, or three together upon the peduncles, which are round, axillary, solitary, and of nearly twice the length of the leaf.

The plant is a native of Syria, Anatolia, and certain islands of the Archipelago. No part is medicinal except the root, which, when dried, was found by Dr. Russel to be a mild cathartic. Scammony is the concrete juice of the fresh root, and is collected, according to Russel, in the following manner. In the month of June, the earth is cleared away from about the root, the top of which is cut off obliquely about two inches from the origin of the stems. The milky juice which exudes is collected in shells, or other convenient receptacle, placed at the most depending part of the cut surface. A few drachms only are collected from each root. The juice from several plants is put into any convenient vessel, and concretes by time. In this state it constitutes genuine scammony, but is very seldom exported. It is generally prepared for the market by admixture, while it is yet soft, with the expressed juice of the stalks and leaves, with wheat flour, ashes, fine sand, &c.; and it has been supposed that scammony sometimes consists wholly or in great part of the expressed juice of the root, evaporated to dryness by exposure to the sun, or by artificial heat. The drug is exported chiefly from Smyrna, though small quantities are said to be sent out of the country at Alexandretta, the seaport of Aleppo. Dr. Pereira was informed by a merchant who had resided in Smyrna, that it is brought upon camels in a soft state into that city, and afterwards adulterated by a set of individuals called scammony makers. The adulteration appears to be conducted in conformity with a certain understood scale, more or less foreign matter being added according to the price. The materials employed are chiefly chalk and some kind of flour or meal. Very little comparatively is exported perfectly pure. We obtain scammony either directly from Smyrna, or indirectly through some of the Mediterranean ports.*

* An interesting account of the collection and preparation of scammony in Anatolia, in the vicinity of Smyrna, has been communicated by Mr. S. H. Maltass to the *London Pharmaceutical Journ. and Trans.* (xiii. 264). The juice is collected in the same manner as described by Russel in reference to Syria. The product, however, of each plant is somewhat less. In some districts, according to Maltass, ten plants produce only a drachm of scammony; in others the average from each root is a drachm; and in a good soil a plant four years old will yield two drachms. The juice received in the shells is mixed with another portion scraped from the cut surface of the root; and this mixture is the pure or *lachryma scammony.* Only a small quantity of this is taken to Smyrna; the greater part being adulterated

The name of *Aleppo scammony* was formerly given to the better kinds of the drug, and of *Smyrna scammony* to those of inferior quality; the distinction having probably originated in some difference in the character of the scammony obtained at these two places. But no such difference now exists; as scammony is brought from Smyrna of every degree of purity. It has been customary in this country to designate the genuine drug of whatever quality as Aleppo scammony; while the name of Smyrna scammony has been given to a spurious article manufactured in the South of France, and to other factitious substitutes. It is quite time that these terms should be altogether abandoned. We shall treat of the drug under the heads of genuine and factitious scammony.

Genuine Scammony. This is sent into commerce in drums or boxes, and is either in irregular lumps, in large solid masses of the shape of the containing vessel into which it appears to have been introduced while yet soft, or in circular, flattish or plano-convex cakes. It seldom reaches us in an unmixed state. Formerly small portions of pure scammony were occasionally to be met with in Europe, contained in the shells in which the juice was collected and dried. This variety, denominated *scammony in shells*, is now scarcely to be found. The pure drug, as at present known in the shops of London, and occasionally brought to this country, is called *virgin scammony*. It is in irregular pieces, often covered with a whitish-gray powder, friable and easily broken into small fragments between the fingers, with a shining grayish-green fracture soon passing into greenish-black, and exhibiting under the microscope minute air-cells, and numerous gray semi-transparent splinters.* It is easily pulverized, affording a pale ash-gray powder. When rubbed with water it readily forms a milky emulsion. It has a rather strong, peculiar odour, which has been compared to that of old cheese. The taste is feeble at first, and afterwards somewhat acrid, but without bitterness. It gives no evidence, when the requisite tests are applied, of the presence of starch or carbonate of lime, leaves but a slight residue when burned, and yields about 80 per cent. of its weight to ether.

The form of scammony chiefly found in our markets is that in circular cakes. These are sometimes flattish on both sides, but generally somewhat convex on one side and flat on the other, as if dried in a saucer, or other shallow vessel. They are from four to six inches in diameter, and from half an inch to an inch and a half, or even two inches thick in the centre. As found in the retail shops, they are often in fragments. They are hard and heavy, with a faintly shining roughish fracture; and when broken exhibit in general a structure very finely

by the peasants before it reaches the market. Sometimes the juice is worked up with a decoction of the roots, in which case it is black, heavier than the preceding, and not so easily broken. Sometimes they add a calcareous earth, in a proportion varying from 10 to 150 per cent. The kind thus prepared is usually kept for some time in Smyrna, and is apt to ferment, so as to become porous and lose its gloss. It is in irregular lumps, and is the kind usually sold in London as *lachryma scammony*. Another kind sold in London in rough lumps, and probably under the same name, is prepared in the interior of the country by mixing the juice with wheat starch, ashes, earthy matters, gum arabic or tragacanth, and sometimes wax, yolk of egg, pounded scammony roots and leaves, flour, or resin. A kind much used in Great Britain is prepared by the Jews in Smyrna, and is in the form of cakes as described in the text. It is of two qualities. The *first quality* is prepared by mixing *skilip* (which is an inferior kind of scammony prepared at Anjora, and consists of 30 to 40 per cent. of juice and 60 to 70 of starch) with 60 per cent. of inferior scammony from the neighbourhood of Smyrna; the *second quality* by mixing *skilip* with about 30 per cent. of the latter kind, and adding about 10 per cent. of gum arabic and black-lead. The *first quality* contains usually about 50 per cent. of resin, the *second* about 30 per cent. For an account of several specimens of scammony sent by Mr. Maltass from Smyrna, see a paper by Mr. Daniel Hanbury in the *Pharm. Journ. and Trans.*, xiii. 268.—*Note to the tenth edition.*

* According to Maltass, the purest scammony has a reddish-black fracture, unless it has been mixed with water in its preparation, in which case it is black and very glossy. (*Pharm. Journ. and Trans.*, xiii. 266.)

porous, sometimes almost compact, and in a very few instances cavernous. Their colour externally is a dark ash or dark olive, or slate colour approaching to black; internally somewhat lighter and grayish, with an occasional tinge of green or yellow, but deepening by exposure. The small fragments are sometimes slightly translucent at the edges. The mass, though hard, is pulverizable without great difficulty, and affords a light-gray powder. It imparts to water with which it is triturated a greenish milky appearance. The smell is rather disagreeable, and similar to that of the pure drug. The taste, very slight at first, becomes feebly bitterish and acrid. This kind of scammony is never quite pure, and much of it is considerably adulterated. In some of the cakes carbonate of lime is the chief impurity; in others the adulterating substance is probably meal, as evidences of the presence of starch and lignin are afforded; and in others again both these substances are found. Christison discovered in the chalky specimens a proportion of carbonate of lime varying from 15 to 38 per cent.; in the amylaceous, from 13 to 42 per cent. of impurity. It was probably to the flat, dark-coloured, compact, difficultly pulverizable, and more impure cakes that the name of *Smyrna scammony* was formerly given. These have been erroneously ascribed by some to the *Periploca Secamone*, a plant growing in Egypt.*

Scammony is ranked among the gum-resins. It is partially dissolved by water, much more largely by alcohol and ether, and almost entirely, when pure, by boiling diluted alcohol. Its active ingredient is resin, which constitutes from

* Dr. Pereira, in his work on Materia Medica, describes the varieties of scammony as they exist in the London market. As these have interest for the druggist, we introduce a notice of them.

1. *Virgin Scammony. Pure Scammony. Lachryma Scammony.* The description of this corresponds with that of pure scammony given in the text. In addition, the following particulars may be mentioned. The whitish powder often found upon the surface effervesces with muriatic acid, and consists of chalk, in which the lumps have probably been rolled. The sp. gr. of the masses is 1·210. In the same pieces it sometimes happens that certain portions are shining and black, while others are dull-grayish. Virgin scammony readily takes fire, and burns with a yellowish flame. This variety is now much more abundant in the shops of London than formerly.

2. *Scammony of second quality.* This is called *seconds* in commerce. It is in two forms. 1. In *irregular pieces.* This, in external appearance, brittleness, odour, and taste, resembles virgin scammony; but is distinguished by its greater sp. gr., which is 1·463, by its dull, very slightly shining fracture, and its grayish colour. The freshly broken surface effervesces with muriatic acid, but the cold decoction does not give a blue colour with iodine. It therefore contains chalk, but not fecula. 2. In *large regular masses.* This has the form of the drum or box in which it was imported, and into which it was probably introduced while soft. It has a dull grayish fracture, and the sp. gr. 1·359. It exhibits, with the appropriate tests, evidence of the presence both of chalk and fecula. It is sometimes found of a soft or cheesy consistence.

3. *Scammony of third quality.* This is called *thirds* in commerce. It is in circular flat cakes, about five inches in diameter and one inch thick. The cakes are dense, heavy, and more difficult to break than the preceding varieties. The fracture is sometimes resinous and shining, sometimes dull, and exhibits air cavities, and numerous white specks, which consist of chalk. The colour is grayish or grayish-black. The sp. gr. varies from 1·276 to 1·543. Both chalk and flour are detected by tests. In five different cakes, the quantity of chalk employed in the adulteration was stated by the importer to be, in 100 parts of the cakes respectively, 13·07, 23·1, 25·0, 31·05, and 37·54, numbers which correspond very closely, in the two extremes, with the results obtained by Christison. This is the variety of scammony referred to in the text as the one chiefly used in the United States.

A valuable paper by Dr. Carson, on the varieties of scammony imported into this country, was published in the *Am. Journ. of Pharm.* (xx. i.), to which the reader is referred. Besides the kinds described in the text, namely the virgin scammony, and those which are adulterated with chalk or meal or both, Dr. Carson describes two, under the names of *gummy* and *black gummy* scammony, in which the chief adulteration appears to be tragacanth, or some analogous substance, which is associated in the dark variety with bone-black. They afforded from 6 to 13 per cent. of resin. They are in circular cakes, hard, compact, of difficult pulverization, and viscid when moistened.—*Note to the eighth edition.*

80 to 90 per cent. of pure dry scammony. The gum-resin has been analyzed by various chemists, but the results are somewhat uncertain; as the character of the specimens examined is insufficiently determined by the terms Aleppo and Smyrna scammony, employed to designate them. Thus, Bouillon-Lagrange and Vogel obtained, from 100 parts of Aleppo scammony, 60 of resin, 3 of gum, 2 of extractive, and 35 of insoluble matter; from the same quantity of Smyrna scammony, 29 parts of resin, 8 of gum, 5 of extractive, and 58 of vegetable remains and earthy substances. It is obvious that both the specimens upon which they operated were very impure. Marquart found in pure scammony (*scammony in shells*) 81·25 per cent. of resin, 3·00 of gum with salts, 0·75 of wax, 4·50 of extractive, 1·75 of starchy envelopes, bassorin, and gluten, 1·50 of albumen and lignin, 3·75 of ferruginous alumina, chalk, and carbonate of magnesia, and 3 50 of sand. Christison found different specimens of pure scammony to contain, in 100 parts, from 77 to 83 parts of resin, from 6 to 8 of gum, from 3·2 to 5 of lignin and sand, and from 7·2 to 12·6 of water, with occasionally a little starch, probably derived accidentally from the root, and not in sufficient quantity to cause a cold decoction of the gum-resin to give a blue colour with iodine. Mr. Hanbury, of London, found in the purest scammony in shells 91·1 per cent. of resin; and Mr. B. W. Bull, of New York, 86·88 per cent. in a specimen in irregular lumps, received from Constantinople as Aleppo Scammony. (*N. Y. Journ. of Pharm.*, June, 1852.) For the character of the resin, see *Extractum* sive *Resina Scammonii*. As already stated, scammony is seldom or never quite pure as found in our shops. Much of it contains not more than 50 per cent. of the resin, some not more than 42 per cent., and the worst varieties as little as 10 per cent., or even less.* Sometimes the cakes are of good quality on the outside, and inferior within. (Bull, *N. Y. Journ. of Pharm.*, i. 7.) It has been suggested, in this uncertainty as to the strength of the scammony of the shops, whether it might not be best to abandon its internal use altogether, and to substitute its resin, which is of uniform strength.

The Edinburgh College gives the following signs of pure scammony, "Fracture glistening, almost resinous, if the specimen be old and dry; muriatic acid does not cause effervescence on its surface; the decoction of its powder, filtered and cooled, is not rendered blue by tincture of iodine. Sulphuric ether separates at least eighty per cent. of resin dried at 280°." Effervescence with muriatic acid indicates the presence of chalk, a blue colour with iodine that of starch in the form of flour.

Factitious Scammony. Montpellier Scammony. Much spurious scammony is manufactured in the South of France, said to be made from the expressed juice of *Cynanchum Monspeliacum*, incorporated with various resins, and other purgative substances.† It has been occasionally imported into the United States, and sold as Smyrna scammony. It is usually in flat semicircular cakes, four or five inches in diameter, and six or eight lines thick, blackish both externally and

* The following table is given by Dr. Christison as the result of his examination of different specimens of impure commercial scammony.

† This statement as to the employment of Cynanchum Monspeliacum is made on the authority of Guibourt. M. Thorel, a pharmaceutist of Avallon, denies that this plant is employed in its preparation. (*Journ. de Pharm.*, xx. 107.)

within, very hard, compact, rather heavy, of a somewhat shining and resinous fracture, a feeble balsamic odour wholly different from that of genuine scammony, and a very bitter nauseous taste. When rubbed with the moistened finger it becomes dark-gray, unctuous, and tenacious. We have seen another substance sold as Smyrna scammony, which was obviously spurious, consisting of blackish, circular, flat cakes, or fragments of such cakes, rather more than half an inch thick, very light, penetrated with small holes as if worm eaten, and when broken exhibiting an irregular, cellular, spongy texture. Dr. Pereira describes a factitious substance sold as *Smyrna scammony*, which is in circular flat cakes, about half an inch thick, blackish, and of a slaty aspect, breaking with difficulty, of a dull black fracture, and of the sp. gr. 1·412. Moistened and rubbed it has the smell of guaiac, which may also be detected by chemical tests.

Medical Properties and Uses. Scammony is an energetic cathartic, apt to occasion griping, and sometimes operating with harshness. It was known to the ancient Greek physicians, and was much employed by the Arabians, who not only gave it as a purgative, but also applied it externally for the cure of various cutaneous diseases. It may be used in all cases of torpid bowels, when a powerful impression is desired; but on account of its occasional violence is seldom administered, except in combination with other cathartics, the action of which it promotes, while its own harshness is mitigated. It should be given in emulsion with mucilage, sugar, almonds, liquorice, or other demulcent; and its disposition to gripe may be counteracted by the addition of an aromatic. The dose is from five to fifteen grains of pure scammony, from ten to thirty of that commonly found in the market.

Gen. Ch. Corolla six-petaled, spreading, deciduous. *Filaments* thread-like. *Willd.*

Scilla maritima. Willd. *Sp. Plant.* ii. 125; Woodv. *Med. Bot.* p. 745, t. 255.—*Squilla maritima.* Steinheil; Lindley, *Flor. Med.* p. 591; Carson, *Illust. of Med. Bot.* ii. 46, pl. 89. This is a perennial plant, with fibrous roots proceeding from the bottom of a large bulb, which sends forth several long, lanceolate, pointed, somewhat undulated, shining, deep-green leaves. From the midst of the leaves a round, smooth, succulent flower-stem rises, from one to three feet high, terminating in a long, close spike of whitish flowers. These are destitute of calyx, and stand on purplish peduncles, at the base of each of which is a linear, twisted, deciduous floral leaf.

The squill grows on the sea-coast of Spain, France, Italy, Greece, and the other countries bordering on the Mediterranean. The bulb is the officinal portion. It is generally dried for use; but is sometimes imported into this country in the recent state packed in sand.

Properties. The fresh bulb is pear-shaped, usually larger than a man's fist, sometimes as large as the head of a child, and consisting of fleshy scales attenuated at their edges, closely applied over each other, and invested by exterior scales so thin and dry as to appear to constitute a membranous coat. There are two

varieties, distinguished as the *red* and *white squill*. In the former, the exterior coating is of a deep reddish-brown colour, and the inner scales have a whitish rosy or very light pink epidermis, with a yellowish-white parenchyma; in the latter, the whole bulb is white. They do not differ in their medicinal virtues. The bulb abounds in a viscid, very acrid juice, which causes it to inflame and even excoriate the skin when much handled. By drying, this acrimony is very much diminished, with little loss of medicinal power. The bulb loses about four-fifths of its weight in the process. Vogel found 100 parts of fresh squill to be reduced to 18 by desiccation. The process is somewhat difficult, in consequence of the abundance and viscid character of the juice. The bulb is cut into thin transverse slices, and the pieces dried separately by artificial or solar heat. The outer and central scales are rejected, the former being dry and destitute of the active principle, the latter too fleshy and mucilaginous. The London College gives directions for the slicing and drying of the recent bulb.

Dried squill, as found in our shops, is in irregular oblong pieces, often more or less contorted, of a dull yellowish-white colour with a reddish or rosy tint, sometimes entirely white, slightly diaphanous, brittle and pulverizable when perfectly dry, but often flexible from the presence of moisture, for which they have a great affinity. Occasionally a parcel will be found consisting of vertical slices, some of which adhere together at the base. The odour is very feeble, the taste bitter, nauseous, and acrid.

The virtues of squill are extracted by water, alcohol, and vinegar. According to Vogel, it contains a bitter principle named by him *scillitin*, gum, tannin, citrate of lime and saccharine matter, lignin, and an acrid principle which he was unable to isolate. Water distilled from it had neither taste nor smell, and was drunk by Vogel to the amount of six ounces without effect. From the experiments of Duncan and Buchner, it appears that tannin, if it exists in squill, is in very small proportion. The *scillitin* of Vogel was soluble in water, alcohol, and vinegar; but was considered by M. Tilloy, of Dijon, to be a compound of the proper active principle of squill with gum and uncrystallizable sugar. The *scillitin*, obtained by the latter experimenter, was insoluble in water and dilute acids, soluble in alcohol, exceedingly acrid and bitter, and very powerful in its influence on the system. A single grain produced the death of a strong dog. The process of Tilloy may be seen in former editions of this work. The scillitin obtained by him was still impure. Labourdais believed that he had obtained it in an isolated state by means of animal charcoal. A decoction of squill was first treated with acetate of lead to separate the viscid matters, was then filtered and agitated in the cold with purified animal charcoal in fine powder, and afterwards allowed to rest. The charcoal gradually subsided, carrying with it the bitter and colouring principles. The liquid being decanted, the solid matter was dried, and treated with hot alcohol, which acquired an insupportable bitterness. The alcohol being distilled off, left a milky liquid, which was allowed to evaporate spontaneously. The scillitin thus procured was solid, uncrystallized, easily decomposable by heat, almost caustic to the taste, not deliquescent, neuter, but slightly soluble in water, to which, however, it imparted a very great bitterness, very soluble in alcohol, and dissolved, but at the same time decomposed by concentrated sulphuric and nitric acids, imparting to the former a purple colour, instantly becoming black. (*Ann. de Thérap.*, 1849, p. 145.) L. F. Bley succeeded in obtaining scillitin, by the process of Labourdais, in long flexible needle-shaped crystals, by simply allowing the last alcoholic solution to evaporate spontaneously. (*Arch. der Pharm.*, lxi. 141.) Landerer obtained a crystalline principle from fresh squill, by treating the bruised bulb with dilute sulphuric acid, concentrating the solution, neutralizing it with lime, drying the precipitate, exhausting this with alcohol, and evaporating the tincture, which, on cooling, deposited the substance in question in prismatic crystals. It was bitter, but not

acrid, insoluble in water or the volatile oils, slightly soluble in alcohol, and, according to Landerer, capable of neutralizing the acids. (*Christison's Dispensatory.*) Wittstein inferred from his experiments that the bitterness and acrimony of squill reside in distinct principles. (See *Pharm. Journ. and Trans.*, x. 359.) Tilloy has recently made a new analysis of squill, which he finds to contain, 1. a resinoid substance very acrid and poisonous, soluble in alcohol and not in ether, 2. a very bitter principle, yellow, and soluble in water and alcohol, 3. a fatty matter soluble in ether and not in alcohol, 4. citrate of lime, and 5. mucilage and sugar. The acrid principle, in the dose of about three quarters of a grain, killed a dog. The bitter principle is much less powerful. Both are contained in the matters extracted from squill by means of animal charcoal. The citrate of lime is in the form of minute, silky, acicular crystals, interspersed through the parenchyma of the bulb. (*Journ. de Pharm.*, 3*e sér.*, xxiii. 410.)

When kept in a dry place, squill retains its virtues for a long time; but if exposed to moisture it soon becomes mouldy.

Medical Properties and Uses. Squill is expectorant, diuretic, and in large doses emetic and purgative. In over-doses it has been known to occasion hypercatharsis, strangury, bloody urine, and fatal inflammation of the stomach and bowels. The Greek physicians employed it as a medicine; and it has retained to the present period a deserved popularity. As an expectorant, it is used both in cases of deficient and of superabundant secretion from the bronchial mucous membrane; in the former case usually combined with tartar emetic or ipecacuanha, in the latter frequently with the stimulant expectorants. In both instances, it operates by stimulating the vessels of the lungs; and, where the inflammatory action in this organ is considerable, as in pneumonia and severe catarrh, the use of squill should be preceded by the lancet. In dropsical diseases it is very much employed, especially in connexion with calomel, which is supposed to excite the absorbents, while the squill increases the secretory action of the kidneys. It is thought to succeed best, in these complaints, in the absence of general inflammatory excitement. On account of its great uncertainty and occasional harshness, it is very seldom prescribed as an emetic, except in infantile croup or catarrh, in which it is usually given in the form of syrup or oxymel. When given in substance, it is most conveniently administered in the form of pill. The dose, as a diuretic or expectorant, is one or two grains repeated two or three times a day, and gradually increased till it produces slight nausea, or evinces its action upon the kidneys or lungs. From six to twelve grains will generally vomit. The vinegar and syrup of squill are officinal, and much used. An *acetic extract* has been prepared by Mr. F. D. Niblett, by digesting a pound of squill with three fluidounces of acetic acid and a pint of distilled water, with a gentle heat, for forty-eight hours, then expressing, and, without filtration, evaporating to a proper consistence. One grain is equal to about three of the powder. (*Pharm. Journ. and Trans.*, xii. 133.)

Cytisus Scoparius. De Cand. *Prodrom.* ii. 154.—*Spartium Scoparium.* Willd. *Sp. Plant.* iii. 933; Woodv. *Med. Bot.* p. 413, t. 150. This is a common European shrub, cultivated in our gardens, from three to eight feet high, with numerous straight, pentangular, bright-green, very flexible branches, and small, oblong, downy leaves, which are usually ternate, but on the upper part of the plant are sometimes simple. The flowers are numerous, papilionaceous, large, showy, of a golden-yellow colour, and supported solitarily upon short axillary peduncles. The seeds are contained in a compressed legume, which is hairy at the sutures.

The whole plant has a bitter nauseous taste, and, when bruised, a strong peculiar odour. The tops of the branches are the officinal portion; but the seeds are also used, and, while they possess similar virtues, have the advantage of keeping better. Water and alcohol extract their active properties. According to Cadet de Gassicourt, the flowers contain volatile oil, fatty matter, wax, chlorophylle, yellow colouring matter, tannin, a sweet substance, mucilage, osmazome, albumen and lignin. Dr. Stenhouse has separated from them two principles, one of which called *scoparin* he believes to be the diuretic principle, and the other, named *spartein*, to be narcotic. The former is in stellate crystals, easily dissolved by boiling water and alcohol, and is obtained by purifying a yellow gelatinous substance deposited upon the evaporation of the decoction. It may be given in the dose of four or five grains. The latter was obtained by distillation from the mother waters of the scoparin. It is a colourless liquid, having a peculiar bitter taste, and all the properties of a volatile organic base. It appears to have narcotic properties. But we need more definite information on the subject. (*Ann. de Thérap.*, A. D. 1853, p. 153.)

Medical Properties and Uses. Broom is diuretic and cathartic, and in large doses emetic, and has been employed with great advantage in dropsical complaints, in which it was recommended by Mead, Cullen, and others. Cullen prescribed it in the form of decoction, made by boiling half an ounce of the fresh tops in a pint of water down to half a pint, of which he gave a fluidounce every hour till it operated by stool or urine. It is a domestic remedy in Great Britain, but is seldom used in this country. The seeds may be given in powder, in the dose of ten or fifteen grains.

SENEGA. *U. S., Lond., Ed., Dub.*

Seneka.

The root of Polygala Senega. *U. S., Lond., Ed., Dub.*

Polygale de Virginie, *Fr.;* Klapperschlangenwurzel, *Germ.;* Poligala Virginiana, *Ital.*

Polygala. *Sex. Syst.* Diadelphia Octandria.—*Nat. Ord.* Polygalaceæ.

Gen. Ch. Calyx five-leaved, with two leaflets wing-shaped, and coloured. *Legume* obcordate, two-celled. *Willd.*

Besides *P. Senega*, two other species have attracted some attention in Europe—*P. amara* and *P. vulgaris*—as remedies in chronic pectoral affections; but as they are not natives of this country, and are never used by practitioners here, they do not merit particular notice.

Polygala Senega. Willd. *Sp. Plant.* iii. 894; Bigelow, *Am. Med. Bot.* ii. 97; Barton, *Med. Bot.* ii. 111. This unostentatious plant has a perennial branching root, from which several erect, simple, smooth, round, leafy stems annually rise, from nine inches to a foot in height. The stems are occasionally tinged

with red or purple below, but are green near the top. The leaves are alternate or scattered, lanceolate, pointed, smooth, bright-green on the upper surface, paler beneath, and sessile or supported on very short footstalks. The flowers are small and white, and form a close spike at the summit of the stem. The calyx is their most conspicuous part. It consists of five leaflets, two of which are wing-shaped, white, and larger than the others. The corolla is small and closed. The capsules are small, much compressed, obcordate, two-valved, and two-celled, with two oblong-ovate, blackish seeds, pointed at one end.

This species of Polygala, commonly called *Seneka snakeroot*, grows wild in all parts of the United States, but most abundantly in the southern and western sections, where the root is collected for sale. It is brought into market in bales weighing from fifty to four hundred pounds.

Properties. As the root occurs in commerce, it is of various sizes, from that of a straw to that of the little finger, presenting a thick knotty head, which exhibits traces of the numerous stems. It is tapering, branched, variously twisted, often marked with crowded annular protuberances, and with a projecting keel-like line, extending along its whole length. The epidermis is corrugated, transversely cracked, of a yellowish-brown colour in the young roots, and brownish gray in the old. In the smaller branches the colour is a lighter yellow. The bark is hard and resinous, and contains the active principles of the root. The central portion is ligneous, white, and quite inert, and should be rejected in the preparation of the powder. The colour of this is gray. The odour of seneka is peculiar, strong in the fresh root, but faint in the dried. The taste is at first sweetish and mucilaginous, but after chewing becomes somewhat pungent and acrid, leaving a peculiar irritating sensation in the fauces. These properties, as well as the medical virtues of the root, are extracted by boiling water, and by alcohol. Diluted alcohol is an excellent solvent. The root has been analyzed by Gehlen, Peschier of Geneva, Feneulle of Cambray, Dulong D'Astafort, Folchi, and Trommsdorff, and more recently by M. Quevenne. Gehlen was supposed to have found the active principle in the substance left behind, when the alcoholic extract is treated successively with ether and water; and the name of *senegin* was accordingly conferred upon it. But it does not seem to have any just claim to the rank assigned to it, though it probably contains the active principle among its constituents. From a comparison of the results obtained by the above-mentioned chemists, it would appear that seneka contains, 1. a peculiar acrid principle, which M. Quevenne considers to be an acid, and has named *polygalic acid;* 2. a yellow colouring matter, of a bitter taste, insoluble or nearly so in water, but soluble in ether and alcohol; 3. a volatile principle, considered by some as an essential oil, but thought by Quevenne to possess acid properties, and named by him *virgineic acid;* 4. pectic acid or pectin; 5. tannic acid of the variety which precipitates iron green; 6. gum; 7. albumen; 8. cerin; 9. fixed oil; 10. woody fibre; and 11. saline and earthy substances, as the carbonates, sulphates, and phosphates of lime and potassa, chloride of potassium, alumina, magnesia, silica, and iron. The virtues of seneka appear to reside chiefly, if not exclusively, in the acrid principle which M. Quevenne called polygalic acid, and which he considered closely analogous to saponin. He obtained it pure by the following process. Powdered seneka is exhausted by alcohol of 33°, and so much of the alcohol is distilled off as to bring the resulting tincture to the consistence of syrup. The residue is treated with ether, in order to remove the fatty matter. The liquid upon standing deposits a precipitate, which is separated by filtration, and is then mixed with water. To the turbid solution thus formed alcohol is added, which facilitates the production of a white precipitate, consisting chiefly of polygalic acid. The liquid is allowed to stand for several days, that the precipitate may be fully formed. The supernatant liquid being decanted, the pre-

cipitate is drained upon a filter, and, being removed while yet moist, is dissolved by the aid of heat in alcohol of 36°. The solution is boiled with purified animal charcoal, and filtered while hot. Upon cooling it deposits the principle in question in a state of purity. Thus obtained, polygalic acid is a white powder, inodorous, and of a taste at first slight, but soon becoming pungent and acrid, and producing a very painful sensation in the throat. It is fixed, unalterable in the air, inflammable, soluble in water slowly when cold and rapidly with the aid of heat, soluble in all proportions in boiling absolute alcohol, which deposits most of it on cooling, quite insoluble in ether and in the fixed and volatile oils, and possessed of the properties of reddening litmus and neutralizing the alkalies. Its constituents are carbon, hydrogen, and oxygen. M. Quevenne found it, when given to dogs, to occasion vomiting and much embarrassment in respiration, and in large quantities to destroy life. Dissection exhibited evidences of inflammation of the lungs, and frothy mucus was found in the stomach, œsophagus, and superior portion of the trachea, showing the tendency of this substance to increase the mucous secretion, and explaining in part the beneficial influence of seneka in croup. (*Journ. de Pharm.*, xxii. 449, and xxiii. 227.)

From the experiments of M. Quevenne it also appears that seneka yields its virtues to water, cold or hot, and to boiling alcohol; and that the extracts obtained by means of these liquids have the sensible properties of the root. But, under the influence of heat, a portion of the acrid principle unites with the colouring matter and coagulated albumen, and thus becomes insoluble in water; and the decoction, therefore, is not so strong as the infusion, if time is allowed, in the formation of the latter, for the full action of the menstruum. If it be desirable to obtain the virtues of the root in the form of an aqueous extract, the infusion should be prepared on the principle of displacement; as it is thus most concentrated, and consequently requires less heat in its evaporation. In forming an infusion of seneka, the temperature of the water, according to M. Quevenne, should not exceed 104° F. (*Ibid.*)

The roots of *Panax quinquefolium* or ginseng are frequently mixed with the seneka, but are easily distinguishable by their shape and taste. Another root has been occasionally observed in parcels of seneka, supposed to be that of Gillenia trifoliata. This would be readily distinguished by its colour and shape (see *Gillenia*), and by its bitter taste without acrimony. One of the most characteristic marks of seneka is the projecting line running the whole length of the root, and appearing as though a thread were placed beneath the bark, and, being attached at the upper end, were drawn at the lower, so as to give the root a contorted shape.

Medical Properties and Uses. Seneka is a stimulating expectorant and diuretic, and in large doses emetic and cathartic. It appears indeed to excite more or less all the secretions, proving occasionally diaphoretic and emmenagogue, and increasing the flow of saliva. Its action, however, is especially directed to the lungs; and its expectorant virtues are those for which it is chiefly employed. It was introduced into practice about a century ago by Dr. Tennant, of Virginia, who recommended it as a cure for the bite of the rattlesnake, and in various pectoral complaints. As an expectorant it is employed in cases not attended with acute inflammatory action, or in which the inflammation has been in great measure subdued. It is peculiarly useful in chronic catarrhal affections, the secondary stages of croup, and in peripneumonia notha after sufficient depletion. By Dr. Archer, of Maryland, it was recommended in the early stages of croup; but under these circumstances it is now seldom given, unless in combination with squill and an antimonial, as in the *Syrupus Scillæ Compositus*. Employed so as to purge and vomit, it has proved useful in rheumatism; and some cases of dropsy are said to have been cured by it. It has also been recommended in amenorrhœa.

The dose of powdered seneka is from ten to twenty grains; but the medicine is more frequently administered in decoction. (See *Decoctum Seneyæ.*) There is an officinal syrup. An extract is prepared by macerating sixteen ounces of coarsely powdered senega, for two days, in three pints of a liquid consisting of one measure of alcohol and two of water; then putting the mixture into a percolator, and pouring upon it a similar fluid until six pints of filtered liquor are obtained; and, lastly, evaporating by means of a water-bath to the consistence of an extract. The dose is from one to three grains. (*Am. Journ. of Pharm.*, xiv. 287.) A tincture may also be prepared, but is not much employed. Polygalic acid may be employed in the dose of from the fourth to the half of a grain, dissolved in hot water, with the addition of gum and sugar.

Cassia. See CASSIA FISTULA.

The plants which yield senna belong to the genus Cassia, of which several species contribute to furnish the drug. These were confounded together by Linnæus in a single species, which he named Cassia Senna. Since his time the subject has been more thoroughly investigated, especially by Delile, who accompanied the French expedition to Egypt, and had an opportunity of examining the plant in its native country. Botanists at present distinguish at least three species, C. acutifolia, C. obovata, and C. elongata, as the sources of commercial senna; and it is probable that two others, *C. lanceolata* of Forskhal and *C. Æthiopica* of Guibourt, contribute towards it. The first three are recognised by the U. S. Pharmacopœia.

1. *Cassia acutifolia.* Delile, *Flore d'Egypte*, lxxv. tab. 27, f. 1—*C. lanceolata.* De Candolle; Carson, *Illust. of Med. Bot.* i. 34, pl. 27. This is described as a small undershrub, two or three feet high, with a straight, woody, branching, whitish stem; but, according to Landerer, the senna plant attains the height of eight or ten feet in the African deserts, and affords the natives shelter from the sun. (See *Am. Journ. of Pharm.*, xviii. 174.) The leaves are alternate and pinnate, with glandless footstalks, and two small narrow pointed stipules at the base. The leaflets, of which from four to six pairs belong to each leaf, are almost sessile, oval-lanceolate, acute, oblique at their base, nerved, from half an inch to an inch long, and of a yellowish-green colour. The flowers are yellow, and in axillary spikes. The fruit is a flat, elliptical, obtuse, membranous, smooth, grayish-brown, bivalvular legume, about an inch long and half an inch broad, scarcely if at all curved, and divided into six or seven cells, each containing a hard, heart-shaped, ash-coloured seed. C. acutifolia grows wild in great abundance in Upper Egypt near Sienne, in Nubia, Sennaar, and probably in other parts of Africa having similar qualities of soil and climate. This species furnishes the greater part of that variety of senna, known in commerce by the title of Alexandria senna.

2. *Cassia obovata.* Colladon, *Monographie des Casses;* De Cand. *Prodrom.* ii. 492; Carson, *Illust. of Med. Bot.* i. 35, pl. 28. The stem of this species is rather shorter than that of C. acutifolia, rising to the height of only a foot and a half. The leaves have from five to seven pairs of leaflets, which are obovate, very obtuse, sometimes mucronate, in other respects similar to those of the preceding species. The flowers are in axillary spikes, of which the peduncles are longer than the leaves of the plant. The legumes are very much compressed, curved almost into the kidney form, of a greenish-brown colour, and covered with a very short down, which is perceptible only by the aid of a magnifying glass. They contain from eight to ten seeds. The *C. obtusata* of Hayne, with obovate, truncated, emarginate leaflets, is probably a mere variety of this species. The plant, which according to Merat is annual, grows wild in Syria, Egypt, and Senegambia; and is said to have been cultivated successfully in Italy, Spain, and the West Indies. It yields the variety of senna called in Europe Aleppo senna, and contributes to the packages of the Alexandrian.

3. *Cassia elongata.* Lemaire, *Journ. de Pharm.* vii. 345; Fée, *Journ. de Chim. Méd.* vi. 232; Carson, *Illust. of Med. Bot.* i. 36, pl. 29. This name was conferred by M. Lemaire upon the plant from which the India senna of commerce is derived. The botanical description was completed by M. Fée, from dried specimens of the leaves and fruit found by him in unassorted parcels of this variety of senna. Dr. Wallich has subsequently succeeded in raising the plant from seeds found in a parcel of senna taken to Calcutta from Arabia; and it has been described by Dr. Royle, Wight & Arnott, and Dr. Lindley. As usually grown, it is annual; but with care it may be made to live through the year, and then assumes the character of an undershrub. It has an erect, smooth stem, and pinnate leaves, with from four to eight pairs of leaflets. These are nearly sessile, lanceolate, obscurely mucronate, oblique at the base, smooth above and somewhat downy beneath, with the veins turned inwards so as to form a wavy line immediately within the edge of the leaflet. The most striking character of the leaflet is its length, which varies from an inch to twenty lines. The petioles are without glands; the stipules minute, spreading, and semi-hastate. The flowers are bright yellow, and arranged in axillary and terminal racemes, rather longer than the leaves. The legume is oblong, membranous, tapering abruptly at the base, rounded at the apex, and an inch and a half long by somewhat more than half an inch broad. This plant is a native of the southern parts of Arabia. It has been said also to grow in the interior of India, and is at present cultivated at Tinnevelly for medical use.

Besides the three officinal species above described, the *C. lanceolata* of Forskhal, found by that author growing in the deserts of Arabia, is admitted by Lindley and others as a distinct species. Some difference, however, of opinion exists upon this point. De Candolle considered it only a variety of the C. acutifolia of Delile, from the ordinary form of which it differs chiefly in having leaflets with glandular petioles; and, as Forskhal's description was prior to that of Delile, he designated the species by the name of C. lanceolata. Forskhal's plant has been supposed by some to be the source of the India and Mocha senna; but the leaflets in this variety are much longer than those of C. lanceolata, from which the plant differs also in having no gland on the petiole. Niebuhr informs us that he found the Alexandria senna growing in the Arabian territory of *Abuarish*, whence it is taken by the Arabs to Mecca and Jedda. This is probably the C. lanceolata of Forskhal. It is highly probable that this species is the source of a variety of senna which has been brought to this market under the name of Mecca senna.

The *Cassia Æthiopica* of Guibourt (*C. ovata* of Merat), formerly confounded with C. acutifolia, is considered by Dr. Lindley as undoubtedly a distinct species. It grows in Nubia, Fezzan to the south of Tripoli, and probably, according to

Guibourt, throughout Ethiopia. It is from this plant that the *Tripoli senna* of commerce is derived.*

Commercial History. Several varieties of this valuable drug are known in commerce. Of these, four have been received in America, the Alexandria, the Tripoli, the India, and the Mecca senna.

1. *Alexandria Senna.* Though the name of this variety is derived from the Egyptian port at which it is shipped, it is in fact gathered very far in the interior. The Alexandria senna does not consist exclusively of the product of one species of Cassia. The history of its preparation is not destitute of interest. The senna plants of Upper Egypt yield two crops annually, one in spring and the other in autumn. They are gathered chiefly in the country beyond Sienne. The natives cut the plants, and, having dried them in the sun, strip off the leaves and pods, which they pack in bales, and send to Boulac, in the vicinity of Cairo, the great entrepot for this article of Egyptian commerce. This senna from Upper Egypt, consisting chiefly though not exclusively of the product of C. acutifolia, was here formerly mixed with the leaflets of C. obovata, brought from other parts of Egypt, and even from Syria, with the leaves of *Cynanchum oleæfolium* (*C. Argel* of Delile), known commonly by the name of *argel* or *arguel*, and sometimes with those of the *Tephrosia Apollinea* of De Candolle, a leguminous plant growing in Egypt and Nubia. According to M. Royer, the proportions in which the three chief constituents of this mixture were added together, were five parts of C. acutifolia, three of C. obovata, and two of Cynanchum. Thus prepared, the senna was again packed in bales, and transmitted to Alexandria. But at present there is no such uniformity in the constitution of Alexandria senna; and, though the three chief ingredients may still sometimes be found in it, they are not in the same fixed proportions; and not unfrequently the Cynanchum leaves are wholly wanting. This commercial variety of senna is often called in the French pharmaceutic works *séné de la palthe*, a name derived from an impost formerly laid upon it by the Ottoman Porte.

A parcel of Alexandria senna, as it was formerly brought to market, consisted of the following ingredients:—1. The leaflets of C. acutifolia, characterized by their acute form, and their length almost always less than an inch; 2. the leaflets of C. obovata, known by their rounded very obtuse summit, which is sometimes furnished with a small projecting point, and by their gradual diminution in breadth towards their base; 3. the pods, broken leafstalks, flowers, and fine fragments of other parts of one or both of these species; 4. the leaves of Cynanchum oleæfolium, which are distinguishable by their length, almost always more than an inch, their greater thickness and firmness, the absence of any visible lateral nerves on their under surface, their somewhat lighter colour, and the regularity of their base. In this last character they strikingly differ from the genuine senna leaflets, which, from whatever species derived, are always marked by obliquity at their base, one side being inserted in the petiole at a point somewhat lower than

* The following is the botanical description of the two species last mentioned, not hitherto officinally recognised.

1. *C. lanceolata.* Forskhal; Lindley, *Flor. Med.* p. 259. "Leaflets in four or five pairs, never more; oblong, and either acute or obtuse, not at all ovate or lanceolate, and perfectly free from downiness even when young; the petioles have constantly a small round brown gland a little above the base. The pods are erect, oblong, tapering to the base, obtuse, turgid, mucronate, rather falcate, especially when young, at which time they are sparingly covered with coarse scattered hairs." (*Lindley.*)

2. *C. Æthiopica.* Guibourt, *Hist. Ab. des Drogues, &c.* ii. 219; Lindley, *Flor. Med.* p. 259. The plant is about eighteen inches high. The footstalks have a gland at the base, and another between each pair of leaflets. There are from three to five pairs of leaflets, which are pubescent, oval-lanceolate, from seven to nine lines in length, and three or four in breadth, rather shorter and less acute than those of C. acutifolia. The legume is flat, smooth, not reniform, rounded, from eleven to fifteen lines long, with from three to five seeds.

the other, and at a different angle. The discrimination between this and the other ingredients is a matter of some consequence, as the cynanchum must be considered an adulteration. It is said by the French writers to occasion hypercatharsis and much irritation of the bowels; but was found by Christison and Mayer to occasion a griping, and severe protracted nausea, with little purgation. The flowers and fruit of the Cynanchum were also often present, the former of a white colour, and in small corymbs, the latter an ovoid follicle rather larger than an orange seed. Besides the above constituents of Alexandria senna, it occasionally contained leaflets of genuine senna, much longer than those of the acutifolia or obovata, equalling in this respect the cynanchum, which they also somewhat resembled in form. They were distinguishable, however, by their greater thinness, the distinctness of their lateral nerves, and the irregularity of their base. The leaflets and fruit of *Tephrosia Apollinea*, which have been an occasional impurity in this variety of senna, may be distinguished, the former by their downy surface, their obovate-oblong, emarginate shape, their parallel unbranched lateral nerves, and by being usually folded longitudinally; the latter, by its dimensions, being from an inch to an inch and a half long, and only two lines broad. As now imported, the Alexandria senna is often quite free from the leaves of the Cynanchum, and may have few or none of the leaflets of the obovate senna. It is probably brought directly to Alexandria from Upper Egypt, without having undergone any intermixture at Boulac or other intervening place. In Europe, this senna is said to have been sometimes adulterated with the leaflets of *Collutea arborescens* or bladder senna, and the leaves of *Coriaria myrtifolia*, a plant of Southern Europe, said to be astringent and even poisonous. An account of the former of these plants is given in the Appendix. The leaflets of the Coriaria are ovate-lanceolate, grayish-green with a bluish tint, and are readily known, when not too much broken up, by their strongly marked midrib, and two lateral nerves running from the base nearly to the summit. They are chemically distinguished by giving a whitish precipitate with solution of gelatin, and a bluish-black one with the salts of sesquioxide of iron, proving the presence of tannin. Their poisonous properties are denied by Peschier. According to Bouchardat, they are closely analogous to strychnia in their effect. (*Ann. de Thérap.*, 1843, p. 55.)

2. *Tripoli Senna.* Genuine Tripoli senna consists in general exclusively of the leaflets of one species of Cassia, which was formerly considered as a variety of *C. acutifolia*, but is now admitted to be distinct, and named *C. Æthiopica*. The leaflets, however, are much broken up; and it is probably on this account that the variety is usually less esteemed than the Alexandrian. The aspect given to it by this state of comminution, and by the uniformity of its constitution, enables the eye at once to distinguish it from the other varieties of senna. The leaflets, moreover, are shorter, less acute, thinner, and more fragile than those of the C. acutifolia in Alexandria senna; and their nerves are much less distinct. The general opinion at one time was, that it was brought from Sennaar and Nubia to Tripoli in caravans; but it is reasonably asked by M. Fée, how it could be afforded at a cheaper price than the Alexandrian, if thus brought on the backs of camels a distance of eight hundred leagues through the desert. It is probably collected in Fezzan, immediately south of Tripoli, and brought to that town for exportation.

3. *India Senna.* This variety is in Europe sometimes called *Mocha senna*, probably because obtained originally from that port. It derives its name of India senna from the route by which it reaches us. Though produced in Arabia, it is brought to this country and Europe from Calcutta, Bombay, and possibly other ports of Hindostan. It consists of the leaflets of Cassia elongata, with some of the leafstalks and pods intermixed. The eye is at once struck by the great

length and comparative narrowness of the leaflets, so that no difficulty can be experienced in distinguishing this variety. The pike-like shape of the leaflet has given rise to the name of *séné de la pique*, by which it is known in French pharmacy. Many of the leaflets have a yellowish, dark-brown, or blackish colour, probably from exposure after collection; and this variety has in mass a dull tawny hue which is not found in the others. It is generally considered inferior in purgative power.

A variety of India senna has recently reached this country, which is the produce of Hindostan, being cultivated at Tinnevelly, and probably other places in the South of the Peninsula. The plant was originally raised from seeds obtained from the Red Sea, and is the same as that from which the common India senna is derived. The drug is exported from Madras to England, where it is known by the name of *Tinnevelly senna*. It is a very fine unmixed variety, consisting of unbroken leaflets, from one to two or more inches in length, and sometimes half an inch in their greatest breadth, thin, flexible, and of a fine green colour.

4. *Mecca Senna.* Since the publication of the fifth edition of this Dispensatory, a variety of senna has been imported under the name of *Mecca senna*, consisting of the leaflets, pods, broken stems, and petioles of a single species of Cassia. The leaflets are oblong-lanceolate, on the average longer and narrower than those of C. acutifolia, and shorter than those of C. elongata. The variety in mass has a yellowish or tawny hue, more like that of India than that of Alexandria senna. May it not be the product of the C. lanceolata of Forskhal? Landerer, however, speaks of a valuable variety of senna, characterized by the large size of the leaflets, and sold under the name of Mecca senna, which he says comes from the interior of Africa.

Commercial senna is prepared for use by picking out the leaflets, and rejecting the leafstalks, the small fragments, and the leaves of other plants. The pods are also rejected by some apothecaries; but they possess considerable cathartic power, though said to be milder than the leaves.

Properties. The odour of senna is faint and sickly; the taste slightly bitter, sweetish, and nauseous. Water and diluted alcohol extract its active principles. Pure alcohol extracts them but imperfectly. (Bley and Diesel, *Pharm. Central Blatt.*, Feb. 1849, p. 126.) The leaves are said to yield about one-third of their weight to boiling water. The infusion is of a deep reddish-brown colour, and has the odour and taste of the leaves. When exposed to the air for a short time, it deposits a yellowish insoluble precipitate, supposed to result from the union of extractive matter with oxygen. The nature of this precipitate, however, is not well understood. Decoction also produces some change in the principles of senna, by which its medicinal virtues have been supposed to be impaired; but some experiments of B. Heerlein would seem to show that this opinion is incorrect. An extract prepared by boiling down an infusion, redissolving the residue, and again boiling down to a solid consistence, was found to operate actively in a dose equivalent to a drachm of the leaves. (*Pharm. Cent. Blatt*, A. D. 1851, p. 909.) To diluted alcohol it imparts the same reddish-brown colour as to water; but rectified alcohol and ether digested upon the powdered leaves become of a deep olive-green. The analysis of senna by MM. Lassaigne and Feneulle furnished the following results. The leaves contain—1. a peculiar principle called cathartin; 2. chlorophylle or the green colouring matter of leaves; 3. a fixed oil; 4. a small quantity of volatile oil; 5. albumen; 6. a yellow colouring matter; 7. mucilage; 8. salts of the vegetable acids, viz., malate and tartrate of lime and acetate of potassa; and 9. mineral salts. The pods are composed of the same principles, with the exception of the chlorophylle, the place of which is supplied by a peculiar colouring matter. (*Journ. de Pharm.*,

vii. 548, and ix. 58.) *Cathartin* was at one time believed to be the active principle of senna; but upon trial it has proved to possess little power of affecting the system; and it is now believed to be a complex body, consisting, according to Bley and Diesel, of a mixture of resinous and extractive matter. It is an uncrystallizable substance, having a peculiar smell, a bitter, nauseous taste, and a reddish-yellow colour; is soluble in every proportion in water and alcohol, but insoluble in ether; and in its dry state attracts moisture from the air. It is prepared in the following manner. To a filtered decoction of senna the solution of acetate of lead is added; and the precipitate which forms is separated. A stream of hydrosulphuric acid (sulphuretted hydrogen) is then made to pass through the liquor in order to precipitate the lead, and the sulphuret produced is removed by filtration. The liquid is now evaporated to the consistence of an extract; the product is treated with rectified alcohol; and the alcoholic solution is evaporated. To the extract thus obtained sulphuric acid diluted with alcohol is added, in order to decompose the acetate of potassa which it contains; the sulphate of potassa is separated by filtration; the excess of sulphuric acid by acetate of lead; the excess of acetate of lead by hydrosulphuric acid; and the sulphuret of lead by another filtration. The liquid being now evaporated yields cathartin. Bley and Diesel found in senna a peculiar yellow resin which they name *chrysoretin*, a brown resin and brown extractive which they could not fully separate, pectin, gummy extractive, chlorophylle, fatty matter, and various salts. (*Pharm. Cent. Blatt*, Feb. 1849, p. 126.)

Incompatibles. Many substances produce precipitates with the infusion of senna; but it does not follow that they are all medicinally incompatible; as they may remove ingredients which have no therapeutical effect, and leave the active principles untouched. Cathartin is precipitated by the infusion of galls and the solution of subacetate of lead. Acetate of lead and tartarized antimony, which disturb the infusion, have no effect upon the solution of this principle.

Medical Properties and Uses. Senna was first used as a medicine by the Arabians. It was noticed in their writings so early as the ninth century; and the name itself is Arabic. It is a prompt, efficient, and very safe purgative, well calculated for fevers and febrile complaints, and other cases in which a decided but not violent impression is desired. An objection sometimes urged against it is that it is apt to produce severe griping. This effect, however, may be obviated by combining with the senna some aromatic, and some one of the alkaline salts, especially bitartrate of potassa, tartrate of potassa, or sulphate of magnesia. The explanation which attributes the griping property to the oxidized extractive, and its prevention by the saline substances to their influence in promoting the solubility of that principle, is not entirely satisfactory. The purgative effect of senna is considerably increased by combination with bitters; a fact which was noticed by Cullen, and has been abundantly confirmed by the experience of others. The decoction of guaiac is said to exert a similar influence. The dose of senna in powder is from half a drachm to two drachms; but its bulk renders it of inconvenient administration; and it is not often prescribed in this state. Besides, the powder is said to undergo decomposition, and to become mouldy on exposure to a damp air. The form of infusion is almost universally preferred. (See *Infusum Sennæ.*) The medicine is also used in the forms of confection, fluid extract, syrup, and tincture, all of which are officinal.

Senna taken by nurses is said to purge sucking infants, and an infusion injected into the veins operates as a cathartic.

ARISTOLOCHIA. *Sex. Syst.* Gynandria Hexandria.—*Nat. Ord.* Aristolochiaceæ.

Gen. Ch. Calyx none. *Corolla* one-petaled, ligulate, ventricose at the base. *Capsule* six-celled, many-seeded, inferior. *Willd.*

Numerous species of Aristolochia have been employed in medicine. The roots of all of them are tonic and stimulant, and, from their supposed possession of emmenagogue properties, have given origin to the name of the genus. *A. Clematitis*, *A. longa*, *A. rotunda*, and *A. Pistolochia* are still retained in many officinal catalogues of the continent of Europe, where they are indigenous. The root of *A. Clematitis* is very long, cylindrical, as thick as a goosequill or thicker, variously contorted, beset with the remains of the stems and radicles, of a grayish-brown colour, a strong peculiar odour, and an acrid bitter taste; that of *A. longa* is spindle-shaped, from a few inches to a foot in length, of the thickness of the thumb or more, fleshy, very brittle, grayish externally, brownish-yellow within, bitter, and of a strong disagreeable odour when fresh; that of *A. rotunda* is tuberous, roundish, heavy, fleshy, brownish on the exterior, grayish-yellow internally, and similar to the preceding in odour and taste; that of *A. Pistolochia* consists of numerous slender yellowish or brownish fibres, attached to a common head, and possessed of an agreeable aromatic odour, with a taste bitter and somewhat acrid. Many species of Aristolochia growing in the West Indies, Mexico, and South America, have attracted attention for their medicinal properties, and some, like our own snakeroot, have acquired the reputation of antidotes for the bites of serpents. In the East Indies, *A. Indica* is employed for similar purposes with the European and American species; and the Arabians are said by Forskhal to use the leaves of *A. sempervirens* as a counter-poison. We have in the United States six species, of which four—*A. Serpentaria*, *A. hirsuta*, *A. hastata*, and *A. reticulata*—contribute to furnish the snakeroot of the shops.

Aristolochia Serpentaria. Willd. *Sp. Plant.* iv. 159; Bigelow, *Am. Med. Bot.* iii. 82; Barton, *Med. Bot.* ii. 41. This species of Aristolochia is an herbaceous plant with a perennial root, which consists of numerous slender fibres proceeding from a short horizontal caudex. Several stems often rise from the same root. They are about eight or ten inches in height, slender, round, flexuose, jointed at irregular distances, and frequently of a reddish or purple colour at the base. The leaves are oblong-cordate, acuminate, entire, of a pale yellowish-green colour, and supported on short petioles at the joints of the stem. The flowers proceed from the joints near the root, and stand singly on long, slender, round, jointed peduncles, which are sometimes furnished with one or two small scales, and bend downwards so as nearly to bury the flower in the earth or decayed leaves. There is no calyx. The corolla is purple, monopetalous, tubular, swelling at the base, contracted and curved in the middle, and terminating in a labiate border with lanceolate lips. The anthers—six or twelve in number—are sessile, attached to the under part of the stigma, which is roundish, divided into six parts, and supported by a short fleshy style upon an oblong, angular, hairy, inferior germ. The fruit is a hexangular, six-celled capsule, containing several small flat seeds.

The plant grows in rich, shady woods, throughout the Middle, Southern, and

Western States, abounding in the valley of the Ohio, and in the mountainous regions of our interior. It flowers in May and June. The root is collected in Western Pennsylvania and Virginia, in Ohio, Indiana, and Kentucky, and is brought eastward chiefly by the routes of Wheeling and Pittsburg. As it reaches Philadelphia, it is usually in bales containing about one hundred pounds, and is often mixed with the leaves and stems of the plant, and with dirt from which it has not been properly cleansed at the time of collection.

A. hirsuta. Muhlenberg, *Catalogue*, p. 81; Bridges, *Am. Journ. of Pharm.*, xiv. 121. In Muhlenberg's Catalogue this species was named without being described; and botanists, supposing from the name that it was identical with *A. tomentosa*, have generally confounded the two plants. But they are entirely distinct. A description of *A. hirsuta* in the handwriting of Muhlenberg, and a labelled specimen of the plant, in the possession of the Academy of Natural Sciences of this city, have been found to correspond with a dried specimen received by one of the authors of this work from Virginia. *A. tomentosa* is a climbing plant, growing in Louisiana on the banks of the Mississippi, ascending to the summit of the highest trees. A plant in the garden of the author has a thick creeping root, entirely different in shape from that of the officinal species, though possessed of an analogous odour. *A. hirsuta* has a root like that of *A. Serpentaria*, consisting of a knotty caudex, sending out numerous slender simple fibres, sometimes as much as six inches in length. From this arise several jointed, flexuose, pubescent stems, less than a foot high, with one or two pubescent bractes, and several large roundish-cordate leaves, of which the lower are obtuse, the upper abruptly acuminate, and all pubescent on both sides and at the margin. From the joints near the root originate from one to three solitary peduncles, each bearing three or four leafy bractes and one flower. The peduncles, bractes, and corolla are all hairy. This species grows in Virginia, and probably other parts of the Western and Southern States. There is reason to believe that it contributes to afford the serpentaria of commerce, as its leaves, at one time mistaken for those of *A. tomentosa*, have been found in bales of the drug.

A. hastata. Nuttall, *Gen. of N. Am. Plants*, p. 200.—*A. sagittata.* Muhl. *Catal.* This species, if indeed it can be considered a distinct species, differs from A. Serpentaria in having hastate, acute, somewhat cordate leaves, and the lip of the corolla ovate. It flourishes on the banks of the Mississippi, in the Carolinas, and elsewhere. Its root scarcely differs from that of the officinal plant, and is frequently mixed with it, as proved by the presence of the characteristic leaves of *A. hastata* in the parcels brought into market.

A. reticulata. Nuttall; Bridges, *Am. Journ. of Pharm.* xvi. 118; Carson, *Illust. of Med. Bot.* ii. 32, pl. 77. This plant was probably first observed by Mr. Nuttall; as a specimen labelled "*A. reticulata*, Red river," in the handwriting of that botanist, is contained in the Herbarium of the Academy of Natural Sciences of Philadelphia. From this specimen, as well as from others found in parcels of the drug brought into market, a description was drawn up by Dr. Robert Bridges, and published in the *Amer. Journ. of Pharmacy.* From a root, similar to that of *A. serpentaria*, numerous short, slender, round, flexuose, jointed stems arise, usually simple, but sometimes branched near the root. The older stems are slightly villous, the young densely pubescent. The leaves, which stand on very short villous petioles, are round or oblong-cordate, obtuse, reticulate, very prominently veined, and villous on both sides, especially upon the veins. From the lower joints of the stem four or five hairy, jointed peduncles proceed, which bear small leafy villous bractes at the joints, and several flowers on short pedicels. The flowers are small, purplish, and densely pubescent, especially at the base and on the germ. The hexangular capsule is deeply

sulcate. This species grows in Louisiana, Arkansas, and probably in the Indian Territory west of that State; but its geographical range has not been ascertained.

Bales of a new variety of serpentaria have within a few years been brought to Philadelphia, which is certainly the product of this species; as specimens of all parts of the plant have been found in the bales, and the roots, which differ somewhat from those before known, are homogeneous in character. One of these bales was brought from New Orleans, and was said to have come down the Red river, and to have been collected by the Indians. The chief difference between this and ordinary Virginia snakeroot is in the size of the radicles, which are much thicker and less interlaced in the new variety. Each root has usually a considerable portion of one or more stems attached to the caudex. The colour is yellowish. The odour and taste are scarcely, if at all distinguishable from those of common serpentaria; and there is no doubt that the root is equally effectual as a medicine. From a chemical examination by Mr. Thomas S. Wiegand, it appears to have the same constituents, and to differ only in containing a somewhat larger proportion of gum, extractive, and volatile oil. (*Am. Journ. of Pharm.*, xvi. 16.)

Properties. Virginia snakeroot, as found in the shops, is in tufts of long, slender, frequently interlaced, and brittle fibres, attached to a short, contorted, knotty head or caudex. The colour, which in the recent root is yellowish, becomes brown by time. That of the powder is grayish. The smell is strong, aromatic, and camphorous; the taste warm, very bitter, and also camphorous. The root yields all its virtues to water and alcohol, producing with the former a yellowish-brown infusion, with the latter a bright greenish tincture, which is rendered turbid by the addition of water. Chevallier found in the root volatile oil, a yellow bitter principle soluble in water and alcohol, resin, gum, starch, albumen, lignin, and various salts. Buchholz obtained from 1000 parts, 5 of a green, fragrant volatile oil, 28.5 of a yellowish-green resin, 17 of extractive matter, 181 of gummy extract, 624 of liguin, and 144·5 of water. The active ingredients are probably the volatile oil, and the yellow bitter principle of Chevallier, which that chemist considers analogous to the bitter principle of quassia. The volatile oil passes over with water in distillation, rendering the liquid milky, and impregnating it with the peculiar odour of the root. Dr. Bigelow states that the liquid on standing deposits around the edges of its surface small crystals of camphor.

The roots of *Spigelia Marilandica* are sometimes found associated with serpentaria. They may be distinguished by the absence of the bitter taste, and, when the stem and foliage are attached, by the peculiar character of these parts of the plant. (See *Spigelia.*) We have occasionally seen the young roots of *Polygala Senega* mixed with serpentaria. Independently of their difference in odour and taste, they may be readily distinguished by being single, and by the projecting line running from one end to the other of the root.

Medical Properties and Uses. Serpentaria is a stimulant tonic, acting also as a diaphoretic or diuretic, according to the mode of its application. Too largely taken, it occasions nausea, griping pains in the bowels, sometimes vomiting and dysenteric tenesmus. It is admirably adapted to the treatment of typhoid fevers, whether idiopathic or symptomatic, when the system begins to feel the necessity for support, but is unable to bear active stimulation. In exanthematous diseases in which the eruption is tardy or has receded, and the grade of action is low, it is thought to be useful by promoting the cutaneous affection. It has also been highly recommended in intermittent fevers; and though itself generally inadequate to the cure of the complaint, often proves serviceable as an adjunct to Peruvian bark or sulphate of quinia. With the same remedies it is frequently associated in the treatment of typhous diseases. It is sometimes given in dyspepsia, and is employed as a gargle in malignant sorethroat.

The dose of the powdered root is from ten to thirty grains; but the infusion is almost always preferred. (See *Infusum Serpentariæ.*) The decoction or extract would be an improper form; as the volatile oil, upon which the virtues of the medicine partly depend, is dissipated by boiling.*

Sesamum orientale. Willd. *Sp. Plant.* iii. 358; Rheed. *Hort. Malab.* ix. 54. "Leaves ovate, oblong, entire."

Sesamum Indicum. Willd. *Sp. Plant.* iii. 359; Curtis, *Bot. Mag.* vol. xli. t. 1688. "Leaves ovate-lanceolate, the inferior three-lobed, the superior undivided. Stem erect." There is reason to believe that this species is the one chiefly cultivated in our Southern States. At least we have found plants, raised in Philadelphia from seeds obtained from Georgia, to have its specific character, as given by Willdenow.

The benne plant of our Southern States is annual, with a branching stem four or five feet high, and bearing opposite, petiolate leaves, varying considerably in their shape. Those on the upper part of the plant are ovate-lanceolate, irregularly serrate, and pointed; those near the base three-lobed and sometimes ternate; and lobed leaves are not uncommon at all distances from the ground. The flowers are of a reddish-white colour, and stand solitarily upon short peduncles in the axils of the leaves. The fruit is an oblong capsule, containing small, oval, yellowish seeds.

These two species of Sesamum are natives of the East Indies, and have been cultivated from time immemorial in various parts of Asia and Africa. From the latter continent it is supposed that seeds were brought by the Negroes to the United States, where, as well as in the West Indies, one or both species are now cultivated to a considerable extent. It has been found that the plant above described will grow vigorously in the gardens so far north as Philadelphia, though it does not usually ripen its seeds in this vicinity.

* Mr. J. B. Savery proposes a *fluid extract of serpentaria*, made in the following manner. Eight ounces of the powdered root are macerated for a day or two in a pint of alcohol; and the mixture is then submitted to percolation, diluted alcohol being poured upon it until four pints have passed. The tincture thus obtained is evaporated by a gentle heat, with constant agitation, to twelve fluidounces, in which eight ounces of powdered sugar are dissolved, and the whole strained through flannel. A fluidounce contains the virtues of half an ounce of the root. From half a fluidrachm to a fluidrachm may be given for a dose. (*Am. Journ. of Pharm.*, xxiii. 120.)

The seeds are employed as food by the negroes, who parch them over the fire, boil them in broths, make them into puddings, and prepare them in various other modes. By expression they yield a fixed oil, which, as well as the leaves of the plant, has been introduced into the secondary catalogue of our national Pharmacopœia.

1. *Benne Leaves.* These abound in a gummy matter, which they readily impart to water, forming a rich, bland mucilage, much used in the Southern States as a drink in various complaints to which demulcents are applicable, as in cholera infantum, diarrhœa, dysentery, catarrh, and affections of the urinary passages. The remedy has attracted attention also in the North, and has been employed with favourable results in Philadelphia. One or two fresh leaves of full size, stirred about in half a pint of cool water, will soon render it sufficiently viscid. In their dried state they should be introduced into hot water. The leaves also serve for the preparation of emollient cataplasms.

2. *Benne Oil.* This is inodorous, of a bland, sweetish taste, and will keep long without becoming rancid. It bears some resemblance to olive oil in its properties, and may be used for similar purposes. It was known to the ancient Persians and Egyptians, and is highly esteemed by the modern Arabs and other people of the East, both as food and as an external application to promote softness of the skin. Like olive oil, it is laxative in large doses. W.

SEVUM. *U. S., Lond., Ed.*

Suet.

The prepared suet of Ovis Aries. *U. S., Lond., Ed.*

Suif, Graisse de mouton, *Fr.;* Hammelstalg, *Germ.;* Grasse duro, *Ital.;* Sebo, *Span.*

Suet is the fat of the sheep, taken chiefly from about the kidneys. It is prepared by cutting the fat into pieces, melting it with a moderate heat, and straining it through linen or flannel. In order to avoid too great a heat, the crude suet is sometimes purified by boiling it in a little water.

Mutton suet is of a firmer consistence, and requires a higher temperature for its fusion than any other animal fat. It is very white, sometimes brittle, inodorous, of a bland taste, insoluble in water, and nearly so in alcohol. Boiling alcohol, however, dissolves it, and deposits it upon cooling. It consists, according to Chevreul, of stearin, olein, and a small proportion of hircin. For an account of the two first-mentioned principles, the reader is referred to the article *Adeps*. *Hircin* is a liquid like olein, from which it differs in being much more soluble in alcohol, and in yielding *hircic acid* by saponification.

Suet acquires by time an unpleasant smell, and becomes unfit for pharmaceutic purposes. It is employed to give a proper consistence to ointments, cerates, and plasters, and sometimes as a dressing to blisters. W.

SILEX CONTRITUS. *Lond.*

Pulverized Silex.

Powdered flint, Silica, Silicic acid; Silice, *Fr.;* Kieselerde, *Germ.*

In operations of pharmacy, substances are sometimes employed whose action is exclusively mechanical. Thus, in the U. S. Pharmacopœia, sand is used in preparing oil of amber and the fluid extract of rhubarb, and carbonate of magnesia in forming several of the medicated waters. The use of the same carbonate was also directed in the London Pharmacopœia of 1836, in alternative processes for preparing several of these waters. Mr. R. Warington has objected to the

use of this carbonate, as being dissolved to an injurious extent, and proposed to substitute porcelain clay, or pulverized silica, glass, or pumice stone. (*Chem. Gaz.*, March 1, 1845.) The London College, probably influenced by this objection, has, in its Pharmacopœia of 1851, abandoned the use of carbonate of magnesia, and substituted finely pulverized silex, under the name of *Silex Contritus.*

This powder may be conveniently obtained from *colourless* quartz or rock-crystal. In order to render it more easily pulverizable, it is advantageous to heat it to redness, and quench it in water. It may then be reduced to fine powder in a porphyry or agate mortar.

Pulverized silex is a harsh, white, tasteless powder, insoluble in water and most other solvents. Its sp. gr. is 2·66. In composition it is generally considered to be a *teroxide of silicon*, consisting of one eq. of silicon 21·3, and three of oxygen 24=45·3.

The London College directs the use of pulverized silex in preparing all the medicated waters, except two, from the volatile oils of the plants, in addition to the method of distillation with water from the plants themselves. In the excepted cases (rose and elder water), distillation is alone allowed. The oil is rubbed up first with the silex and then with the water, and the whole is filtered. The silex acts as a mechanical agent in minutely dividing the oil and diffusing it through the water, and, by the subsequent filtration, is entirely removed.

QUASSIA. See QUASSIA.

Quassia Simaruba. Willd. *Sp. Plant.* ii. 568; Woodv. *Med. Bot.* p. 569, t. 203. —*Simaruba officinalis.* De Cand. *Prodrom.* i. 733.—*S. amara.* Aublet; Lindley, *Flor. Med.* p. 207. As this plant is unisexual, it belongs to the genus Simaruba of De Candolle and Lindley, those only being placed by these botanists in the genus Quassia which are hermaphrodite. But as the Linnæan arrangement was adhered to in the case of Quassia excelsa, we continue to adhere to it in relation to this plant. (See *Quassia.*) It is a tree of considerable height and thickness, having alternate branches, with a bark which in the old tree is black and somewhat furrowed, in the young is smooth, gray, and marked here and there with broad yellow spots. The leaves are alternate and abruptly pinnate, with a naked petiole, to which the leaflets are alternately attached by short footstalks. The leaflets are nearly elliptical, on the upper surface smooth and of a deep-green colour, on the under whitish. The flowers are yellow, and disposed in long axillary panicles. In some descriptions they are stated to be monœcious, in others dicœcious. According to Dr. Wright, the female flowers are never found in Jamaica on the same tree with the male. The number of stamens is ten.

The tree is found in the West Indies and Guyana. In Jamaica it is called the *mountain damson.* The *Simaruba amara* of Aublet, which grows in Guyana, and has generally been considered identical with *Q. simaruba*, is believed by Hayne to be a distinct species; the Jamaica plant having dicœcious, while this has monœcious flowers. The bark of the root is the part employed; the wood itself being nearly tasteless and inert.

Simaruba bark is in long pieces, some inches in breadth, folded lengthwise,

light, flexible, tenacious, very fibrous, externally of a light brownish-yellow colour, rough, warty, and marked with transverse ridges, internally of a pale yellow. It is without smell, and of a bitter taste. It readily imparts its virtues, at ordinary temperatures, to water and alcohol. The infusion is at least equally bitter with the decoction, which becomes turbid as it cools. Its constituents, according to M. Morin, are a bitter principle identical with *quassin*, a resinous matter, a volatile oil having the odour of benzoin, malic acid, gallic acid in very minute proportion, an ammoniacal salt, malate and oxalate of lime, some mineral salts, oxide of iron, silica, ulmin, and lignin.

Medical Properties and Uses. Simaruba possesses the same tonic properties as other simple bitters, and may be employed for the same purposes. In large doses it is said to purge and vomit. It was introduced into France in the year 1713 from Guyana, where it had previously been used as a remedy for dysentery. In the treatment of this disease and of obstinate diarrhœa it afterwards obtained much credit in Europe; but Cullen was right in denying to it any specific control over these complaints. It operates simply as a tonic; and, though it may be occasionally beneficial in relaxed and debilitated states of the alimentary canal, it would do much harm if indiscriminately prescribed in dysenteric cases. On account of its difficult pulverization, it is seldom given in substance. The best mode of administration is by infusion. The dose is from a scruple to a drachm.

Sinapis nigra. Willd. *Sp. Plant.* iii. 555; Woodv. *Med. Bot.* p. 403, t. 146. Common or black mustard is an annual plant, with a stem three or four feet in height, divided and subdivided into numerous spreading branches. The leaves are petiolate and variously shaped. Those near the root are large, rough, lyrate-pinnate, and unequally toothed; those higher on the stem are smooth and less lobed; and the uppermost are entire, narrow, smooth, and dependent. The flowers are small, yellow, with a coloured calyx, and stand closely together upon peduncles at the upper part of the branches. The pods are smooth, erect, nearly parallel with the branches, quadrangular, furnished with a short beak, and occupied by numerous seeds.

Sinapis alba. Willd. *Sp. Plant.* iii. 555; Smith, *Flor. Brit.* 721. The white mustard is also annual. It is rather smaller than the preceding species. The lower leaves are deeply pinnatifid, the upper sublyrate, and all irregularly toothed, rugged, with stiff hairs on both sides, and pale-green. The flowers are in racemes, with yellow petals, and linear, green, calycine leaflets. The pods are spreading, bristly, rugged, roundish, swelling in the position of the seeds, ribbed, and provided with a very long ensiform beak.

Both plants are natives of Europe and cultivated in our gardens; and *S. nigra* has become naturalized in some parts of this country. Their flowers appear in

June. The seeds are kept in the shops both whole and in the state of very fine powder, as prepared by the manufacturers for the table.

Black mustard seeds are small, globular, of a deep-brown colour, slightly rugose on the surface, and internally yellow. In the entire state they are inodorous, but have a distinct smell in powder, and when rubbed with water or vinegar exhale a strong pungent odour, sufficient in some instances to excite a flow of tears. Their taste is bitterish, hot, and pungent, but not permanent. *White mustard seeds* are much larger, of a yellowish colour, and less pungent taste. Both afford a yellow powder, which has a somewhat unctuous appearance, and cakes when compressed. This is commonly called *flour of mustard*, or simply *mustard*, and is prepared by crushing and pounding the seeds, and then sifting them; the purest flour being obtained by a second sifting. Both the black and the white seeds are used in its preparation. It is often adulterated with wheat flour coloured by turmeric, to which red pepper is added to render the mixture sufficiently hot. The skin of white mustard seeds contains a mucilaginous substance, which is extracted by boiling water. When bruised or powdered, both kinds impart their active properties wholly to water, but in a very slight degree to alcohol. They yield upon pressure a fixed oil, called *oil of mustard*, of a greenish-yellow colour, little smell, and a mild not unpleasant taste; and the portion which remains is even more pungent than the unpressed seeds. The fixed oil of mustard yields, upon saponification, a peculiar acid, for which the name of *erucic acid* has been proposed. (Darby, *Chem. Gaz.*, vii. 163, from *Liebig's Annalen.*)

It has been long known that black mustard seeds yield by distillation with water a very pungent volatile oil, containing sulphur. Guibourt conjectured, and Robiquet and Boutron proved, that this oil does not pre-exist in the seeds, but is produced by the action of water. Hence the absence or very slight degree of odour in the seeds when bruised in a dry state, and their great pungency when water is added. It seemed reasonable to suppose that the reaction in this case was similar to that exercised by water upon bitter almonds (see *Amygdala Amara*); and this has been proved to be the fact by the experiments of Simon, Bussy, Boutron, and Frémy. According to M. Bussy, there are two peculiar principles in black mustard seeds, one named by him *myronic acid*, which exists in the seeds in the state of *myronate of potassa*; the other *myrosyne*, closely analogous in character to the albuminous constituent of almonds called *emulsin*. When water is added to black mustard seed, the myrosyne, acting the part of a ferment, determines a reaction between the water and myronate of potassa, which results in the production of the volatile oil. The same thing happens when any one of the myronates is brought into contact with water and myrosyne. The presence of the last-mentioned principle is essential. Like emulsin, it becomes inoperative when coagulated by heat, alcohol, or the acids; and, if black mustard seeds be subjected to either of these agencies previously to the addition of water, they will yield no volatile oil. The myrosyne, however, sometimes partially recovers its power by continued contact with water. This substance is found also in white mustard seeds, but without the myronate of potassa. If, therefore, white mustard seeds be added to the black in which the myrosyne has been coagulated, the volatile oil will be generated on the application of water. Though closely analogous to emulsin, myrosyne is yet a distinct principle, as its place cannot be supplied by emulsin with the same effect. (*Journ. de Pharm.*, xxvi. 39.) Simon obtained results somewhat different from those of M. Bussy. The former chemist succeeded in procuring a peculiar crystalline principle from the seeds which he called *sinapisin*, and which, upon contact with water and the albuminous principle of the seeds, emitted the odour of the oil of mustard. The whole subject requires further investigation.

The *volatile oil of mustard* is usually obtained from seeds which have been deprived of their fixed oil by pressure. It is a colourless or pale-yellow liquid,

rather heavier than water, of an exceedingly pungent odour, and an acrid burning taste. It boils at about 298°; is slightly soluble in water, and readily so in alcohol and ether; with alkaline solutions yields sulphocyanurets; and consists, according to M. Löwig and Dr. Will, of nitrogen, carbon, hydrogen, and sulphur; its formula being $NC_8H_5S_2$. Dr. Will considers it a sulphocyanuret of *allyle* (C_6H_5), the compound radical of oil of garlic, which is considered a sulphuret of allyle. (*Chem. Gaz.*, No. 62 and 64.) It is the principle upon which black mustard seeds depend for their activity.

White mustard seeds do not yield volatile oil when treated with water; but an acrid fixed principle is developed, which renders these seeds applicable to the same purposes as the other variety. MM. Robiquet and Boutron, who ascertained this fact, concluded that the acrid principle resulted from the reaction of water upon *sulpho-sinapisin*, discovered in the seeds by MM. Henry, Jun., and Garot. Their reason for this belief was that mustard, which had been deprived of this ingredient, was incapable of developing the acrid principle. The myrosyne or emulsin is equally essential to the change here, as to that which occurs in black mustard; and the reaction equally fails, if this principle be previously rendered inert by heat, alcohol, or the acids. MM. Boutron and Frémy state that not only the acrid principle of white mustard, but hydrosulphocyanic acid also results from the reaction above explained; and this observation renders still closer the analogy between the changes that take place, upon contact with water, in mustard seeds and bitter almonds. (*Journ. de Pharm.*, xxvi. 50.)*

* As some may desire to push these investigations further, we give the properties of these peculiar principles, and the modes of procuring them.

Myronic acid is a fixed inodorous substance, of a bitter and sour taste, and acid reaction. When obtained separate from its bases, it forms a colourless solution, which by evaporation becomes of a thick consistence like molasses, without crystallizing. It is soluble in water and alcohol, but not in ether; and forms soluble salts with the alkalies, baryta, lime, and the oxides of lead and silver, all of which yield volatile oil of mustard, when mixed with an aqueous solution of myrosyne. It contains sulphur, besides nitrogen, carbon, hydrogen, and oxygen. It is obtained from the myronate of potassa by adding to 100 parts of that salt 38 parts of crystallized tartaric acid, concentrating the solution by evaporation, and then adding weak alcohol, which precipitates the bitartrate of potassa and retains the myronic acid in solution. To obtain *myronate of potassa* from black mustard seeds, the powder, having been dried at 212°, and deprived of its fixed oil by pressure, is treated with strong alcohol in a displacement apparatus, and, when thus nearly exhausted of everything soluble in that liquid, is pressed and treated with water. The aqueous solution is evaporated, and, before it is too much concentrated, weak alcohol is added, which precipitates a glutinous matter. The solution, being then carefully evaporated, deposits crystals of myronate of potassa, which may be obtained very pure and white by washing the mass with diluted alcohol. This salt is easily crystallizable in fine large, transparent crystals, is unalterable in the air, very soluble in water, insoluble in pure alcohol, and of a bitter taste.

Myrosyne, when dry, has the character of an albuminous substance. It is soluble in water, forming a viscid solution which froths when agitated, and is coagulated by heat, alcohol, and the acids. It is obtained by treating white mustard seed with cold water, filtering the solution, evaporating it by a heat not exceeding 100°, and, when it is of the consistence of syrup, carefully adding alcohol, which causes a precipitate easily separable by decantation. If this be dissolved in water, and the solution evaporated as before, myrosyne is obtained, though not entirely pure. (*Journ. de Pharm.*, xxvi. 39.)

The *sinapisin* of Simon is in brilliant, white, scaly crystals, sublimable by heat, soluble in alcohol, ether, and the fixed and volatile oils, but insoluble in acids and alkalies. To obtain it he exhausted black mustard seed with strong alcohol, distilled off the greater part of the alcohol, treated the residue several times with four or five times its weight of ether, from the ethereal solutions distilled off all the ether, treated the extract again with a smaller quantity of ether so as to leave behind insoluble substances, and repeated this process until the extract formed a perfectly clear solution without residue. The extract was then dissolved in cold strong alcohol, and the solution, having been decolorized with animal charcoal, was allowed to evaporate in the air. Simon obtained from 55 pounds of the seeds only 80 grains of crystallized sinapisin. (*Annal. der Pharm.*, xxviii. 291.)

Sulpho-sinapisin, the peculiar ingredient of white mustard seed, is white, crystallizable,

From the above account of the chemical relations of mustard, it is obvious that admixture with alcohol or the acids, or the application of a boiling heat, can only have the effect of impairing its medical virtues, and that the best vehicle, whether for external or internal use, is water at common temperatures.

Medical Properties and Uses. Mustard seeds swallowed whole operate as a laxative, and have acquired some reputation as a remedy in dyspepsia, and in other complaints attended with torpid bowels and deficient excitement. The white seeds are preferred, and are taken in the dose of a tablespoonful once or twice a day, mixed with molasses, or previously softened and rendered mucilaginous by immersion in hot water. They probably act in some measure by mechanically stimulating the bowels. The bruised seeds or powder, in the quantity of a large teaspoonful, operate as an emetic. Mustard in this state is applicable to cases of great torpor of stomach, especially that resulting from narcotic poisons. It rouses the gastric susceptibility, and facilitates the action of other emetics. In smaller quantities it is useful as a safe stimulant of the digestive organs; and, as it is frequently determined to the kidneys, has been beneficially employed in dropsy. Whey, made by boiling half an ounce of the bruised seeds or powder in a pint of milk and straining, is a convenient form for administration. It may be given in the dose of a wineglassful repeated several times a day. But mustard is most valuable as a rubefacient. Mixed with water in the form of a cataplasm, and applied to the skin, it very soon produces redness with a burning pain, which in less than an hour usually becomes insupportable. When a speedy impression is not desired, especially when the sinapism is applied to the extremities, the powder should be diluted with an equal portion of rye meal or wheat flour. Care should be taken not to allow the application to continue too long, as vesication with obstinate ulceration, and even sphacelus may result. This caution is particularly necessary in cases where the patient is insensible, and the degree of pain can afford no criterion of the sufficiency of the action. The volatile oil, which is powerfully rubefacient, and capable of producing speedy vesication, has been considerably used in Germany. For external application as a rubefacient, 30 drops may be dissolved in a fluidounce of alcohol, or 6 or 8 drops in a fluidrachm of almond or olive oil. It has been given internally in colic, two drops being incorporated with a six-ounce mixture, and half a fluidounce given for a dose. (See *Am. Journ. of Pharm.*, xi. 9.) In overdoses it is highly poisonous,

inodorous, bitter, and soluble in alcohol and water, forming a yellow solution. It was at first thought by MM. Henry and Garot to be an acid, but they afterwards ascertained that it was neuter. It consists of sulphur, nitrogen, carbon, hydrogen, and oxygen. It may be obtained from white mustard seeds, previously deprived of the fixed oil by expression, by boiling them in water, evaporating the decoction to the consistence of honey, mixing the residue with 6 or 8 times its volume of anhydrous alcohol which precipitates various substances, then distilling off the alcohol, and setting aside the syrupy residue to crystallize. The crystals may be purified by repeated solution and crystallization in alcohol. (Berzelius, *Traité de Chimie.*) This principle, which has also been called *sinapin*, is considered by L. von Babo and Hirschbrunn to be the sulphocyanuret of an alkaloid, to which they propose to confine the name of *sinapin*, and for which they give the formula $NC_{32}H_{26}O_{12}$. The *sulphocyanuret of sinapin* is obtained from seeds, already so far exhausted by cold alcohol as to yield only a pale-yellow colour to that liquid, by boiling them in alcohol of the sp. gr. 0·833, evaporating the liquor, and crystallizing. It has an appearance like that of crystallized sulphate of quinia, is soluble with difficulty in cold water and alcohol, but readily in both liquids when hot, and is nearly insoluble in ether. When boiled with alkalies, it yields an acid called *sinapic acid*. It is difficult to separate the organic base sinapin from it, because this is decomposed by alkalies. It does not appear that sulphocyanuret of sinapin yields with synaptase the acrid principle developed in white mustard seeds by water; but the authors state that another substance rich in sulphur has been ascertained by Simon to exist in white mustard seeds, which plays an important part in the production of the pungent matter. (See *Chem. Gaz.*, March 1, 1853, p. 81.)

producing gastro-enteric inflammation, and probably perverting the vital processes by pervading the whole system. Its odour is perceptible in the blood, and it is said to impart the smell of horseradish to the urine.

SODIUM.

Sodium.

[1] Sodium, *Fr.;* Natrium, Natronmetall, *Germ.;* Sodio, *Ital., Span.*

Sodium is a peculiar metal, forming the radical of the alkali soda. It was discovered by Sir H. Davy in 1807, who obtained it in minute quantity by decomposing the alkali by the agency of galvanic electricity. It was afterwards procured in much larger quantities by Gay-Lussac and Thenard, by bringing the alkali in contact with iron turnings heated to whiteness. The iron became oxidized, and the metallic radical of the soda was liberated. It is now obtained by the cheaper process of Schoedler, which consists in converting, by ignition, the commercial acetate of soda into carbonate and charcoal, and heating the product to whiteness in an iron mercury-bottle, mixed with an additional portion of charcoal.

Sodium is a soft, malleable, sectile solid, of a silver-white colour. It possesses the metallic lustre in a high degree when protected from the action of the air, by which it is quickly tarnished and oxidized. Its sp. gr. is 0·97, fusing point about 200°, equivalent number 23·3, and symbol Na. Its chemical affinities resemble those of potassium, but are less energetic. Like potassium it has a strong attraction for oxygen. When thrown upon cold water it instantly fuses into a globule without inflaming, and traverses the surface in different directions with rapidity; on hot water it inflames. In both cases the water is decomposed, hydrogen is liberated, and a solution of soda generated. It combines also with a larger proportion of oxygen than exists in soda, forming a *sesquioxide*. This oxide is always formed when the metal is burnt in the open air.

Sodium is an ingredient in a number of important medicinal preparations, and is briefly described in this place as an introduction to these compounds. Its protoxide only is salifiable, constituting the alkali soda, which, united to acids, gives rise to a numerous class of compounds, called salts of soda. These are characterized by their communicating to the blowpipe flame a rich yellow colour, and by not being precipitable by any reagent, except the metantimoniate of potassa. (See *page* 585.) Protoxide of sodium (dry soda) consists of one eq. of sodium 23·3, and one of oxygen 8=31·3. United with one eq. of water 9, it forms hydrate of soda (caustic soda), weighing 40·3.

The officinal combinations containing sodium are chloride of sodium, the solutions of soda and chlorinated soda, the acetate, borate, carbonate, bicarbonate, phosphate, sulphate, and valerianate of soda, and the tartrate of potassa and soda. The description of a part of these combinations will immediately follow; while the remainder will be noticed, under their respective titles, in the second part of this work. B.

SODÆ ACETAS. *U. S., Dub.*

Acetate of Soda.

Terra foliata tartari, *Lat.;* Acétate de soude, *Fr.;* Essigsaures Natron, *Germ.;* Acetato di soda, *Ital.*

Acetate of soda is included among the Preparations by the Dublin College; but, as it is obtained on a large scale by the manufacturing chemist, it is more

properly placed in the catalogue of the Materia Medica in the United States Pharmacopœia.

Preparation. The Dublin College obtains this salt by the following process. "Take of Crystallized Carbonate of Soda of commerce *one pound* [avoirdupois], or a sufficient quantity; Acetic Acid of commerce (sp. gr. 1·044) *one pint* [Imp. meas.]. To the Acid, placed in a porcelain capsule, add by degrees the Carbonate of Soda, and, taking care that there shall be a slight excess of Acid, evaporate the resulting solution till a pellicle begins to form on its surface, and set it by to crystallize. The crystals, when drained of the mother liquor, and dried by a short exposure to air on a porous brick, should be enclosed in a well stopped bottle." *Dub.*

Acetate of soda is prepared by the manufacturer of crude pyroligneous acid, for the purpose of being decomposed so as to yield the officinal acetic acid by the action of sulphuric acid. The steps of the process by which it is made from the crude acid have already been given under the head of *Acidum Aceticum*, page 18.

Properties, &c. Acetate of soda is a white salt, crystallized in long striated prisms, and possessing a sharp, bitterish, not disagreeable taste. Exposed to a dry air it effloresces slowly, and loses about forty per cent. of its weight. It is soluble in about three parts of cold water, and in twenty-four of alcohol. Subjected to heat it undergoes first the aqueous and then the igneous fusion, and is finally decomposed; the residue being a mixture of carbonate of soda and charcoal. By the affusion of sulphuric acid it is decomposed, the acetic acid being liberated, known by its acetous odour, and sulphate of soda formed. The salt should be perfectly neutral to test paper, and not precipitated by chloride of barium, nitrate of silver, or chloride of platinum. The non-action of these tests proves the absence of sulphates, chlorides, and salts of potassa. For the proper action of the nitrate of silver test, the solution should be dilute; for if it be strong, there will be a crystalline precipitate of acetate of silver, which dissolves on the addition of water. Acetate of soda consists, when crystallized, of one eq. of acetic acid 51, one of soda 31·3, and six of water 54=136·3.

Medical Properties and Uses. Acetate of soda is diuretic, and possesses generally the same medical properties as acetate of potassa, to which article the reader is referred. It is, however, more convenient for exhibition than the latter salt, as it is not deliquescent. The dose is from a scruple to two drachms. It is employed principally to yield acetic acid by the action of sulphuric acid.

B.

SODÆ BORAS. *U. S.*

Borate of Soda.

Off. Syn. BORAX. *Lond., Ed., Dub.*

Borate de soude, Borax, *Fr.;* Boraxsaures Natron, Borax, *Germ.;* Borace, *Ital.;* Borrax, *Span.;* Boorak, *Arab.*

Borax was known to the ancients, but its chemical nature was first ascertained by Geoffroy in 1732. It exists native, and may be obtained by artificial means. It occurs in several localities in Europe, in Peru, and in beds associated with borate of lime in the district of Iquique, in the Republic of Ecuador. This mineral, as analyzed by M. Le Canu, contained from 13 to 19 per cent. of borate of soda, and from 23 to 26 per cent. of borate of lime. (*Journ. de Pharm.*, July, 1853, p. 22.) It has already become an article of commerce. Borax is found abundantly in certain lakes of Thibet and Persia, from which it is obtained by spontaneous evaporation. The impure borax concretes on the margins of these lakes, and is dug up in lumps, called in commerce *tincal* or *crude borax*. In this

state it is in the form of crystalline masses, which are sometimes colourless, sometimes yellowish or greenish, and always covered with an earthy coating, greasy to the touch, and having the odour of soap. The greasy appearance is derived from a fatty matter, saponified by soda. The tincal thus obtained in the interior is transferred to the seaports of India, especially Calcutta, from which it is exported to this country in chests. Besides Indian tincal, there is another commercial variety of borax which comes from China, and which is partially refined. Both varieties require to be purified before being used in medicine or the arts.

Purification. The method of refining borax was originally possessed as a secret by the Venetians and Dutch, but is now practised in several European countries. The process pursued in France, as reported by Robiquet and Marchand, is as follows. The tincal is placed in a large wooden vessel, and covered to the depth of three or four inches with water; in which state it is allowed to remain for five or six hours, being agitated from time to time. Slaked lime is now added, in the proportion of one part to four hundred of the impure salt; and the whole, being thoroughly mixed, is allowed to remain at rest till the succeeding day. The salt is next separated by means of a sieve, the crystals being crumbled between the hands, and placed so as to drain. The object of this treatment is to separate the soapy matter, with which the lime forms an insoluble soap; and at the same time sulphate of soda and chloride of sodium are removed, with only a minute loss of the borax. The borax being drained is next dissolved, by the assistance of heat, in two and a half times its weight of water, and the solution treated with one-fiftieth of its weight of chloride of calcium, in order to complete the separation of the soapy matter; after which it is strained through a coarse bag. The liquor is then concentrated by heat, and run into wooden vessels, lined with lead, having the shape of an inverted quadrangular pyramid. If care be taken that the cooling proceeds very gradually, distinct crystals will be obtained, such as are found in commerce; otherwise, crystalline crusts will be formed. The Chinese borax is purified in a similar manner; but, being less impure than the common tincal, does not require to be washed.

Preparation of Artificial Borax. Large quantities of borax are now made by the direct combination of *native boracic acid* with soda. The acid is found in solution in certain lagoons in Tuscany, from which hot vapours are ejected, and which are situated within a space of ten or twelve miles. The water of the lagoons is economically concentrated by the hot vapours themselves. In 1846, the product of these lagoons was estimated by M. Larderel, the original manufacturer of the acid, at three millions of Tuscan pounds. As here procured, the acid contains from 17 to 20 per cent. of impurities, consisting principally of the sulphates of ammonia, magnesia, lime, and alumina, muriate of ammonia, chloride of iron, and clay, sand, and sulphur. It is added to saturation to a solution of carbonate of soda, heated by steam, and the liquor, after boiling, is allowed to stand for ten or twelve hours. It is then drawn off into wooden vessels lined with lead, where it crystallizes. The impure crystals, thus obtained, are refined by dissolving them in water heated by steam, adding carbonate of soda to the solution, and crystallizing. The merit of introducing the process for obtaining artificial borax belongs to Cartier and Payen, who succeeded in establishing its manufacture in France, notwithstanding the strong prejudice felt against the use of the artificial salt. In the process for artificial borax of M. Koehnke, a solution of caustic soda is used, extemporaneously obtained by the action of lime. For the details of his process, see the *Am. Journ. of Pharm.*, xvii. p. 111.

Properties. Borax is a white salt, generally crystallized in flattened hexahedral prisms, terminated by triangular pyramids, and possessing a sweetish, feebly alkaline taste, and an alkaline reaction. It dissolves in twelve times its

weight of cold, and twice its weight of boiling water. Exposed to the air it effloresces slowly, and the surface of the crystals becomes covered with a white powder. Subjected to a moderate heat it undergoes the aqueous fusion, swells considerably, and finally becomes a dry porous mass, with loss of half its weight. Above a red heat it melts into a limpid liquid, and, after cooling, concretes into a transparent solid, called *glass of borax*, much used as a flux in assays with the blowpipe. Borax has been found, in the English market, adulterated to the extent of twenty per cent. with phosphate of soda. The foreign salt may be detected by exposing the suspected borax to the heat of a drying room for a few hours, when the phosphate, if present, will effloresce, and may be picked out. Sulphuric acid, added to a saturated solution of the salt, unites with the soda, and precipitates the *boracic acid* in white, shining, scaly crystals, possessing the property of imparting a green colour to the flame of burning alcohol. Boracic acid consists of one eq. of boron 10·9, and three of oxygen 24=34·9.

Borax has the property of rendering cream of tartar very soluble in water, and forms a combination with it called *soluble cream of tartar*, which is sometimes used in medicine. This preparation is made by boiling six parts of cream of tartar and two of borax in sixteen of water for five minutes, allowing the solution to cool, and then filtering to separate some tartrate of lime. Soluble cream of tartar attracts moisture from the air, and is soluble in its own weight of cold, and half its weight of boiling water. A similar preparation may be made by substituting boracic acid for the borax, the proportions being four parts of cream of tartar to one of the acid. This combination is even more soluble than the other. It has not been well ascertained what is the nature of these compounds. Thenard has thrown out the suggestion, that the former consists of two double salts, tartrate of potassa and soda (Rochelle salt), and tartrate of potassa and boracic acid, the boracic acid acting the part of a base; and Berzelius inclines to the opinion that the latter is a double tartrate of potassa and boracic acid. According to the formula of the Paris Codex, soluble cream of tartar is made with boracic acid. Four hundred parts of cream of tartar and one hundred of the acid are dissolved in a silver basin, at the temperature of ebullition, in 2400 parts of water. The solution is kept boiling until the greater part of the water is consumed. The fire is then moderated, and the solution continually stirred while the evaporation proceeds. When the matter has become very thick, it is removed by portions, which are flattened in the hand, completely dried by the heat of a stove, reduced to powder, and kept in well stopped bottles.

Composition. Borax consists of two eqs. of boracic acid 69·8, and one of soda 31·3=101·1. It ordinarily crystallizes in prisms, and contains ten eqs. of water (*prismatic borax*); but a variety of the salt exists, which crystallizes in octohedrons, and contains only five eqs. of water (*octohedral borax*). The latter is obtained in the artificial production of borax, by crystallizing from a concentrated solution at a temperature between 174° and 133°. When a solution of borax is evaporated at 212°, the salt is left as an amorphous, transparent, brittle mass, containing four eqs. of water. (*Schweitzer.*) From the composition of borax in equivalents, it is evidently a *biborate*, though sometimes called a subborate on account of its possessing an alkaline reaction.

Medical Properties and Uses. Borax is a mild refrigerant and diuretic. It is supposed also to exercise a specific influence over the uterus, promoting menstruation, facilitating parturition, and favouring the expulsion of the placenta. (Vogt's *Pharmakodynamik*, cited by Pereira.) Dr. Binswanger, in a prize essay published in 1848, denies its specific power of exciting uterine contractions, or promoting menstruation. Nevertheless Dr. Daniel Stahl, of Indiana, found it useful in dysmenorrhœa, occurring in sanguineous constitutions, venesection being premised. He gives it in doses of about nine grains every two

hours in a tablespoonful of flaxseed tea, for two days before the time of the expected return of the menses. (See *Am. Journ. of Med. Sci.*, xx. 536.) Virey deemed it aphrodisiac; and, according to Dr. J. C. Hubbard, it is eminently so, when used in the form of enema. (*New York Journ. of Med.*, for Nov. 1848, from the *Annalist.*) Binswanger considers borax as the best remedy that can be used in nephritic and calculous complaints, dependent on an excess of uric acid. It probably acts in such cases as an alkali, the soda of the salt neutralizing the uric acid, occurring in the urinary passages, and the boracic acid being set free. The dose is from thirty to forty grains. Cream of tartar, rendered soluble by borax or boracic acid, is a convenient preparation, where it is desirable to administer large quantities of the former salt. Externally the solution of borax is used as a wash in scaly cutaneous eruptions. A solution formed by dissolving a drachm of the salt in two fluidounces of distilled vinegar has been found, both by Dr. Abercrombie and Dr. Christison, an excellent lotion for ringworm of the scalp. Borax is very much used as a detergent in aphthous affections of the mouth in children. When employed for this purpose, it is generally applied in powder, either mixed with sugar in the proportion of one part to seven, or rubbed up with honey. (See *Mel Boracis.*)

Off. Prep. Mel Boracis. B.

SODÆ CARBONAS. *U. S., Lond., Ed.*

Carbonate of Soda.

Off. Syn. SODÆ CARBONAS CRYSTALLIZATUM. *Dub.*

Carbonate de soude, *Fr.;* Einfach Kohlensaures Natron, *Germ.;* Carbonato di soda, *Ital.;* Carbonato de soda, *Span.*

In the U. S. Pharmacopœia this salt has been always placed in the list of the Materia Medica; the crystallized carbonate of soda, obtained on a large scale by the manufacturing chemist, being a nearly pure salt, and that which is sold in the shops of our apothecaries. The same position is now given to it by the three British Colleges; the officinal processes for preparing it having been abandoned by the Edinburgh College in 1839, and by the Dublin and London Colleges in their recent Pharmacopœias of 1850 and 1851.

Before entering upon the consideration of the carbonate of soda as a pure salt, we shall speak generally of the sources of the alkali soda.

The sources of carbonated soda may be divided into the natural and artificial. The natural sources are the minerals of native soda, and certain marine plants which yield the alkali in their ashes; the artificial are certain salts which furnish it by chemical decomposition.

Native soda, sometimes called *natron*, is found chiefly in Hungary, Egypt, and South America, and exists, in these countries, either in the earth of the surface, which often exhibits a saline efflorescence, or in solution in small lakes, from which it is extracted by taking advantage of the drying up of the water during the heats of summer. That from Egypt, called *trona* by the natives, is a *sesquicarbonate;* while that from South America is less carbonated. Native soda, in the form of a sesquicarbonate, has been found in a soda lake in the territory of the Nizam, India. (See *Am. Journ. of Pharm.*, July, 1853, p. 350.)

Impure soda, derived from the ashes of plants growing on the surface or borders of the sea, is called barilla or kelp, according to the character of the plants incinerated. Barilla is obtained from several vegetables, principally belonging to the genera *Salsola*, *Salicornia*, and *Chenopodium*. In Spain, Sicily, and some other countries, the plants are regularly cultivated for the purpose of yielding soda by their combustion. When ripe, they are cut down,

dried, and burnt in heaps. The ashes form a semi-fused, hard, and compact saline mass, which is broken up into fragments by means of pickaxes, and thrown into commerce. Kelp, called *vareck* in France, is procured by the incineration of various kinds of sea-weeds, principally the algæ and fuci, which grow on the rocky coasts of many countries. The Orkneys and Hebrides, and the rocky coasts of Wales, Scotland, and Ireland, furnish large quantities of these weeds. The plants are allowed to ferment in heaps, then dried, and afterwards burnt to ashes in ovens, roughly made with brick or stone, and built in the ground. The alkali in the ashes melts, and forms the whole into one solid mass. When cold, it is broken up with iron instruments into large heavy masses, in which state it is found in commerce. About twenty-four tons of sea-weeds are required to produce one of kelp.

Barilla, when of good quality, is in hard, dry, porous, sonorous, grayish-blue masses, which become covered with a saline efflorescence after exposure to the air. It possesses an alkaline taste and peculiar odour. *Spanish barilla* contains from twenty-five to forty per cent. of real carbonated alkali; the residue being made up of sulphate of soda, sulphuret and chloride of sodium, carbonate of lime, alumina, silica, oxidized iron, and a small portion of charcoal which has escaped combustion. Before the introduction of artificial soda, barilla formed the source of the crystallized carbonate employed in medicine. At present barilla is principally used in the manufacture of soap.

Kelp is in hard, vesicular masses, of a dark-gray, bluish, or greenish colour, sulphurous odour, and acrid, caustic taste. It is still less pure than barilla, containing only from five to eight per cent. of carbonated soda; the rest being made up of a large proportion of the sulphates of soda and potassa, and the chlorides of potassium and sodium, a small quantity of iodide of sodium, and insoluble and colouring matters. Large quantities of kelp were formerly manufactured in Great Britain and the neighbouring islands, particularly the Orkney Islands; but the demand and production have greatly fallen off, since the introduction of artificial soda at a comparatively low price. At present kelp is used principally in the manufacture of iodine. (See *Iodinium.*)

Artificial Soda. Several plans have been proposed for obtaining soda by chemical decomposition; but none are at present used, except that of decomposing sulphate of soda. This salt is procured from the manufacturers of chlorinated lime (bleaching powder), or, what is more usual on account of the insufficient supply from that source, is made expressly for the purpose, by decomposing common salt (chloride of sodium) by sulphuric acid. The dried sulphate is mixed with its own weight of ground limestone, and half its weight of small coal, ground and sifted, and the whole is heated in a reverberatory furnace, where it fuses and forms a black mass, called *black ash*, *soda ball*, or *British barilla.* The coal, at the temperature employed, converts the sulphate of soda into sulphuret of sodium. This reacts with the limestone, so as to form sulphuret of calcium and carbonate of soda (NaS and $CaO,CO_2 = CaS$ and NaO,CO_2.) If this compound were digested in water, sulphuret of sodium and carbonate of lime would be reproduced. To prevent this result a large excess of lime is used, which gives rise to the formation of an oxysulphuret of calcium ($3CaS,CaO$), which is insoluble in water, and without action on carbonate of soda. British barilla contains about 36 per cent. of alkali, imperfectly carbonated on account of the high heat used; the remainder being principally oxysulphuret of calcium, caustic lime, and coaly matter. It is next digested in warm water, which takes up the alkali and other soluble matters, and leaves the insoluble impurities, called *soda waste.* The solution is evaporated to dryness, and the mass obtained is calcined with one-fourth of its weight of sawdust, in order to convert the alkali fully into carbonate, by means of the carbonic acid resulting from the

combustion of the sawdust. The product is redissolved in water, and the solution evaporated to dryness. The alkali, in this stage of its purification, contains about 50 per cent. of carbonate of soda and is called *soda-ash*. It is brought to the state of crystallized carbonate of soda by dissolving it in water, straining the solution, evaporating it to a pellicle, and setting it aside to crystallize. On the subject of the products of the soda manufacture, see the elaborate paper of John Brown, Esq , in the *Lond., Ed., and Dub. Philos. Mag.* for Jan. 1849.

The chemical process here described for obtaining carbonated soda was discovered in 1784 by Le Blanc and Dizé. It is at present pursued on an immense scale in Great Britain, especially at Liverpool and Glasgow; and its product is so cheap that its use has nearly superseded that of barilla and kelp as sources of soda.

Carbonate of soda may also be obtained by the patented process of Mr. Henry Pemberton, of Philadelphia. This consists in converting sulphate of soda into sulphuret of sodium in the usual manner, and decomposing the latter by means of a stream of carbonic acid, derived from the chimneys of furnaces in which coal or wood is used as fuel. By the aid of the elements of water, carbonate of soda is formed, and sulphuretted hydrogen disengaged. A patent for the same process was subsequently obtained, in England, by Mr. W. E. Newton (Nov. 1852). In Mr. Newton's plan, the sulphuretted hydrogen is decomposed, so as to furnish sulphur or sulphurets. (See *Am. Journ. of Pharm.*, xxvi. 46.)

The different kinds of impure carbonate of soda, whether barilla, kelp, or soda-ash, being exceedingly variable in composition, it is important to have a ready method of determining the quantity of real carbonated alkali which they contain. The mode in which this is done, by means of an instrument called an alkalimeter, has been already explained. (See *page* 584.) These various forms of carbonated soda are largely consumed in the manufacture of soap and glass, and in dyeing and bleaching.

The following are descriptions of the different grades of artificial soda, known under the names of British barilla, soda-ash, and crystallized carbonate of soda.

British barilla, so called to distinguish it from Spanish barilla, which has its source in the ashes of maritime plants, is a blackish-brown substance, becoming darker by exposure to the air. When broken it exhibits an imperfect metallic lustre, and a close striated texture. Its taste is caustic and hepatic. By exposure to a moist atmosphere, it becomes covered with a yellow efflorescence, and quickly falls to powder, with disengagement of heat and sulphuretted hydrogen; at the same time increasing in weight by the absorption of carbonic acid and water.

Soda-ash is in white or gray compact masses, and contains about half its weight of foreign salts, consisting principally of chloride of sodium and sulphate of soda.

Crystallized carbonate of soda is a colourless salt, possessing an alkaline and disagreeable taste, and crystallizing usually in large oblique rhombic prisms, which speedily effloresce and fall into powder when exposed to the air. It is soluble in twice its weight of cold water, but insoluble in alcohol, and displays an alkaline reaction with tests. When heated it undergoes the aqueous fusion; and, if the heat be continued, it dries and finally suffers the igneous fusion. The most usual impurities are sulphate of soda and common salt, which may be detected by converting the salt into a nitrate, and testing separate portions of this severally with the chloride of barium and nitrate of silver. Common salt is seldom entirely absent, but good specimens are free from sulphate of soda. When badly prepared, it is liable to contain a portion of sulphuret of sodium, which may be detected by the production of the smell of sulphuretted hydrogen upon dissolving the salt in water. Carbonate of soda is incompatible with acids, acidulous salts, lime-water, muriate of ammonia, and earthy and metallic salts. It consists of one eq. of carbonic acid 22, and one of soda 31·3=53·3. When

fully crystallized it contains ten eqs. of water 90, giving as the number representing the crystallized salt 143·3. It is thus perceived that this salt, when perfectly crystallized, contains nearly two-thirds of its weight of water; but the quantity actually present in it, as found in the shops, is variable, being dependent on the extent to which it may have undergone efflorescence.

Medical Properties and Uses. Carbonate of soda is antacid, antilithic, and resolvent. It is given principally in diseases attended with acidity of the stomach; such as gout, uric acid gravel, and certain forms of dyspepsia. It is more frequently exhibited than carbonate of potassa, as, from its less acrid taste, it is more easily taken. It has also been recommended in hooping-cough, scrofula, and bronchocele. In the latter disease, Dr. Peschier, of Geneva, considers it more efficacious than iodine. It is also employed with advantage, internally and externally, in skin diseases, especially those of a papular and scaly character. A lotion suitable for these cases may be formed by dissolving from two to three drachms of the carbonate in a pint of water. For a bath, from eight to sixteen ounces of the salt may be dissolved in the necessary quantity of water. The ointment should vary in strength from eight to sixty grains to the ounce of lard, according to the character of the affection. Carbonate of soda is given in doses of from ten grains to half a drachm, either in powder, or in solution in some bitter infusion. In consequence of the variable state in which it exists in the shops, as to the amount of water of crystallization which it contains, the dose cannot be indicated with precision. It is on this account that the salt is most conveniently administered in the dried state, which admits of its being given in the pilular form. (See *Sodæ Carbonas Exsiccatus.*) When taken in an overdose it acts as a corrosive and irritant poison. The best antidotes are fixed oils, acetic acid, and lemon juice.

Pharm. Uses. Carbonate of soda is used as a chemical agent by the Edinburgh College in preparing sulphate of quinia, and by the London College in making ammonio-citrate of iron.

SODÆ SULPHAS. *U. S., Lond., Ed., Dub.*

Sulphate of Soda.

Vitriolated soda, Glauber's salt; Sulfate de soude, *Fr.;* Schwefelsaures Natron, Glaubersalz, *Germ.;* Solfato di soda, *Ital.;* Sulfato de soda, Sal de Glaubero, *Span.*

Sulphate of soda, in small quantities, is extensively diffused in nature, and is obtained artificially in several chemical operations. It exists in solution in many mineral springs, among which may be mentioned those of Cheltenham and Carlsbad; and it is found combined with sulphate of lime, constituting a distinct mineral. Many ponds containing this salt are found in the country between Santa Fe and the head waters of the Arkansas, and on the route to the Rocky Mountains. The water in one of these ponds forms a solution so highly concentrated that, in dry weather, the salt crystallizes on the surface to the depth of several inches, so as to have the appearance of limpid ice. (*Am. Journ. of Pharm.*, xii. 110.) As an artificial product, it is formed in the processes for obtaining muriatic acid and chlorine, and in the preparation of muriate of ammonia from sulphate of ammonia and common salt. It may also be procured from sea-water, in which its ingredients are present.

Of the Pharmacopœias commented on in this work, the Edinburgh is the only one which gives a formula for preparing this salt. It is directed to be obtained from the salt, left after the distillation of muriatic acid, by the following process. Dissolve *two pounds* of the salt, which is a supersulphate of soda, in *three pints* (Imp. meas.) of boiling water. Then saturate the excess of acid with powdered white marble, and, having boiled the liquid and filtered it, wash the insoluble matter with boiling water, and add the washings to the original liquid. Lastly concentrate the solution to a pellicle, and set it aside to crystallize. In this process the excess of acid is removed by converting it into the insoluble sulphate of lime.

Immense quantities of sulphate of soda are made in Great Britain and France by the process of decomposing common salt by sulphuric acid, for the purpose of being manufactured into soda-ash and carbonate of soda; and, so far from the generated muriatic acid being a product of value, its absorption in a convenient way, so as to avoid the nuisance of its escape into the atmosphere in a gaseous state, is an object of importance to the manufacturer. (See *Acidum Muriaticum.*) MM. Thomas, Dellisse, and Boucard have proposed a new process for preparing sulphate of soda, by double decomposition between chloride of sodium and sulphate of iron. It is stated that this process furnishes the salt cheaply; and, at the same time, it avoids the production of muriatic acid vapours.

The residuum of the process for obtaining chlorine, by the action of sulphuric acid and deutoxide of manganese on common salt, is a mixture of sulphate of soda and sulphate of protoxide of manganese. (See *Chlorinii Liquor.*) Large quantities of this residuum are formed in manufacturing chlorinated lime (bleaching salt); and the sulphate of soda in it, roughly purified, supplies a part of the consumption of this salt in making soda-ash and carbonate of soda. (See *Sodæ Carbonas.*)

In the process for obtaining muriate of ammonia from sulphate of ammonia and common salt, water is decomposed, and a double decomposition takes place, resulting in the formation of sulphate of soda and muriate of ammonia. By exposing the mixed salts to heat, the muriate of ammonia sublimes, and the sulphate of soda remains behind. (See *Ammoniæ Murias.*)

In some of our Northern States, particularly Massachusetts, a portion of Glauber's salt is procured from sea-water in the winter season. The circumstances under which it is formed have been explained by Mr. Daniel B. Smith, in a paper published in the fourth volume of the *Journal of the Philadelphia College of Pharmacy.* The constituents of a number of salts exist in sea-water; and the binary order in which these constituents will precipitate during evaporation, depends on the temperature. During the prevalence of rigorous cold, sulphate of soda is the least soluble salt which can be formed out of the acids and bases present, and consequently separates in the form of crystals.

Properties. Sulphate of soda is a colourless salt, possessing a cooling, nauseous, very bitter taste, and crystallizing with great facility in six-sided striated prisms. When recently prepared, it is beautifully transparent; but by exposure to the air it effloresces, and the crystals become covered with an opaque white powder. By long exposure it undergoes complete efflorescence, and falls to powder with loss of more than half its weight. It is soluble in three times its weight of cold water, and in its own weight of boiling water, but is insoluble in alcohol. Subjected to heat, it dissolves in its water of crystallization, then dries, and afterwards, by the application of a red heat, melts, with the loss of 55½ per cent. of its weight. Occasionally it contains an excess of acid or alkali, which may be discovered by litmus or turmeric paper. The presence of common salt may be detected by sulphate of silver; that of iron by ferrocyanuret of potassium or tincture of galls. This salt is not subject to adulteration. It is incompatible with carbonate of potassa, chloride of calcium, the salts of baryta, acetate and

subacetate of lead, and with nitrate of silver if the solutions are strong. It consists of one eq. of sulphuric acid 40, one of soda 31·3, and ten of water 90=161·3.

Medical Properties and Uses. Sulphate of soda, in doses of from half an ounce to an ounce, is an efficient cathartic; in smaller doses, largely diluted, an aperient and diuretic. When in an effloresced state, the dose must be reduced one-half, on account of its having lost about one-half of its weight in water. It is much less used than formerly, having been almost entirely superseded by sulphate of magnesia, which is less disagreeable to the palate. Its nauseous taste, however, may be readily disguised by the admixture of a little lemon-juice or cream of tartar, or the addition of a few drops of sulphuric acid. It is an ingredient in the artificial Cheltenham salt. (See *Appendix.*) The only use of sulphate of soda in the arts is to make carbonate of soda, and as an ingredient in some kinds of glass. It has no officinal preparations. B.

SODII CHLORIDUM. *U. S., Lond., Dub.*

Chloride of Sodium.

Off. Syn. SODÆ MURIAS. *Ed.*

Muriate of soda, Sea salt, Common salt; Chlorure de sodium, Hydro-chlorate de soude, Sel marin, *Fr.;* Chlornatrium, Kochsalz, *Germ.;* Salt, *Dan., Swed.;* Chloruro di sodio, Sal commune, *Ital.;* Sal, *Span.*

This mineral production, so necessary to mankind, is universally distributed over the globe, and is the most abundant of the native soluble salts. Most animals have an instinctive relish for it; and from its frequent presence in the solids and fluids of the animal economy, it may be supposed to perform an important part in nutrition and assimilation.

Natural State. Common salt exists in nature, either in the solid state or in solution. In the solid state, called *rock salt*, *fossil salt*, and *sal gemmæ*, it is often found forming extensive beds, and even entire mountains, from which it is extracted in blocks or masses by mining operations. Its geological position is very constant, occurring almost invariably in secondary formations, associated with clay and gypsum. In solution it occurs in certain springs and lakes, and in the waters of the ocean. The principal salt mines are found in Poland, Hungary, and Russia; in various parts of Germany, particularly the Tyrol; in England in the county of Cheshire; in Spain; in various parts of Asia and Africa; and in Peru, and other countries of South America. In the United States there are no salt mines, but numerous salt springs, which either flow naturally, or are produced artificially by sinking shafts to various depths in places where salt is known to exist. These are found principally in Missouri, Kentucky, Illinois, Ohio, Pennsylvania, Virginia, and New York. In the last-mentioned State the springs are the most productive; the chief ones being situated at Salina, Montezuma, and Galen. In Virginia an important salt region exists, extending fifteen miles on both sides of the great Kenhawa river. Rock salt is always transparent or translucent; but it often exhibits various colours, such as red, yellow, brown, violet, blue, &c., which are supposed to be derived from iron and manganese.

Extraction. Mines of salt are worked in two ways. When the salt is pure it is merely dug out in blocks and thrown into commerce. When impure it is dissolved in water, and extracted afterwards from the solution by evaporation. When the salt is naturally in solution, the mode of extraction depends upon the strength of the brine, and the temperature of the place where it is found. When the water contains from fourteen to fifteen per cent. of salt, it is extracted by evaporation in large iron boilers. If, however, it contains only two, three, four, or five per cent., the salt is obtained in a different manner. If the climate be

warm it is procured by spontaneous evaporation, effected by the heat of the sun; if temperate, by a peculiar mode of evaporation to be mentioned presently, and the subsequent application of artificial heat.

Sea-water is a weak saline solution, containing 2·7 per cent. of common salt, which is extracted by the agency of solar heat in warm countries. Salt thus obtained is called *bay salt.* The extraction is conducted in Europe principally on the shores of the Mediterranean, the waters of which are salter than those of the open ocean. The mode in which it is performed is by letting the sea-water into shallow dikes, lined with clay, and capable, after being filled, of being shut off from the sea. In this situation the heat of the sun gradually concentrates the water, and the salt is deposited. In temperate climates, weak brines are first concentrated in buildings, called *graduation houses.* These are rough wooden structures open on the sides, ten or eleven yards high, five or six wide, and three or four hundred long, and containing an oblong pile of brushwood somewhat smaller than the building itself. The brine is pumped up into troughs full of holes, placed above the brushwood, upon which it is allowed to fall; and in its descent it becomes minutely divided. This operation, by greatly increasing the surface of the brine, promotes its evaporation; and being repeated several times, the solution is at last brought to the requisite degree of strength to permit of its final concentration in iron boilers by artificial heat. Sometimes, to save fuel, the last concentration is performed by allowing the brine to trickle down a number of vertical ropes, on the surface of which the salt is deposited in the form of a crust.

Properties. Chloride of sodium is white, without odour, and of a peculiar taste called saline. It is usually crystallized in cubes; but by hasty evaporation it often assumes the form of hollow quadrangular pyramids. When pure it undergoes no change in the air; but, when contaminated with chloride of magnesium, as not unfrequently happens, it is deliquescent. Water at 54° F. dissolves 36 per cent. of this salt, and at the boiling temperature, 40 per cent. (*Fehling.*) It is but sparingly soluble in alcohol. One hundred parts of this liquid (sp. gr. 0·815) dissolve, at the temperature of 59°, only 0·174 parts of common salt. (*R. Wagner.*) Exposed to a gradually increasing heat, it first decrepitates from the presence of interstitial moisture, next melts, and finally volatilizes in white fumes without decomposition. It is decomposed by several of the acids, particularly the sulphuric and nitric, which disengage vapours of muriatic acid; by carbonate of potassa with the assistance of heat; and by the nitrates of silver and of the protoxide of mercury.

Several varieties of common salt are distinguished in commerce; as *stoved salt, fishery salt, bay salt,* &c.; but they are characterized by the size and compactness of the grains, rather than by any difference in composition.

Composition. Common salt, in its pure state, consists of one eq. of chlorine 35·42, and one of sodium 23·3=58·72. It contains no water of crystallization. When in solution it is by some supposed to become muriate of soda, in consequence of the decomposition of water, the hydrogen and oxygen of which are alleged to convert the chlorine and sodium into muriatic acid and soda. The common salt of commerce, besides pure chloride of sodium, contains, generally speaking, insoluble matter, and usually more or less of the sulphates of lime and magnesia, and chlorides of calcium and magnesium. When pure it is not precipitated by carbonate of soda, chloride of barium, or ferrocyanuret of potassium. Chloride of calcium is generally present in very small amount; but the chloride of magnesium sometimes amounts to 28 parts in 1000. Sulphate of lime is usually present, constituting variously from 1 to 23½ parts in 1000; and sulphate of magnesia is sometimes present and sometimes absent. To separate the earths, a boiling solution of carbonate of soda must be added, as long as any precipitate is formed. The earths will fall as carbonates, and must be separated

by filtration, and the sulphate of soda and chloride of sodium, resulting from the double decomposition, will remain in solution. The sulphate of soda may then be decomposed by the cautious addition of chloride of barium, which will generate chloride of sodium and insoluble sulphate of baryta.

Medical Properties and Uses. Chloride of sodium, in small doses, acts as a stimulant tonic and anthelmintic; in larger ones as a purgative and emetic. It certainly promotes digestion, and the almost universal animal appetency for it, proves it to be a salutary stimulus in health. When taken in larger quantities than usual with food, it is useful in some forms of dyspepsia. According to the experiments of M. Plouviez, made upon himself, at intervals, during twenty-five months, a saline regimen has the effect of increasing the weight and strength of the body. He began with a teaspoonful daily, which he increased to a tablespoonful, continuing to take this dose for a period of three or four months. The regimen appeared to produce plethora. The blood, analyzed while under the full effects of the salt, was found to contain more of the globules and salts, but less of the albumen and water.

On the sudden occurrence of hæmoptysis, common salt is usefully resorted to as a styptic, in the dose of a teaspoonful, taken dry, and often proves successful in stopping the flow of blood. Externally applied in solution it is stimulant, and may be used either locally or generally. Locally, it is sometimes employed as a fomentation in sprains and bruises; and as a general external application, it forms the salt-water bath, a valuable remedy as a tonic and excitant in depraved conditions of the system, occurring especially in children, and supposed to be dependent on the scrofulous diathesis. A pound of salt dissolved in four gallons of water, forms a solution of about the strength of sea-water, and suitable for a bath. It is frequently used as an ingredient in stimulating enemata. The dose, as a tonic, is from ten grains to a drachm; as a cathartic, though seldom used for that purpose, from two drachms to half an ounce. In doses of from half an ounce to an ounce, dissolved in four or five times its weight of water, it frequently proves a prompt and efficient emetic, invigorating rather than depressing the powers of the system. As a clyster, it may be used in the amount of from one to two tablespoonfuls, dissolved in a pint of water.

The uses of common salt in domestic economy as a condiment and antiseptic are well known. In agriculture it is sometimes employed as a fertilizer, and in the arts to prepare muriate of ammonia, as also to form sulphate of soda, with a view to the conversion of the latter into carbonate of soda.

Chloride of sodium, in concentrated solution, is employed by the Edinburgh College, as a chemical agent, to prepare biniodide of mercury.

SOLIDAGO. *U. S. Secondary.*

Golden-rod.

The leaves of Solidago odora. *U. S.*

Solidago. *Sex. Syst.* Syngenesia Superflua.—*Nat. Ord.* Compositæ Asteroideæ, *De Candolle;* Asteraceæ, *Lindley.*

Gen. Ch. Calyx imbricated, scales closed. *Radical florets* about five, yellow. *Receptacle* naked, punctate. *Pappus* simple pilose. *Nuttall.*

This is a very abundant genus, including, according to Eaton's enumeration, upwards of sixty species belonging to this country. Of these *S. odora* only is officinal. *S. Virgaurea*, which is common to the United States and Europe, was

formerly directed by the Dublin College, but has been omitted. It is astringent, and has been supposed to possess lithontriptic virtues.

Solidago odora. Willd. *Sp. Plant.* iii. 2061; Bigelow, *Am. Med. Bot.* i. 187. The *sweet-scented golden-rod* has a perennial creeping-root, and a slender, erect, pubescent stem, which rises two or three feet in height. The leaves are sessile, linear-lanceolate, entire, acute, rough at the margin, elsewhere smooth, and covered with pellucid dots. The flowers are of a deep golden-yellow colour, and are arranged in a terminal, compound, panicled raceme, the branches of which spread almost horizontally, are each accompanied by a small leaf, and support the flowers on downy pedicels, which put forth from the upper side of the peduncle, and have small linear bractes at their base. The florets of the ray are ligulate, oblong, and obtuse; those of the disk, funnel-shaped, with acute segments.

The plant grows in woods and fields throughout the United States, and is in flower from August to October. The leaves, which are the officinal portion, have a fragrant odour, and a warm, aromatic, agreeable taste. These properties depend on a volatile oil, which may be separated by distillation with water. It is of a pale greenish-yellow colour, and lighter than water.

Medical Properties and Uses. Golden-rod is aromatic, moderately stimulant and carminative, and, like other substances of the same class, diaphoretic when given in warm infusion. It may be used to relieve pain arising from flatulence, to allay nausea, and to cover the taste or correct the operation of unpleasant or irritating medicines. For these purposes it may be given in infusion. The volatile oil dissolved in alcohol is employed in the Eastern States. According to Pursh, the dried flowers are used as a pleasant and wholesome substitute for common tea. W.

SPIGELIA. *U. S., Ed.*

Pinkroot.

The root of Spigelia Marilandica. *U. S., Ed.*

Spigélie du Maryland, *Fr.;* Spigelie, *Germ.;* Spigelia, *Ital.*

Spigelia. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Gentianæ, *Juss.;* Spigeliaceæ, *Martius, Lindley.*

Gen. Ch. Calyx five-parted. *Corolla* funnel-shaped, border five-cleft, equal. *Capsule* didymous, two-celled, four-valved, many-seeded. *Nuttall.*

Two species of Spigelia have attracted attention as anthelmintics, *S. Anthelmia* of South America and the West Indies, and *S. Marilandica* of this country. The former is an annual plant, used only in the countries where it grows, the latter is much employed, both in this country and in Europe.

Spigelia Marilandica. Willd. *Sp. Plant.* i. 825; Bigelow, *Am. Med. Bot.* i. 142; Barton, *Med. Bot.* ii. 75. The *Carolina pink* is an herbaceous plant with a perennial root, which sends off numerous fibrous branches. The stems, several of which rise from the same root, are simple, erect, four-sided, nearly smooth, and from twelve to twenty inches high. The leaves are opposite, sessile, ovate-lanceolate, acuminate, entire, and smooth, with the veins and margins slightly pubescent. Each stem terminates in a spike, which leans to one side, and supports from four to twelve flowers with very short peduncles. The calyx is persistent, with five long, subulate, slightly serrate leaves, reflexed in the ripe fruit. The corolla is funnel-shaped, and much longer than the calyx, with the tube inflated in the middle, and the border divided into five acute, spreading segments. It is of a rich carmine colour externally, becoming paler at the base, and orange-yellow within. The edges of the segments are slightly tinged with green. The stamens, though apparently very short, and inserted into the upper part of the

tube between the segments, may be traced down its internal surface to the base. The anthers are oblong, heart-shaped; the germ superior, ovate; the style about the length of the corolla, and terminating in a linear fringed stigma, projecting considerably beyond it. The capsule is double, consisting of two cohering, globular, one-celled portions, and containing many seeds.

The plant is a native of our Southern and South-western States, being seldom if ever found north of the Potomac. It grows in rich soils on the borders of woods, and flowers from May to July. The root is the only part recognised in the Pharmacopœias. The drug was formerly collected in Georgia and the neighbouring States by the Creek and Cherokee Indians, who disposed of it to the white traders. The whole plant was gathered and dried, and came to us in bales or casks. After the emigration of the Indians, the supply of spigelia from this source very much diminished, and has now nearly if not entirely failed. The consequence was for a time a great scarcity and increase in the price of the drug; but a new source of supply was opened from the Western and South-western States, and it is now again plentiful. As we receive spigelia at present, it consists chiefly if not exclusively of the root, without the stem and leaves. We have been informed that most of it comes in casks or bales from St. Louis by the way of New Orleans. That contained in casks is to be preferred, as less liable to be damp and mouldy.

Properties. Pinkroot consists of numerous slender, branching, crooked, wrinkled fibres, from three to six inches long, attached to a knotty head or caudex, which exhibits traces of the stems of former years. It is of a brownish or yellowish-brown colour externally, of a faint, peculiar smell, and a sweetish, slightly bitter, not very disagreeable taste. Its virtues are extracted by boiling water. The root, analyzed by M. Feneulle, yielded a fixed and volatile oil, a small quantity of resin, a bitter substance supposed to be the active principle, a mucilaginous saccharine matter, albumen, gallic acid, the malates of potassa and lime, &c., and woody fibre. The principle upon which the virtues of the root are thought to depend, is brown, of a bitter nauseous taste, like that of the purgative matter of the leguminous plants, and, when taken internally, produces vertigo and a kind of intoxication.

The stalks of the dried plant are oval below the first pair of leaves, and then become obscurely four-sided. The leaves, when good, have a fresh greenish colour, and an odour somewhat like that of tea. In taste they resemble the root, and afforded to M. Feneulle nearly the same principles. The quantity, however, of the bitter substance was less, corresponding with their inferior efficacy. This circumstance should cause their rejection from the shops; as the inequality in power of the two portions of the plant would lead to uncertainty in the result, when they are both employed.

The roots are sometimes mixed with those of other plants, particularly of a small vine which twines round the stem of the Spigelia. These are long, slender, crooked, yellowish, thickly set with short capillary fibres, and much smaller and lighter-coloured than the pinkroot. They should be separated before the latter is used. The activity of spigelia is somewhat diminished by time.

Medical Properties and Uses. Pinkroot is generally considered among the most powerful anthelmintics. In the ordinary dose it usually produces little sensible effect on the system; more largely given it acts as a cathartic, though unequal and uncertain in its operation; in overdoses it excites the circulation, and determines to the brain, giving rise to vertigo, dimness of vision, dilated pupils, spasms of the facial muscles, and sometimes even to general convulsions. Spasmodic movements of the eyelids have been observed among the most common attendants of its narcotic action. The death of two children, who expired in convulsions, was attributed by Dr. Chalmers to the influence of spigelia. The

narcotic effects are said to be less apt to occur when the medicine purges, and to be altogether obviated by combining it with cathartics. The danger from its employment cannot be great; as it is in very general use in the United States, both in regular and domestic practice, and we never hear at present of serious consequences. Its effects upon the nervous system have been erroneously conjectured to depend on other roots sometimes mixed with the genuine. The vermifuge properties of spigelia were first learned from the Cherokee Indians. They were made known to the medical profession by Drs. Lining, Garden, and Chalmers, of South Carolina. The remedy has also been recommended in infantile remittents and other febrile diseases; but is entitled to little confidence in these complaints.

It may be given in substance or infusion. The dose of the powdered root for a child three or four years old, is from ten to twenty grains, for an adult from one to two drachms, to be repeated morning and evening for several days successively, and then followed by a brisk cathartic. The practice of preceding its use by an emetic has been generally abandoned. It is frequently given in combination with calomel. The infusion, however, is a more common form of administration. (See *Infusum Spigeliæ.*) It is usually combined with senna or some other cathartic, to ensure its action on the bowels. A preparation generally kept in the shops and much prescribed by physicians, under the name of *worm tea*, consists of pinkroot, senna, manna, and savine, mixed together, in various proportions, to suit the views of different individuals. Spigelia is also very often given in the form of fluid extract.

Off. Prep. Extractum Spigeliæ et Sennæ Fluidum; Infusum Spigeliæ.

W.

SPIRÆA. *U. S. Secondary.*

Hardhack.

The root of Spiræa tomentosa. *U. S.*

Spiræa. *Sex Syst.* Icosandria Pentagynia.—*Nat. Ord.* Rosaceæ.

Gen. Ch. Calyx spreading, five-cleft, inferior. *Petals* five, equal, roundish. *Stamens* numerous, exserted. *Capsules* three to twelve, internally bivalve, each one to three-seeded. *Nuttall.*

Spiræa ulmaria, queen of the meadow, or *meadow-sweet*, which is a European plant, though introduced into this country, has been found by M. Tessier, of Lyons, to possess valuable diuretic properties, united with those of a moderate tonic and astringent. All parts of it are active. M. Tessier employed it in the form of decoction, of which he gave a quart daily. See, for more extended observations in relation to this medicine, Bouchardat's *Annuaire de Thérapeutique* (A. D. 1852, p. 119).

Spiræa tomentosa. Willd. *Sp. Plant.* ii. 1056; Rafinesque, *Med. Flor.* vol. ii. This is an indigenous shrub, two or three feet high, with numerous simple, erect, round, downy, and purplish stems, furnished with alternate leaves closely set upon very short footstalks. The leaves are ovate-lanceolate, unequally serrate, somewhat pointed at both ends, dark-green on their upper surface, whitish and tomentose beneath. The flowers are beautifully red or purple, and disposed in terminal, compound, crowded spikes or racemes.

The hardhack flourishes in low grounds, from New England to Carolina, but is most abundant in the Northern States. It flowers in July and August. All parts of it are medicinal. The root, though designated in the Pharmacopœia, is, according to Dr. A. W Ives, the least valuable portion. The taste of the plant is bitter and powerfully astringent. Among its constituents are tannin, gallic acid, and bitter extractive. Water extracts its sensible properties and medicinal virtues.

Medical Properties and Uses. Spiræa is tonic and astringent, and may be used in diarrhœa, cholera infantum, and other complaints in which astringents are indicated. In consequence of its tonic powers it is peculiarly adapted to cases of debility; and, from the same cause, should not be given during the existence of inflammatory action, or febrile excitement. It is said to have been employed by the aborigines of our country; but was first brought to the notice of the medical profession by Dr. Cogswell, of Hartford, Connecticut. It is said to be less apt to disagree with the stomach than most other astringents.

The form in which it is best administered is that of an extract, prepared by evaporating the decoction of the leaves, stems, or root, or an infusion of the same parts made by percolation. The dose is from five to fifteen grains, repeated several times a day. A decoction, prepared by boiling an ounce of the plant in a pint of water, may be given in the dose of one or two fluidounces. W.

SPIRITUS PYROXILICUS. *Dub.*

Pyroxylic Spirit.

Pyroligneous spirit, Wood spirit, Pyroligneous ether, Wood naphtha, Pyroxylic alcohol, Wood alcohol, Methylic alcohol, Hydrated oxide of methyle, Bihydrate of methylene; Esprit pyroxylique, Esprit de bois, Alcool méthylique, *Fr.*

This substance was discovered in 1812 by P. Taylor, and was afterwards examined by Macaire and Marcet, Liebig, Dumas and Peligot, Kane, and others.

When wood is subjected to destructive distillation, there is formed, besides acetic acid, tar, and other products (see *page* 18), about one per cent. of an inflammable, volatile liquid, which, when separated and purified, constitutes pyroxylic spirit. The crude liquor, derived from the wood, separates on standing into two liquids; the lighter containing the tarry matters, and the heavier consisting of water, acetic acid, pyroxylic spirit, &c. The heavier liquid is saturated with lime, and subjected to distillation, whereby the impure pyroxylic spirit first comes over, mixed, however, with various compounds, among which are aldehyd and pyroacetic spirit (acetone). This, after having been redistilled, and deprived of water by repeated rectifications from lime, forms the *pyroxylic spirit of commerce.* The spirit of commerce is purified by adding to it as much chloride of calcium as it can dissolve, and allowing the mixture to stand for a few days. The pyroxylic spirit unites with the chloride of calcium, and the compound formed is subjected to distillation to separate certain contaminating substances, which distil over. Finally, the pyroxylic spirit is separated from the chloride of calcium by the addition of water and a new distillation, and from water by rectification from dry lime.

Properties. Pure anhydrous pyroxylic spirit is a mobile, colourless liquid, having a hot and pungent taste, and a peculiar aromatic smell, recalling that of acetic ether. It mixes in all proportions with water, alcohol, and ether, without having its transparency disturbed. It burns like alcohol, but with a less luminous flame. Its sp. gr. as a liquid is 0·798; as a vapour, 1·041. (*Regnault.*) It boils at 140°, and during ebullition its vapour causes concussions, which render its distillation difficult, and which may be prevented by placing in the bottom of the vessel a layer of mercury. It forms a set of compounds precisely analogous to those of the alcohol series; and from this circumstance, and from its being supposed to contain a compound radical called *methyle* (C_2H_3), it is called *methylic alcohol.* As a solvent it resembles alcohol, all bodies soluble in that menstruum being likewise soluble in pyroxylic spirit. It consists of two eqs. of carbon 12, four of hydrogen 4, and two of oxygen 16=32; and its empirical formula is $C_2H_4O_2$. Considered as a hydrated oxide of methyle, its formula is C_2H_3O+HO. Viewed as a bihydrate of methylene, it is represented by C_2H_2+2HO. Accord-

ing to Mr. Reuben Phillips, pyroxylic spirit usually contains sulphur, not easily separated from it. (*Chem. Gaz.*, July 1, 1852, p. 252.)

The officinal pyroxylic spirit is directed by the Dublin College to have the sp. gr. 0·846. The density, thus recognised, shows that the College contemplated, not the pure, but the commercial pyroxylic spirit, which has a straw-yellow colour, and a powerful odour of wood-smoke. But the commercial spirit is often too impure for medicinal use. According to Mr. Morson, of London, it may be purified "by largely diluting it with water, when an oily substance separates, after the removal of which the spirit may be recovered by distillation." Pyroxylic spirit has been confounded with pyroacetic spirit. They may be distinguished, according to Mr. Scanlan, by chloride of calcium, which is without action on the latter, but dissolves in the former. In applying the test, a drop or two of a *saturated* solution of chloride of calcium is added to the doubtful liquid in a test tube. This solution is immiscible with pyroacetic spirit, separating after agitation, but dissolves instantly in pyroxylic spirit. The liquid examined must be sufficiently pure not to separate into two layers, nor to become milky on the addition of water. (*Pharm. Journ. and Trans.* April, 1850.)

Medical Properties, &c. Pyroxylic spirit, under the incorrect name of naphtha, was introduced as a therapeutic agent, some years ago, by Dr. John Hastings, who proposed it as a remedy for pulmonary consumption. It exerts no curative power over this disease, but may be usefully employed to palliate the cough and lessen the febrile excitement which attend it. The therapeutic properties of pyroxylic spirit have not as yet been fully investigated; but so far as observation has gone, it may be ranked as a narcotic, sedative, and anti-emetic. As an anti-emetic remedy in chronic vomiting, whether dependent on functional or organic disease, Dr. Christison has found it useful, having frequently seen the vomiting arrested or greatly mitigated by its use. Dr. D. W. Yandell speaks favourably of its efficacy as a remedy in diarrhœa and dysentery. The dose is from ten to forty drops, three times a day, sufficiently diluted with water. At one time it was doubtful whether the substance, used by Dr. Hastings under the name of naphtha, was pyroxylic or pyroacetic spirit; but it is now decided to have been the former, both by the admission of Dr. Hastings, and by a careful examination of the medicinal agent currently employed.

Crude pyroxylic spirit, varying in density from 0·846 to 0·890, is employed by hatters and varnish-makers for dissolving resinous substances, and by chemists for burning in lamps as a substitute for alcohol. B.

SPIRITUS VINI GALLICI. *U. S., Lond.*

Brandy.

Eau de vie, *Fr.;* Brantwein, *Germ.;* Acquavite, *Ital.;* Aqua ardiente, *Span.*

All liquids which have undergone the alcoholic fermentation, yield an ardent spirit by distillation. (See *Alcohol*, page 60.) When the alcoholic liquid is wine, the product of the distillation is brandy. This ardent spirit is subject to variation, according to the character of the wine from which it is distilled. The most esteemed French brandies are those of Cognac and Armagnac.

Brandy has an agreeable, vinous, aromatic odour, and a peculiar, well known taste. Its sp. gr. varies from 0·902 to 0·941, and it contains on an average about 53 per cent. by measure of alcohol of the density 0·825. Besides alcohol, water, and volatile oil, it contains colouring matter, tannin, œnanthic ether described under *wine*, and a little acetic ether. Brandy is distinguished by its colour into the pale and high-coloured. *Pale brandy* has a yellow colour,

derived from the cask in which it is kept. *High-coloured* brandy has its deep-red colour given to it, before importation, by burnt sugar (caramel), which is said to impart a more agreeable flavour. *Factitious brandy* is sometimes made by adding acetic ether to alcohol, deprived of fusel oil, and reduced to the proper proof by water, in the proportion of one or two drachms to the quart. The proper colour is then given to the mixture by burnt sugar. The spurious liquid may be known by its leaving on evaporation a residue, containing sugar and no tannin; the absence of the latter being shown by its not striking a black colour with the salts of sesquioxide of iron.

Medical Properties. Brandy is esteemed cordial and stomachic, and is frequently given, in the form of toddy or milk punch, in the sinking stages of low fevers. The only officinal preparation of it is the *Mistura Spiritûs Vini Gallici* of the London College, which is an imitation of the compound known under the name of *egg-flip*.

Off. Prep. Mistura Spiritûs Vini Gallici. B.

SPONGIA. *U. S., Ed.*

Sponge.

Spongia officinalis. *U. S., Ed.*

Eponge, *Fr.;* Badeschwamm, *Germ.;* Spugna, *Ital.;* Esponja, *Span.;* Isfung, *Arab.*

The sponge is now generally admitted to be an animal. It is characterized as "a flexile, fixed, torpid, polymorphous animal, composed either of reticulate fibres, or masses of small spires interwoven together, and clothed with a gelatinous flesh full of small mouths on its surface, by which it absorbs and ejects water." More than two hundred and fifty species have been described by naturalists, of which several are probably employed, though *Spongia officinalis* is the only one designated in the Pharmacopœias. Sponges inhabit the bottom of the sea, where they are fixed to rocks or other solid bodies; and are most abundant within the tropics. They are collected chiefly in the Mediterranean and Red Seas, and in those of the East and West Indies. In the Grecian Archipelago many persons derive their support altogether from diving for sponges. When collected they are enveloped in a gelatinous coating, which forms part of the animal, and is separated by first rubbing them with fine sand (*Lunderer*), and then washing them with water. Large quantities of the coarser kinds are imported from the Bahamas; but the finest and most esteemed are brought from the Mediterranean.

Sponge, as found in commerce, is in yellowish-brown masses of various shape and size, light, porous, elastic, and composed of fine, flexible, tenacious fibres, interwoven in the form of cells and meshes. It usually contains numerous minute fragments of coral or stone, or small shells, from which it must be freed before it can be used for ordinary purposes. Sponge is prepared by macerating it for several days in cold water, beating it in order to break up the concretions which it contains, and dissolving what cannot thus be separated of the calcareous matter by muriatic acid diluted with thirty parts of water. By this process, it is rendered perfectly soft, and fit for surgical use. It may be bleached by steeping it in water impregnated with sulphurous acid, or by exposure in a moist state to the action of chlorine. When intended for surgical purposes, the softest, finest, and most elastic sponges should be selected; for forming *burnt sponge*, the coarser will answer equally well.

According to Mr. Hatchett, the chemical constituents of sponge are gelatin, coagulated albumen, common salt, and carbonate of lime. Magnesia, silica, iron, sulphur, and phosphorus have been detected in it; as also have iodine and bromine,

combined with sodium and potassium. From the experiments of Mr. Croockewit, it would appear that sponge is closely analogous to, if not identical with the fibroïn of Mulder, differing from it only in containing iodine, sulphur, and phosphorus. (*Annal. der Chem. und Pharm.*, xlviii. 43.) *Fibroïn* is an animal principle found by Mulder in the interior of the fibres of silk.

Medical Properties and Uses. Sponge, in its unaltered state, is not employed as a medicine; but, in consequence of its softness, porosity, and property of imbibing liquids, it is very useful in surgical operations. From the same qualities it may be advantageously applied over certain ulcers, the irritating sanies from which it removes by absorption. Compressed upon a bleeding vessel, it is sometimes useful for promoting the coagulation of the blood, especially in hemorrhage from the nostrils. In the shape of *sponge tent* it is also useful for dilating sinuses. This is prepared by dipping sponge into melted wax, compressing it between two flat surfaces till the wax hardens, and then cutting it into pieces of a proper form and size. By the heat of the body the wax becomes soft, and the sponge, expanding by the imbibition of moisture, gradually dilates the wound or sinus in which it may be placed. After having been partially charred by heat, sponge has long been used as a remedy in goitre. (See *Spongia Usta.*) Its efficacy in this complaint, formerly considered doubtful by many physicians, has been generally admitted since the discovery of iodine.

STANNUM. *U. S., Ed., Dub.*

Tin.

Etain, *Fr.;* Zinn, *Germ.;* Stagno, *Ital.;* Estanno, *Span.*

Tin is one of those metals which have been known from the earliest ages. It exists generally as an oxide (*tin stone* and *wood tin*), rarely as a sulphuret (*tin pyrites*), and is by no means generally diffused. It is found in England, Spain, Germany, Bohemia, and Hungary, in Europe; in the island of Banca and the peninsula of Malacca in Asia; and in Chili and Mexico. Tin mines are particularly abundant and rich in the Tenasserim provinces of British India. (*Dr. Royle.*) A valuable tin ore has been discovered in the United States, at Jackson, New Hampshire. The Cornwall mines are the most productive, but those of Asia furnish the purest tin. The metal is extracted from the native oxide. When this occurs in its purest state, in detached roundish grains, called *stream tin*, the reduction is effected by heating with charcoal. When the oxide called *mine tin*, is extracted from mines, it requires to be freed, by pounding and washing, from the adhering gangue; after which it is roasted to drive off sulphur, arsenic, and antimony, and finally reduced in furnaces by means of stone coal. The metal, as thus obtained, is not pure. To render it so, it requires to be subjected to a gentle heat, whereby the pure tin enters first into fusion, and is thus separated from the impurities, which consist of tin united with copper, arsenic, iron, and antimony. The pure metal, thus obtained, is called *grain tin;* while the impure residue, after being fused, constitutes *block-tin.*

Properties. Tin is a malleable, rather soft metal, of a silver-white colour. It may be beaten out into thin leaves, called *tin-foil.* It undergoes a superficial tarnish in the air. Its taste is slight, and when rubbed it exhales a peculiar smell. Its ductility and tenacity are small; and, when bent to and fro, it emits a crackling noise, which is characteristic of this metal. Its sp. gr. is 7·29, melting point 442°, equivalent number 58·9, and symbol Sn. It forms three oxides, a protoxide, sesquioxide, and deutoxide. The *protoxide* is of a grayish-black colour, and consists of one eq. of tin 58·9, and one of oxygen 8=66·9. When

perfectly pure it has, according to Dr. Roth, a red colour. The *sesquioxide* is gray, and is composed of two eqs. of tin 117·8, and three of oxygen 24=141·8. The *deutoxide* (*stannic acid*) is of a white colour, and constitutes the native oxide. It consists of one eq. of tin 58·9, and two of oxygen 16=74·9.

The tin of commerce is often impure, being contaminated with other metals introduced by fraud, or present in consequence of the mode of extraction from the ore. A high specific gravity is an indication of impurity. When its colour has a bluish or grayish cast, the presence of copper, lead, iron, or antimony may be suspected. Arsenic renders it whiter, but at the same time harder; and lead, copper, and iron cause it to become brittle. Pure tin is converted by nitric acid into a white powder (*deutoxide*), without being dissolved. Boiled with muriatic acid, it forms a solution which gives a white precipitate with ferrocyanuret of potassium. A blue precipitate with this test indicates iron; a brown one, copper; and a violet-blue one, both iron and copper. If lead be present, a precipitate will be produced by sulphate of magnesia. The Malacca and Banca tin, and the English grain tin are the purest kinds found in commerce. Banca tin, from recent analyses by Mulder, is particularly pure, containing only $\frac{1}{2}\frac{1}{5}$th of one per cent. of foreign metals. Block tin and the metal obtained from Germany are always of inferior quality.

Uses. Tin enters into the composition of bronze, bell-metal, pewter, and plumbers' solder. It is used also in making tin-plate, which is sheet-iron coated with tin, in silvering looking-glasses, and in forming the solution of bichloride of tin, a combination essential to the perfection of the scarlet dye. It is employed in fabricating various vessels and instruments, useful in domestic economy and the arts. Being unaffected by weak acids, it forms a good material for vessels intended for boiling operations in pharmacy. For its medical properties, see *Stanni Pulvis.*

Off. Prep. Stanni Pulvis. B.

STAPHISAGRIA. *Lond., Ed.*

Stavesacre.

Delphinium Staphisagria. The seed. *Lond., Ed.*

Staphisaigre, *Fr.;* Stephanskraut, Läusekraut, *Germ.;* Stafisagria, *Ital.;* Abarraz, *Span.*

DELPHINIUM. See DELPHINIUM.

Delphinium Staphisagria. Willd. *Sp. Plant.* ii. 1231; Woodv. *Med. Bot.* p. 471, t. 168. Stavesacre is a handsome annual or biennial plant, one or two feet high, with a simple, erect, downy stem, and palmate, five or seven-lobed leaves, supported on hairy footstalks. The flowers are bluish or purple, in terminal racemes, with pedicels twice as long as the flower, and bracteoles inserted at the base of the pedicel. The nectary is four-leaved and shorter than the petals, which are five in number, the uppermost projected backward so as to form a spur, which encloses two spurs of the upper leaflets of the nectary. The seeds are contained in straight, oblong capsules. The plant is a native of the South of Europe.

Properties. Stavesacre seeds are about as large as a grain of wheat, irregularly triangular, wrinkled, externally brown, internally whitish and oily. They have a slight but disagreeable odour, and an extremely acrid, bitter, hot, nauseous taste. Their virtues are extracted by water and alcohol. Analyzed by MM. Lassaigne and Feneulle, they yielded a brown and a yellow bitter principle, a volatile oil, a fixed oil, albumen, an azotized substance, a mucilaginous saccharine matter, mineral salts, and a peculiar organic alkali called *delphine* or *delphinia*, which exists in the seeds combined with an excess of malic acid. It is white,

pulverulent, inodorous, of a bitter acrid taste, fusible by heat and becoming hard and brittle upon cooling, slightly soluble in cold water, very soluble in alcohol and ether, and capable of forming salts with the acids. It is obtained by boiling a decoction of the seeds with magnesia, collecting the precipitate, and treating it with alcohol, which dissolves the *delphinia*, and yields it upon evaporation. According to M. Couerbe, it is impure as thus obtained, consisting of three distinct principles—one of a resinous nature separated from its solution in diluted sulphuric acid by the addition of nitric acid, another distinguished by its insolubility in ether, and named by M. Couerbe *staphisain*, and the third soluble both in alcohol and ether, and considered as pure delphinia. (*Journ. de Pharm.*, xix. 519.)

Medical Properties and Uses. The seeds were formerly used as an emetic and cathartic, but have been abandoned in consequence of the violence of their action. Powdered and mixed with lard, they are employed in some cutaneous diseases, and to destroy lice in the hair. An infusion in vinegar has been applied to the same purpose. A preparation made by mixing three parts of the seeds in fine powder with five parts of lard, and maintaining the mixture at the temperature of 212° for twenty-four hours, is recommended by Dr. Bourguignon as very efficacious in the itch. (*Journ. de Pharm.*, 3e *sér.*, xviii. 421.) M. Bazin has obtained good effects from the external and internal use of stavesacre in eczema. He gave the extract in the dose of a grain and a half from four to twelve times a day. (*Ann. de Thérap.*, A. D. 1851, p. 18.) Dr. Turnbull states that he has employed a strong tincture with advantage as an embrocation in rheumatic affections. In some countries the seeds are used to intoxicate fish in the same manner as Cocculus Indicus.

Delphinia is highly poisonous, exerting its effects chiefly on the nervous system. Experiments made by Drs. Falck and Rörig on the lower animals show that, introduced into the rectum, the cellular tissue, or the veins, it produces death by asphyxia, preceded by symptoms of local irritation, convulsive movements, and extreme anæsthesia, without apparent disturbance of the cerebral functions until the moment before death. Introduced into the stomach, it caused salivation, vomiting, and diarrhœa without other signs of absorption. (*Arch. Gén.*, 4e *sér.*, xxx. 482.) Dr. Turnbull, in his work "*On the Medical Properties of the Ranunculaceæ*," states that pure delphinia may be given to the extent of three or four grains a day, in doses of half a grain each, without exciting vomiting, and without producing much intestinal irritation, though it sometimes purges. In most instances it proves diuretic, and gives rise to sensations of heat and tingling in various parts of the body. Externally employed, it acts like veratria, and is applicable to the same complaints; but, according to Dr. Turnbull, produces more redness and burning, and less tingling than that substance. He has employed it in neuralgia, rheumatism, and paralysis. It may be applied by friction, in the form of ointment or alcoholic solution, in proportions varying from ten to thirty grains of the alkaloid to an ounce of the vehicle; and the friction should be continued till a pungent sensation is produced. W.

STATICE. *U. S.*

Marsh Rosemary.

The root of Statice Caroliniana. *U. S.*

Statice. *Sex. Syst.* Pentandria Pentagynia.—*Nat. Ord.* Plumbaginaceæ. *Gen. Ch. Calyx* one-leaved, entire, plaited, scariose. *Petals* five. *Seed* one, superior. *Nuttall.*

Statice Caroliniana. Walter, *Flor. Car.* 118; Bigelow, *Am. Med. Bot.* ii. 51.

This is considered by Nuttall, Torrey, and some other botanists, as a mere variety of the *Statice Limonium* of Europe. Pursh, Bigelow, and others follow Walter in considering it as a distinct species. It is an indigenous maritime plant with a perennial root, sending up annually tufts of leaves, which are obovate or cuneiform, entire, obtuse, mucronate, smooth, and supported on long footstalks. They differ from the leaves of *S. Limonium* in being perfectly flat on the margin, while the latter are undulated. The flower-stem is round, smooth, from a few inches to a foot or more in height, sending off near its summit numerous alternate subdividing branches, which terminate in spikes, and form altogether a loose panicle. The flowers are small, bluish-purple, erect, upon one side only of the common peduncle, with a mucronate scaly bracte at the base of each, a five-angled, five-toothed calyx, and spatulate, obtuse petals.

Marsh rosemary grows in the salt marshes along the seacoast, from New England to Florida, and flowers in August and September. The root, which is the officinal portion, is large, spindle-shaped or branched, fleshy, compact, rough, and of a purplish-brown colour. It is bitter and extremely astringent to the taste, but without odour. Mr. Edward Parrish, of Philadelphia, found it to contain tannic acid, gum, extractive, albumen, volatile oil, resin, caoutchouc, colouring matter, lignin, and various salts, among which were common salt and the sulphates of soda and magnesia. The proportion of tannic acid was 12·4 per cent. (*Am. Journ. of Pharm.*, xiv. 116.)

Medical Properties and Uses. Statice is powerfully astringent, and in some parts of the United States, particularly in New England, is much employed. It may be used for all the purposes for which kino and catechu are given; but its chief popular application is to aphthous and ulcerative affections of the mouth and fauces. Dr. Baylies, of Massachusetts, found it highly useful in cynanche maligna, both as an internal and local remedy. It is employed in the form of infusion or decoction. W.

STILLINGIA. *U. S.*

Queen's-root.

The root of Stillingia sylvatica. *U. S.*

Stillingia. *Sex. Syst.* Monœcia Monadelphia.—*Nat. Ord.* Euphorbiaceæ. *Gen. Ch.* Male. *Involucre* hemispherical, many-flowered, or wanting. *Calyx* tubular, eroded. *Stamens* two and three, exserted. Female. *Calyx* one-flowered, inferior. *Style* trifid. *Capsule* three-grained. *Nuttall.*

From the fruit of *Stillingia sebifera*, the Chinese procure a *vegetable tallow* in large quantities, which is said to be almost pure stearin, and is much used in making candles. It exists between the shell of the seeds, and the outer husk; the kernel, contained within the shell, yielding a liquid oil by expression. (*Pharm. Journ. and Trans.*, xii. 73.)

Stillingia sylvatica. Willd. *Sp. Plant.* iv. 588. This is an indigenous perennial plant, commonly called *Queen's delight*, with herbaceous stems, two or three feet high, and alternate, sessile, oblong or lanceolate-oblong, obtuse, serrulate leaves, tapering at the base, and accompanied with stipules. The male and female flowers are distinct upon the same plant. They are yellow, and arranged in the form of a spike, of which the upper part is occupied by the male, the lower by the female flowers. The male florets are scarcely longer than the bracteal scales.

The plant grows in pine barrens from Virginia to Florida, flowering in May and June. When wounded, it emits a milky juice. The root, which is the part used, is large, thick, and woody. A specimen presented to us by Dr. J. B.

Holmes, of Charleston, S. C., is in long cylindrical pieces, from a third of an inch to more than an inch thick, wrinkled from drying, of a dirty yellowish-brown colour externally, and, when cut across, exhibiting an interior soft yellowish ligneous portion, surrounded by a pinkish-coloured bark. The odour is slight, peculiar, and somewhat oleaginous, but in the recent root is said by Dr. Frost to be strong and acrimonious. The taste is bitterish and pungent, leaving an impression of disagreeable acrimony in the mouth and fauces. It imparts its virtues to water and alcohol. Dr. Frost thinks that the active principle is somewhat volatile, and states that the root loses much of its activity when long kept.

Medical Properties and Uses. In large doses, stillingia is emetic and cathartic, in smaller doses alterative, with some influence over the secretions. It has been long popularly used in South Carolina; but was first introduced to the notice of the profession by Dr. Thomas Young Simons, in a paper published in the *American Medical Recorder* for April, 1828 (vol. xiii. p. 312), as a valuable alterative remedy in syphilitic affections, and others ordinarily requiring the use of mercury. Dr. Simons's statements have been confirmed and extended by Dr. A. Lopez, of Mobile, (*N. Orleans Med. and Surg. Journ.*, iii. 40), and Dr. H. R. Frost, of Charleston, S. C. (*South. Journ. of Med. and Pharm.* for November, 1846). From the reports in its favour there seems no reason to doubt the efficacy of this medicine in secondary syphilis, scrofula, cutaneous diseases, chronic hepatic affections, and other complaints ordinarily benefitted by alterative medicines. It may be given in substance, decoction, or tincture; but the two latter forms are preferable. The dose of the powder is stated at from fifteen to thirty grains. The decoction, made by slowly boiling an ounce of the bruised root in a pint and a quarter of water to a pint, may be given in the quantity of one or two fluidounces three or four times a day, increased as the stomach will bear it. The dose of a tincture made with two ounces of the root and a pint of diluted alcohol is about a fluidrachm. Stillingia is sometimes advantageously combined with sarsaparilla and other alteratives. W.

DATURA. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Solanaceæ.

Gen. Ch. Corolla funnel-shaped, plaited. *Calyx* tubular, angular, deciduous. *Capsule* four-valved. *Willd.*

Datura Stramonium. Willd. *Sp. Plant.* i. 1008; Bigelow, *Am. Med. Bot.* i. 17; Woodv. *Med. Bot.* p. 197, t. 74. The thornapple is an annual plant, of rank and vigorous growth, usually about three feet high, but in a rich soil sometimes rising six feet or more. The root is large, whitish, and furnished with numerous fibres. The stem is erect, round, smooth, somewhat shining, simple below, dichotomous above, with numerous spreading branches. The leaves, which stand on short round footstalks in the forks of the stem, are five or six inches long, of an ovate-triangular form, irregularly sinuated and toothed at the edges, unequal at the base, of a dark-green colour on the upper surface, and pale beneath. The flowers are large, axillary, solitary, and peduncled; having a tubular, pentangular, five-toothed calyx, and a funnel-shaped corolla with a long tube, and a waved plaited border, terminating in five acuminate teeth. The upper portion of the calyx falls with the deciduous parts of the flower, leaving its base, which becomes reflexed and remains attached to the fruit. This is a large, fleshy, roundish-ovate, four-valved, four-celled capsule, thickly covered with sharp spines, and containing numerous seeds, attached to a longitudinal receptacle in the centre of each cell. It opens at the summit.

There are two varieties of this species of Datura, one with green stems and white flowers; the other with a dark-reddish stem minutely dotted with green, and purplish flowers striped with deep purple on the inside. The latter, however, is considered by some botanists as a distinct species, being the *D. Tatula* of Linnæus. The properties of both are the same.

It is doubtful to what country this plant originally belonged. Many European botanists refer it to North America, while we in return trace it to the old continent. Nuttall considers it as having originated in South America or Asia; and it is probable that its native country is to be found in some portion of the East. Its seeds, being retentive of life, are taken in the earth put on shipboard for ballast from one country to another, not unfrequently springing up upon the passage, and thus propagating the plant in all regions which have any commercial connexion. In the United States it is found everywhere in the vicinity of cultivation, frequenting dung-heaps, the road-sides and commons, and other places where a rank soil is created by the deposited refuse of towns and villages. Its flowers appear from May to July or August, according to the latitude. Where the plant grows abundantly, its vicinity may be detected by the rank odour which it diffuses to some distance around. All parts of it are medicinal. The herbaceous portion is directed by the Edinburgh College; the seeds by that of Dublin; the leaves and seeds by the London College; and the leaves, root, and seeds by the U. S. Pharmacopœia. The leaves may be gathered at any time from the appearance of the flowers till the autumnal frost. In this country the plant is generally known by the name of *Jamestown weed*, derived probably from its having been first observed in the neighbourhood of that old settlement in Virginia. In great Britain it is called *thornapple.*

1. The *fresh leaves* when bruised emit a fetid narcotic odour, which they lose upon drying. Their taste is bitter and nauseous. These properties, together with their medical virtues, are imparted to water and alcohol. Water distilled from them, though possessed of their odour in a slight degree, is destitute of their active properties. They contain, according to Promnitz, 0·58 per cent. of gum, 0·6 of extractive, 0·64 of green starch, 0·15 of albumen, 0·12 of resin, 0·23 of saline matters, 5·15 of lignin, and 91·25 of water. The leaves, if carefully dried, retain their bitter taste.

2. The *seeds* are small, kidney-shaped, flattened on the sides, of a dark-brown almost black colour, inodorous, and of the bitter nauseous taste of the leaves, with some degree of acrimony. They were analyzed by Brandes, who found, besides a peculiar alkaline principle called *daturia*, a glutinous matter, albumen,

gum, a butyraceous substance, green wax, resin insoluble in ether, fixed oil, bassorin, sugar, gummy extractive, orange-coloured extractive, and various saline and earthy substances. Chemists, however, have failed to obtain the daturia of Brandes by his own process; and Berzelius states that it has been admitted, even by that chemist himself, to be nothing more than phosphate of magnesia. (*Traité de Chimie*, vi. 319.) But Geiger and Hesse succeeded in isolating an alkaline principle, to which the same name has been given, and which Trommsdorff has repeatedly procured by their process.

As described by Geiger and Hesse, *daturia* crystallizes in colourless, inodorous, shining prisms, which, when first applied to the tongue, are bitterish, but ultimately have a flavour like that of tobacco. It is dissolved by 280 parts of cold, and 72 of boiling water, is very soluble in alcohol, and less so in ether. It has been shown to have a poisonous action upon animals, and strongly dilates the pupil. Crystals of it are asserted to have been obtained from the urine of a person fatally poisoned by stramonium. (See *Am. Journ. of Med. Sci.*, xvi. 485.) It may be procured from the seeds in the same manner as *hyoscyamia* from those of Hyoscyamus niger. (See *Hyoscyamus.*) The product is exceedingly small. In the most favourable case, Trommsdorff got only $\frac{1}{50}$ of one per cent. (*Annal. der Pharm.*, xxxii. 275.) Mr. Morries obtained a poisonous empyreumatic oil by the destructive distillation of stramonium. According to Dr. A. Von Planta, daturia is identical with atropia, its formula being $NC_{34}H_{23}O_6$. (See *Am. Journ. of Pharm.*, xxiii. 38.)

Medical Properties and Uses. Stramonium is a powerful narcotic. When taken in quantities sufficient to affect the system moderately, it usually produces more or less cerebral disturbance, indicated by vertigo, headache, dimness or perversion of vision, and confusion of thought, sometimes amounting to slight delirium or a species of intoxication. At the same time peculiar deranged sensations are experienced about the fauces, œsophagus, and trachea, increased occasionally to a feeling of suffocation, and often attended with nausea. A disposition to sleep is sometimes but not uniformly produced. The pulse is not materially affected. The bowels are rather relaxed than confined, and the secretions from the skin and kidneys not unfrequently augmented. These effects pass off in five or six hours, or in a shorter period, and no inconvenience is subsequently experienced. In poisonous doses, this narcotic produces cardialgia, excessive thirst, nausea and vomiting, a sense of strangulation, anxiety and faintness, partial or complete blindness with dilatation of the pupil, sometimes deafness, flushing and swelling of the face, headache, vertigo, delirium sometimes of a furious, sometimes of a whimsical character, tremors of the limbs, palsy, and ultimately stupor and convulsions. From all these symptoms the patient may recover; but they have frequently terminated in death. To evacuate the stomach by emetics or the stomach pump is the most effectual remedy.

Though long known as a poisonous and intoxicating herb, stramonium was first introduced into regular practice by Baron Störck, of Vienna, who found some advantage from its use in mania and epilepsy. Subsequent observation has confirmed his estimate of the remedy; and numerous cases are on record in which benefit has accrued from it in these complaints. Other diseases in which it has been found beneficial are neuralgic and rheumatic affections, dysmenorrhœa, syphilitic pains, cancerous sores, and spasmodic asthma. In the last complaint it has acquired considerable reputation. It is employed only during the paroxysm, which it very often greatly alleviates or altogether subverts. The practice was introduced into Great Britain from the East Indies, where the natives are in the habit of smoking the dried root and lower part of the stem of *Datura ferox*, in the paroxysms of this distressing complaint. The same parts of *D. Stramonium* were substituted, and found equally effectual. To prepare the roots for use, they

are quickly dried, cut into pieces, and beat so as to loosen the texture. The dried leaves answer the same purpose. They are smoked by means of a common tobacco-pipe. These and other narcotic leaves have also been used in the shape of cigars. The smoke produces a sense of heat in the lungs, followed by copious expectoration, and attended frequently with temporary vertigo or drowsiness, and sometimes with nausea. The remedy should never be used in plethoric cases, unless preceded by ample depletion, and in no case where there is determination to the head. Dangerous and even fatal consequences have resulted from its incautious or improper use; and General Gent, who was instrumental in introducing the practice into England, is said at last to have fallen a victim to it. Stramonium has sometimes been given by the stomach in the same complaint. It is used by Dr. H. D. W. Pawling in the treatment of delirium tremens, and, as represented in the inaugural dissertation of his pupil Dr. G. W. Holstein, with great success. Dr. Pawling employs a decoction of the leaves.

Externally the medicine is used advantageously as an ointment or cataplasm in irritable ulcers, inflamed tumours, swelling of the mammæ, and painful hemorrhoidal affections. Dr. J. Y. Dortch, of North Carolina, has found it very useful in tinea capitis. (*Thesis*, Feb. 1846.) By American surgeons it is very frequently applied to the eye, in order to produce dilatation of the pupil, previously to the operation for cataract; and is found equally efficacious with belladonna. For this purpose the extract, mixed with lard, is generally rubbed over the eyelid, or a solution of it dropped into the eye.

Of the parts of the plant employed, the seeds are the most powerful. They may be given in the dose of a grain twice a day; and an extract made by evaporating the decoction, in one quarter or half the quantity. The dose of the powdered leaves is two or three grains. The inspissated juice of the fresh leaves, which is the officinal extract, is more commonly prescribed than any other preparation, and may be administered in the quantity of one grain. (See *Extractum Stramonii*.) There is also an officinal tincture, to which the reader is referred. The dose should be gradually increased till the narcotic operation becomes evident, or relief from the symptoms of the disease is obtained. Fifteen or twenty grains of the powdered leaves, and a proportionate amount of the other preparations, have often been given daily without unpleasant effects.

Storax, *Fr., Germ.;* Storace, *Ital.;* Estoraque, *Span.*

STYRAX. See BENZOINUM.

Styrax officinale. Willd. *Sp. Plant.* ii. 623; Woodv. *Med. Bot.* p. 291, t. 101. This species of Styrax is a tree which rises from fifteen to twenty-five feet in height, sends off many branches, and is covered with a rough gray bark. The leaves are alternate, petiolate, entire, oval, pointed, bright-green on their upper surface, white with a cotton-like down upon the under, about two inches in length, and an inch and a half in breadth. The flowers are united in clusters of three or four at the extremities of the branches. They are white, and bear considerable resemblance to those of the orange.

This tree is a native of Syria and other parts of the Levant, and has been naturalized in Italy, Spain, and the South of France, where, however, it does

not yield balsam. This circumstance has induced some naturalists to doubt whether *Styrax officinale* is the real source of storax; and, as the *Liquidambar styraciflua* of this country affords a balsam closely analogous to that under consideration, Bernard de Jussieu conjectured that the latter might be derived from another species of the same genus, the *L. orientale* of Lamarck, which is more abundant in Syria than the *Styrax*.

Storax is obtained in Asiatic Turkey by making incisions into the trunk of the tree. Several kinds are mentioned in the books. The purest is the *storax in grains*, which is in whitish, yellowish-white, or reddish-yellow tears, about the size of a pea, opaque, soft, adhesive, and capable of uniting so as to form a mass. Another variety, formerly called *styrax calamita*, from the circumstance, as is supposed, that it was brought wrapped in the leaves of a kind of reed, consists of dry and brittle masses, formed of yellowish agglutinated tears, in the interstices of which is a brown or reddish matter. The French writers call it *storax amygdaloïde*. Both this and the preceding variety have a very pleasant odour like that of vanilla. Neither of them, however, is brought to our markets.

A third variety, which is sometimes sold as the *styrax calamita*, is in brown or reddish-brown masses of various shapes, light, friable, yet possessing a certain degree of tenacity, and softening under the teeth. Upon exposure, it becomes covered upon the surface with a white efflorescence of benzoic acid. It evidently consists of sawdust, united either with a portion of the balsam, or with other analogous substances. As found in our shops, it is usually in the state of a coarse, soft, dark-coloured powder, mingled with occasional light friable lumps of various magnitude, and containing very little of the balsam. When good, it should yield, upon pressure between hot plates, a brown resinous fluid, having the odour of storax.

Another variety, found in our market, is a semi-fluid adhesive matter, called *liquid storax*, which is brown or almost black upon the surface exposed to the air, but of a slightly greenish-gray colour within, and of an odour somewhat like that of the Peruvian balsam, though less agreeable. It is kept in jars, and is the most employed. What is the source of liquid storax is not certainly known. Some suppose it to be derived by decoction from the young branches of *Liquidambar styraciflua;* but some of the genuine juice of this plant, brought from New Orleans, which we have had an opportunity of inspecting, has an odour entirely distinct from that of the substance under consideration. According to Landerer, who resides in Greece, liquid storax is obtained, in the islands of Cos and Rhodes, from the bark and young twigs of Styrax officinale, by subjecting them to pressure. The plant, according to the same authority, grows also on the mainland of Greece, but in that situation does not yield balsam.

General Properties. Storax has a fragrant odour and aromatic taste. It melts with a moderate heat, and when the temperature is raised takes fire and burns with a white flame, leaving a light spongy carbonaceous residue. It imparts its odour to water, which it renders yellow and milky. Its active constituents are dissolved by alcohol and ether. Newmann obtained from 480 grains of storax 120 of watery extract; and from an equal quantity, 360 grains of alcoholic extract. Containing volatile oil and resin, and yielding benzoic or cinnamic acid by distillation, it is entitled to be ranked as a balsam. Besides oil, resin, and benzoic acid, Reinsch found in styrax calamita, gum, extractive, lignin, a matter extracted by potassa, water, and traces of ammonia. Simon found, in liquid storax, cinnamic acid, and a resinous substance which he considered identical with the *styracine* of Bonastre. According to Toel, styracine is a compound of cinnamic acid with a peculiar substance which he calls *styrone*, and is in composition perfectly analogous to the natural fats. (*Chem. Gaz.*, July 2, 1849.)

Medical Properties and Uses. This balsam is a stimulating expectorant, and was formerly recommended in phthisis, chronic catarrh, asthma, and amenor-

rhœa; but it is very seldom used at present, except as a constituent of the compound tincture of benzoin. Liquid storax has been recommended in gonorrhœa and leucorrhœa as equally effectual with copaiba, and less disagreeable. From ten to twenty grains may be given twice a day, and the dose gradually increased.

SUCCINUM. *U. S., Dub.*

Amber.

Succin, Ambre jaune, Karabé, *Fr.;* Bernstein, *Germ.;* Ambra gialla, Succino, *Ital.;* Succino, *Span.*

Amber is a kind of fossil resin, derived, probably, from extinct coniferæ, occurring generally in small detached masses, in alluvial deposits, in different parts of the world. It is found chiefly in Prussia, either on the sea-shore, where it is thrown up by the Baltic, or underneath the surface, in the alluvial formations along the coast. It occurs also in considerable quantities near Catania, in Sicily. It is most frequently associated with lignite, and sometimes encloses insects and parts of vegetables. In the United States, it was found in Maryland, at Cape Sable, near Magothy river, by Dr. Troost. In this locality it is associated with iron pyrites and lignite. It has also been discovered in New Jersey. The amber consumed in this country, however, is brought from the ports of the Baltic.

Properties. Amber is a brittle solid, generally in small irregular masses, permanent in the air, having a homogeneous texture and vitreous fracture, and susceptible of a fine polish. It becomes negatively electric by friction. Its colour is generally yellow, either light or deep; but is occasionally reddish-brown or even deep-brown. It has no taste, and is inodorous unless heated, when it exhales a peculiar, aromatic, not unpleasant smell. It is usually translucent, though occasionally transparent or opaque. Its sp. gr. is about 1·07. Water and alcohol scarcely act on it. When heated in the open air, it softens, melts at 548°, swells, and at last inflames, leaving, after combustion, a small portion of ashes. Subjected to distillation in a retort furnished with a tubulated receiver, it yields, first, a yellow acid liquor; and afterwards a thin yellowish oil, with a yellow waxy substance, which is deposited in the neck of the retort and the upper part of the receiver. This waxy substance, exhausted by cold ether of the part soluble in that menstruum, is reduced to a yellow micaceous substance, identical with the *chrysene* of Laurent. A white crystalline substance, identical with the *idrialine* of Dumas, may be separated from the micaceous substance by boiling alcohol. Both chrysene and idrialine are carbohydrogens. (Pelletier and Walter, *Journ. de Pharm.*, v. 60.) As the distillation proceeds, a considerable quantity of combustible gas is given off, which must be allowed to escape from the tubulure of the receiver. By continuing the heat, the oil gradually deepens in colour, until, towards the end of the distillation, it becomes black and of the consistence of pitch. The oil obtained is called *oil of amber*, and the acid liquor is a solution of impure *succinic acid*. When amber is distilled repeatedly from nitric acid, it yields an acid liquor, from which, after it has been neutralized with caustic potassa, ether separates pure camphor. (Doepping, *Journ. de Pharm.*, vi. 168.) Camphor is also obtained by distilling to dryness powdered amber with an extremely concentrated solution of caustic potassa. (G. Reich, *Ibid.*, xiii. 33, Jan. 1848.)

Composition. According to Berzelius, amber consists of 1. a volatile oil of an agreeable odour in small quantity; 2. a yellow resin, intimately united with a volatile oil, very soluble in alcohol, ether, and the alkalies, easily fusible, and resembling ordinary resins; 3. another resin, also combined with volatile oil, soluble in ether and the alkalies, sparingly soluble in cold, but more soluble in

boiling alcohol; 4. succinic acid; 5. a bituminous principle insoluble in alcohol, ether, and the alkalies, having some analogy to the lac resin of John, and constituting more than four-fifths of the amber. It also contains a strongly odorous, bright-yellow substance, which hardens by time, but preserves in part its odour. The ultimate constituents of amber are carbon 80·59, hydrogen 7·31, oxygen 6·73, ashes (silica, lime, and alumina) 3·27=97·90. (*Drassier*, cited in *Pereira's Elem. of Mat. Med.*)

Pharmaceutical Uses, &c. Amber was held in high estimation by the ancients as a medicine; but at present is employed only in pharmacy and the arts. In pharmacy it is used to prepare oil of amber and succinic acid. (See *Oleum Succini* and *Succinic Acid* in the Appendix.) In the arts it is made into ornaments, and employed in preparing varnishes. When put to the latter use it requires to be first subjected to roasting, whereby it is rendered soluble in a mixture of linseed oil and oil of turpentine. This solution forms *amber varnish*.

Brimstone; Soufre, *Fr.;* Schwefel, *Germ.;* Zolfo, *Ital.;* Azufre, *Span.*

The officinal forms of sulphur are the *sublimed*, the *washed*, and the *precipitated*. The sublimed sulphur is designated in the United States and London Pharmacopœias by the single word *Sulphur;* the washed sulphur in the United States Pharmacopœia by the name *Sulphur Lotum*. The Dublin College has dismissed washed sulphur as an officinal preparation; and the Edinburgh College only recognises sulphur which is free from acidity; calling it "Sulphur Sublimatum" under the Preparations, and "Sulphur" in the Materia Medica list. Sublimed sulphur and washed sulphur will be noticed in this place; the precipitated sulphur in Part II, under the Preparations.

Natural States. Sulphur is very generally disseminated throughout the mineral kingdom, and is almost always present, in minute quantity, in animal and vegetable matter. Among vegetables, it is particularly abundant in the cruciform plants, as for example in mustard. It occurs in the earth, either native or in combination. When native it is found in masses, translucent or opaque, or in the powdery form mixed with various earthy impurities. In combination it is usually united with certain metals, as iron, lead, mercury, antimony, copper and zinc, forming compounds called sulphurets. *Native sulphur* is most abundant in volcanic countries, and is hence called *volcanic sulphur*. The most celebrated mines of native sulphur are found at Solfatara in the kingdom of Naples, in Sicily, and in the Roman States. It occurs, also, in different localities in the United States.

Extraction, &c. Sulphur is obtained either from sulphur earths, or from the native sulphurets of iron and copper, called iron and copper pyrites. The sulphur earths are placed in earthen pots, set in oblong furnaces of brickwork.

From the upper and lateral part of each pot proceeds a tube, which communicates with the upper part of another pot, situated outside the furnace, and perforated near its bottom to allow the melted sulphur to flow out into a vessel containing water, placed beneath. Fire being applied, the sulphur rises in vapour, leaving the impurities behind, and, being condensed again, flows from the perforated pot into the vessel containing the water. Sulphur, as thus obtained, is called *crude sulphur*, and contains about one-twelfth of its weight of earthy matter. For purification, it is generally melted in a cast iron vessel. When the fusion is complete, the impurities subside, and the purer sulphur is dipped out and poured into cylindrical wooden moulds, which give it the form of solid cylinders, about an inch in diameter, called in commerce *roll sulphur* or *cane brimstone*. The dregs of this process, ground to powder, constitute a very impure kind of sulphur, of a gray colour, known in the shops by the name of *sulphur vivum* or *horse brimstone*.

The above process purifies the sulphur but imperfectly. At the same time it causes a considerable loss; as the dregs just mentioned contain a large proportion of sulphur. A more eligible mode of purification consists in distilling the crude sulphur from a large cast iron still, set in brick-work over a furnace, and furnished with an iron head. The head has two lateral communications, one with a chamber of brick-work, the other with an iron receiver, immersed in water, which is constantly renewed to cool it sufficiently to cause the sulphur to condense in the liquid form. When the tube between the still and receiver is shut, and that communicating with the chamber is open, the sulphur condenses on its walls in the form of an impalpable powder, and constitutes *sublimed sulphur* or *flowers of sulphur*. If, on the other hand, the communication with the chamber be closed and that with the receiver opened, the sulphur condenses in the latter in the fused state, and, when cast in cylindrical moulds, forms the *roll sulphur* of commerce.

The extraction of sulphur from the bisulphuret of iron (iron pyrites) is performed by distilling it in stone-ware cylinders. Half the sulphur contained in the bisulphuret is volatilized by the heat, and conducted, by means of an adopter, into vessels containing water, where it condenses. The residue of the mineral is employed for making sulphate of iron, or green vitriol, by exposure to air and moisture. In the island of Anglesea, large quantities of sulphur are obtained from copper pyrites in the process for extracting that metal. The furnaces in which the ore is roasted are connected by horizontal flues with chambers, in which the volatilized sulphur is condensed. Each chamber is furnished with a door, through which the sulphur is withdrawn once in six weeks.

According to Berzelius, a very economical method of extracting sulphur from iron pyrites is practised in Sweden, which saves the expenditure of fuel. The pyrites is introduced into furnaces with long horizontal chimneys, of which the part next to the furnace is of brick-work, while the rest is formed of wood. The pyrites is kindled below, and continues to burn of itself; and the heat generated causes the stratum immediately above the part kindled to give off half its sulphur, which becomes condensed in flowers in the wooden chimney. As the fire advances, the iron and the other half of the sulphur enter into combustion, and, by the increase of heat thus generated, cause the volatilization of a fresh portion of sulphur. In this manner the process continues until the whole of the pyrites is consumed. The sulphur thus obtained is pulverulent and very impure, and requires to be purified by distillation from iron vessels.

Crude sulphur is employed by the manufacturers of sulphuric acid; and, as it is very variable in quality, it becomes important to ascertain its exact value. This may be done by drying a given weight of it, and submitting it to combustion. The weight of the incombustible residue, added to that lost by desiccation, gives the amount of impurity.

Crude sulphur comes to this country principally from Trieste, Messina in Sicily, and the ports of Italy, being imported for the use of the sulphuric acid manufacturers. Roll sulphur and the flowers are usually brought from Marseilles. Good Sicilian sulphur does not contain more than three per cent. of impurity, consisting chiefly of earths.

Properties. Sulphur is an elementary non-metallic brittle solid, of a pale yellow colour, permanent in the air, and exhibiting a crystalline texture and shining fracture. It has a slight taste, and a perceptible smell when rubbed. When pure, its sp. gr. is about 2; but it varies a little in density, according to its molecular state. (*Charles Brame.*) Occasionally, from impurity, its sp. gr. is as high as 2·35. Its equivalent number is 16, and symbol S. It is a bad conductor of heat, and becomes negatively electric by friction. It is insoluble in water, but soluble in alkaline solutions, petroleum, the fixed and volatile oils, and, provided it be in a finely divided state, in alcohol and ether. Upon being heated, it begins to volatilize at about 180°, when its peculiar odour is perceived; it melts at 225°, and, at 600°, in close vessels, boils and rises in the form of a yellow vapour, which may be condensed again, either in the liquid or pulverulent form, according as the temperature of the recipient is above or below the melting point of the sulphur. When heated to 340°, it becomes brownish and viscid, and, by continuing the heat, is rendered more and more so until the temperature reaches to between 450° and 500°. If, in this state, it be suddenly cooled by throwing it into water, it is converted into an allotropic modification of sulphur, called *brown viscid sulphur*, which is used for taking impressions of coins, seals, &c. The same allotropic modification is obtained by precipitation, by acting on sulphuret of copper by aqua regia, which dissolves the copper, and sets the brown sulphur free. In open vessels, sulphur takes fire at about the temperature of 300°, and burns with a blue flame, combining with the oxygen of the air, and giving rise to a peculiar gaseous acid, called sulphurous acid. The combinations of sulphur are numerous, and among the most powerful agents of chemistry. It forms with oxygen four principal acids, the *hyposulphurous*, *sulphurous*, *hyposulphuric*, and *sulphuric*, with hydrogen, *sulphohydric acid* (*hydrosulphuric acid* or *sulphuretted hydrogen*), and with the metals, various *sulphurets*. Some of the sulphurets are analogous to acids, others to bases; and these different sulphurets, by combining with each other, form compounds analogous to salts, and called by Berzelius *sulpho-salts*.

Sulphur, when obtained by roasting the native sulphurets, sometimes contains arsenic, and is thereby rendered poisonous. Sicilian sulphur, being volcanic, is not subject to this impurity. The common English roll sulphur is sometimes made from iron pyrites, and is then apt to contain orpiment (*tersulphuret of arsenic*). This impurity may be detected by heating the suspected sulphur with nitric acid. The arsenic, if present, will be converted into arsenic acid; and the nitric solution, diluted with water, neutralized with carbonate of soda, and acidulated with muriatic acid, will give a yellow precipitate of quintosulphuret of arsenic with a stream of sulphuretted hydrogen. Sulphur, when perfectly pure, is wholly volatilized by heat, and soluble without residue in oil of turpentine. According to Dr. Playfair, nitroprusside of sodium is a delicate test for the soluble sulphurets, producing with them a delicate violet tint. Prof. J. W. Bailey, of West Point, N. Y., has employed the same test for detecting sulphur in any compound. The substance suspected to contain it is heated with carbonate of soda, with the addition of carbonaceous matter if necessary. A small portion of the fused mass, containing the sulphur as sulphuret of sodium, if added to a drop of the nitroprusside, will occasion the characteristic violet tint. (*Silliman's Journ.*, May 1851, p. 351.)

Sublimed sulphur, usually called *flowers of sulphur* (*flores sulphuris*), is in the form of a crystalline powder of a fine yellow colour. It is always contami-

nated with a little sulphuric acid, which is formed at the expense of the oxygen of the air contained in the subliming chambers. It is on this account that sublimed sulphur always reddens litmus; and, if the acid be present in considerable quantity, it sometimes cakes. It may be freed from acidity by careful ablution with hot water, when it becomes the officinal washed sulphur.

Washed sulphur is placed in the list of the Materia Medica in the U. S. Pharmacopœia, with an explanatory note, that it is sublimed sulphur, thoroughly washed with water. The Edinburgh College includes it among the Preparations, and directs it to be prepared by subliming "sulphur," and washing the powder obtained with boiling water until it is freed from acid taste. Washed sulphur has the general appearance of sublimed sulphur, and is wholly volatilized by heat. When properly prepared it does not affect litmus, and undergoes no change by exposure to the atmosphere.

Medical Properties and Uses. Sulphur is laxative, diaphoretic, and resolvent. It is supposed to be rendered soluble by the soda of the bile. It evidently passes off by the pores of the skin; as is shown by the fact that silver, worn in the pockets of patients under a course of it, becomes blackened with a coating of sulphuret. The stools which it occasions are usually solid, and it is gentle in its operation, unless it contain a good deal of acid, when it causes griping; and the liability of the sublimed sulphur to contain acid, renders it less eligible for exhibition than the washed sulphur, from which all acidity is removed. The diseases in which sulphur is principally used are hemorrhoidal affections, chronic rheumatism and catarrh, atonic gout, asthma, and other affections of the respiratory organs unattended with acute inflammation. It is also much employed, both internally and externally, in cutaneous affections, especially scabies, for the cure of which it is considered a specific. In these affections, as well as in chronic rheumatism, it is sometimes applied as an air bath, in the form of sulphurous acid gas, the head being protected from its effects. The dose of sulphur is from one to three drachms, mixed with syrup or molasses, or taken in milk. It is often combined with bitartrate of potassa or with magnesia.

According to M. Hannon, of Belgium, brown viscid sulphur, recently prepared, possesses valuable therapeutic properties, not as a laxative, but as a stimulant to the circulation, lungs, and skin, far more active than ordinary sulphur. The dose of the brown sulphur, obtained by fusion, is from twenty to fifty grains; of the precipitated, which is more active, from five to twenty grains, both given in the form of pill. (*Ann. de Thérap.*, 1852, p. 186.)

Sulphur is consumed in the arts, principally in the manufacture of gunpowder and sulphuric acid.

TABACUM. *U. S., Lond., Ed., Dub.*

Tobacco.

The leaves of Nicotiana Tabacum. *U. S., Lond., Ed., Dub.*

Tabac, *Fr.;* Tabak, *Germ.;* Tobacco, *Ital.;* Tobaco, *Span.*

NICOTIANA. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Solanaceæ.

Gen. Ch. Corolla funnel-shaped, with the border plaited. *Stamens* inclined. *Capsules* two-valved, two-celled. *Willd.*

Nicotiana Tabacum. Willd. *Sp. Plant.* i. 1014; Bigelow, *Am. Med. Bot.* ii. 171; Woodv. *Med. Bot.* p. 208, t. 77. The tobacco is an annual plant, with

a large fibrous root, and an erect, round, hairy, viscid stem, which branches near the top, and rises from three to six feet in height. The leaves are numerous, alternate, sessile, and somewhat decurrent, very large, ovate-lanceolate, pointed, entire, slightly viscid, and of a pale-green colour. The lowest are often two feet long, and six inches broad. The flowers are disposed in loose terminal panicles, and are furnished with long, linear, pointed bractes at the divisions of the peduncle. The calyx is bell-shaped, hairy, somewhat viscid, and divided at its summit into five pointed segments. The tube of the corolla is twice as long as the calyx, of a greenish hue, swelling at top into an oblong cup, and ultimately expanding into a five-lobed, plaited, rose-coloured border. The whole corolla is very viscid. The filaments incline to one side, and support oblong anthers. The pistil consists of an oval germ, a slender style longer than the stamens, and a cleft stigma. The fruit is an ovate, two-valved, two-celled capsule, containing numerous reniform seeds, and opening at the summit.

There is good reason to believe that this plant is a native of tropical America, where it was found by the Spaniards upon their arrival. It is at present cultivated in most parts of the world, and nowhere more abundantly than within the limits of the United States. Virginia is, perhaps, the region most celebrated for its culture. The young shoots, produced from seeds thickly sown in beds, are transplanted into the fields during the month of May, and set in rows with an interval of three or four feet between the plants. Through the whole period of its growth, the crop requires constant attention. The development of the leaves is promoted by removing the top of each plant, and thus preventing it from running into flower and seed. The harvest is in August. The ripe plants, having been cut off above their roots, are dried under cover, and then stripped of their leaves, which are tied in bundles, and packed in hogsheads.

Two varieties of this species are mentioned by authors, one with narrow, the other with broad leaves; but they do not differ materially in properties. Great diversity in the quality of tobacco is produced by difference of soil and mode of cultivation; and several varieties are recognised in commerce. Other species of Nicotiana are also cultivated, especially *N. rustica* and *N. paniculata*, the former of which is said to have been the first introduced into Europe, and is thought to have been cultivated by the aborigines of this country, as it is naturalized near the borders of some of our small northern lakes. The *N. quadrivalvis* of Pursh affords tobacco to the Indians of the Missouri and Columbia rivers; and *N. fructicosa*, a native of China, was probably cultivated in Asia before the discovery of this continent by Columbus.

Properties. Tobacco, as it occurs in commerce, is of a yellowish-brown colour, a strong narcotic penetrating odour which is less obvious in the fresh leaves, and a bitter, nauseous, and acrid taste. These properties are imparted to water and alcohol. They are destroyed by long boiling; and the extract is, therefore, feeble or inert. An elaborate analysis of tobacco was made by Vauquelin, who discovered in it, among other ingredients, an acrid, volatile, colourless substance, slightly soluble in water, very soluble in alcohol, and supposed to be the active principle. It was separated by a complicated process, of which, however, the most important step was the distillation of tobacco juice with potassa. In the results of this distillation Vauquelin recognised alkaline properties, which he ascribed to ammonia, but which were, in part at least, dependent upon the acrid principle alluded to. To this principle the name of *nicotin* was given; but its alkalinity was not ascertained till a subsequent period. Another substance was obtained by Hermstadt by simply distilling water from tobacco, and allowing the liquid to stand for several days. A white crystalline matter rose to the surface, which, upon being removed, was found to have the odour of tobacco, and to resemble it in effects. It was fusible, volatilizable, similar to the nicotin of

Vauquelin in solubility, and without alkaline or acid properties. It was called *nicotianin* by Hermstadt, and appears to partake of the nature of volatile oils. Two German chemists, Posselt and Reimann, subsequently analyzed tobacco, and ascertained the alkaline nature of its active principle, which, however, neither they nor Vauquelin obtained in a state of purity. According to these chemists, 10,000 parts of the fresh leaves contain 6 parts of an alkaline substance, which they call *nicotin*, 1 of the *nicotianin* of Hermstadt, 287 of slightly bitter extractive, 174 of gum mixed with a little malate of lime, 26·7 of green resin, 26 of albumen, 104·8 of a substance analogous to gluten, 51 of malic acid, 12 of malate of ammonia, 4·8 of sulphate of potassa, 6.3 of chloride of potassium, 9·5 of potassa, which was combined in the leaves with malic and nitric acids, 16·6 of phosphate of lime, 24·2 of lime which had been combined with malic acid, 8·8 of silica, 496·9 of lignin, traces of starch, and 8828 parts of water. (Berzelius, *Traité de Chimie.*) According to M. E. Goupet, tobacco also contains a little citric acid. (*Chem. Gaz.*, Aug. 1846, p. 319.) The nicotin obtained by Vauquelin, and by Posselt and Reimann, was a colourless, volatile liquid, and, as subsequently ascertained by MM. Henry and Boutron, was in fact an aqueous solution of the alkaline principle in connexion with ammonia. It was reserved for these chemists to obtain nicotin, or *nicotia*, as it should now be called, in a state of purity. It exists in tobacco combined with an acid in excess, and in this state is not volatile. The following is the process employed by the last-mentioned chemists. Five hundred parts of smoking tobacco were exposed to distillation, in connexion with about 6000 parts of water and 200 parts of caustic soda; the heat applied being at first very moderate, and afterwards increased to the boiling point. The product of the distillation was received in a vessel containing about 30 or 40 parts of sulphuric acid, diluted with three times its weight of water; and the process was continued till nearly one-half of the liquid had come over. The product, in which care was taken to preserve a slight excess of acid, was evaporated to about 100 parts, and was then allowed to cool. A slight deposit which had formed was separated by filtration, an excess of caustic soda was added, and the liquor again distilled. A colourless, very volatile, acrid liquid now came over, which, being concentrated under the receiver of an air-pump, lost the ammonia which accompanied it, and assumed a syrupy consistence, and more or less of the colour of amber. In this liquid, after a few days, minute crystalline plates formed; but, in consequence of their great affinity for moisture, it was difficult to isolate the crystals. This product was pure nicotia.

Nicotia. (*Nicotina. Nicotin.*) This is a colourless or nearly colourless fluid; of the sp. gr. 1·048; remaining liquid at 22° F.; of little smell when cold; of an exceedingly acrid burning taste, even when largely diluted; entirely volatilizable, and, in the state of vapour, very irritant to the nostrils, with an odour recalling that of tobacco; inflammable; very soluble in water, alcohol, ether, the fixed oils, and oil of turpentine; strongly alkaline in its reaction; and capable of forming crystallizable salts with the acids. These salts are deliquescent, have a burning and acrid taste, and, like the salts of ammonia, lose a portion of their base by heat. Nicotia contains a much larger proportion of nitrogen than most of the other organic alkalies. Its formula is $N_2C_{20}H_{14}$, and combining number consequently 162. In its action on the animal system, it is one of the most virulent poisons known. A drop of it in the state of concentrated solution was sufficient to destroy a dog; and small birds perished at the approach of a tube containing it. Tannin forms with it a compound of but slight solubility, and might be employed as a counter-poison. It exists in tobacco in small proportion. Henry and Boutron found different varieties of tobacco to give products varying from 3·8 to 11·28 parts in 1000. It has been found in the seeds, and in very small proportion in the root. (See *Journ. de Pharm.*, xxii. 689.)

There can be little doubt that tobacco owes its activity to this alkali.* It has been employed as a poison. For a very interesting account of it in all its toxicological relations, the reader is referred to a memoir by Orfila, translated by Dr. Lee, and published in the *N. Y. Journ. of Med.* (N. S., ix. 112, 219, and 369). It has the remarkable property of resisting decomposition in the decaying tissues of the body, and it was detected by Orfila in the bodies of animals destroyed by it two or three months after their death.

Nicotianin is probably the odorous principle of tobacco. Posselt and Reimann prepared it by distilling six pounds of the fresh leaves with twelve pounds of water, till one half of the liquid passed over, then adding six pounds more of water, and again distilling, and repeating this process three times. The nicotianin was obtained to the amount of eleven grains, floating on the surface of the water. It was a fatty substance, having the smell of tobacco-smoke, and an aromatic somewhat bitter taste. It was volatilizable by heat, insoluble in water, soluble in alcohol and ether, and not affected by the dilute acids, but dissolved by solution of potassa. This was not obtained by MM. Henry and Boutron. According to Landerer, it does not exist in the fresh leaves, but is generated in the drying process. It produces sneezing when applied to the nostrils, and a grain of it swallowed by Hermstadt occasioned giddiness and nausea.

When distilled at a temperature above that of boiling water, tobacco affords an empyreumatic oil, which Mr. Brodie proved to be a most virulent poison. A single drop injected into the rectum of a cat occasioned death in about five minutes, and double the quantity, administered in the same manner to a dog, was followed by the same result. This oil is of a dark-brown colour, and an acrid taste, and has a very peculiar smell, exactly resembling that of tobacco pipes which have been much used. It has been shown to contain nicotia. (*Ann. de Chim. et de Phys.*, 3e *sér.*, ix. 465.)

Medical Properties and Uses. Tobacco unites with the powers of a sedative narcotic, those of an emetic and diuretic; and produces these effects to a greater or less extent to whatever surface it may be applied. In addition, when snuffed up the nostrils, it excites violent sneezing and a copious secretion of mucus; when chewed, it irritates the mucous membrane of the mouth, and increases the flow of saliva; and, when injected into the rectum, it sometimes operates as a cathartic. Moderately taken, it quiets restlessness, calms mental and corporeal inquietude, and produces a state of general languor or repose, which has great charms for those habituated to the impression. In larger quantities, it gives rise to confusion of the head, vertigo, stupor, faintness, nausea, vomiting, and general debility of the nervous and circulatory functions, which, if increased, eventuates in alarming and even fatal prostration. The symptoms of its excessive action are severe retching, with the most distressing and continued nausea, great feebleness of pulse, coolness of the skin, fainting, and sometimes convulsions. It probably operates both through the medium of the nervous system,

* M. Schloesing obtained a much larger proportion than that stated above by the following process. Tobacco is exhausted by boiling water, the infusion evaporated to a semi-solid consistence, and the extract shaken with twice its volume of alcohol of 36°. Two layers form, of which the upper contains all the nicotia. This is decanted, most of the alcohol evaporated, and alcohol anew added in order to precipitate certain matters. The extract is treated with a concentrated solution of potassa, and, after cooling, is shaken with ether, which dissolves the nicotia. To the ethereal solution powdered oxalic acid is added, which unites with the nicotia, and separates in the form of a syrupy mass. This being washed with ether, treated with potassa, taken up by water, and distilled in a salt-water bath, yields the nicotia, which may be obtained pure by rectification in a current of hydrogen. (*Journ. de Pharm.*, 3e sér., xii. 157.) Orfila, in his memoir on nicotia, states that Havana tobacco yields 2 per cent. of this alkaloid, Maryland, 2·3 per cent., and Virginia 6·9 per cent.

and by entering the circulation. As its local action is stimulant, we can thus account for the fact, that it excites the functions of the kidneys, at the same time that it reduces the nervous and secondarily the arterial power. The experiments of Brodie lead to the inference that the function of the heart is affected by tobacco, through the medium of the nervous system; for in a decapitated animal in which the circulation was sustained by artificial respiration, the infusion injected into the rectum did not diminish the action of the heart; while, on the contrary, this organ almost immediately ceased to contract, when an equal dose of the poison was administered to a healthy animal. Mr. Brodie observed a remarkable difference between the operation of the infusion and that of the empyreumatic oil. After death from the former the heart was found completely quiescent, while it continued to act with regularity for a considerable time after apparent death from the latter. We may infer from this fact, either that there are two poisonous principles in tobacco, or that a new narcotic product is formed during its destructive distillation. In cases of poisoning from tobacco, the indications are, after the evacuation of the poison, to support the system by external and internal stimulants, and to allay irritation of stomach by the use of opiates.

The use of tobacco was adopted by the Spaniards from the American Indians. In the year 1560, it was introduced into France by the ambassador of that country at the court of Lisbon, whose name—Nicot—has been perpetuated in the generic title of the plant. Sir Walter Raleigh is said to have introduced the practice of smoking into England. In the various modes of smoking, chewing, and snuffing, the drug is now largely consumed in every country on the globe. It must have properties peculiarly adapted to the propensities of our nature, to have thus surmounted the first repugnance to its odour and taste, and to have become the passion of so many millions. When employed in excess, it enfeebles digestion, produces emaciation and general debility, and lays the foundation of serious nervous disorders. The late Dr. Chapman informed us that he had met with several instances of mental disorder, closely resembling delirium tremens, which resulted from its abuse, and which subsided in a few days after it had been abandoned; and Dr. Kirkbride, in the *Annual Report of the Pennsylvania Hospital for the Insane for* 1850, refers to four cases of insanity, the origin of which was ascribed to the abuse of tobacco.

Its remedial employment is less extensive than might be inferred from the variety of its powers. The excessive and distressing nausea which it is apt to occasion, interferes with its internal use; and it is very seldom administered by the stomach. As a narcotic it is employed chiefly to produce relaxation in spasmodic affections. For this purpose, the infusion or smoke of tobacco, or the leaf in substance in the shape of a suppository, is introduced into the rectum in cases of strangulated hernia, obstinate constipation from spasm of the bowels, and retention of urine from a spasmodic stricture of the urethra. For a similar purpose, the powdered tobacco, or common snuff, mixed with simple cerate, as recommended by the late Dr. Godman, is sometimes applied to the throat and breast in cases of croup; and Dr. Chapman directed the smoking of a cigar in the same complaint, with decided benefit. One of the worst cases of spasm of the rima glottidis which we have seen, and which resisted powerful depletion by the lancet, yielded to the application of a tobacco cataplasm to the throat. A similar application to the abdomen is highly recommended in painters' colic, and has proved useful in hysterical convulsions. Tetanus is said to have been cured by baths made with the decoction of the fresh leaves. The relaxation produced by smoking, in a person unaccustomed to it, was very happily resorted to by Dr. Physick, in a case of obstinate and long-continued dislocation of the jaw; and the same remedy has frequently been found useful in the paroxysm of spasmodic asthma. Tobacco has been highly recommended, in the form of

cataplasm, in articular gout and rheumatism; and has been employed in the same way, as well as by injection, in cases of obstinate verminose affections. As an emetic it is seldom employed, unless in the shape of a cataplasm to the epigastrium, to assist the action of internal medicines in cases of great insensibility of stomach. As a diuretic it was used by Fowler in dropsy and dysury; but the practice is not often imitated. There is no better errhine than tobacco, for the ordinary purposes for which this class of medicines is employed. As a sialagogue, it is beneficial in rheumatism of the jaws, and often relieves toothache by its anodyne action. It is also used externally in the shape of cataplasm, infusion, or ointment, in cases of tinea capitis, psora, and some other cutaneous affections. The empyreumatic oil mixed with simple ointment, in the proportion of twenty drops to the ounce, has been applied with advantage, by American practitioners, to indolent tumours and ulcers; but, in consequence of its liability to be absorbed, and to produce unpleasant effects on the system, it should be used with great caution. (See *Oleum Tabaci.*) This remark is applicable to all the modes of employing tobacco; particularly to the injection of the infusion into the rectum, which has in several instances caused the death of the patient. It is even more dangerous than a proportionate quantity introduced into the stomach; as, in the latter case, the poison is more apt to be rejected. Even the external application of the leaves or powder is not without danger, especially when the cuticle is removed. A case of death is on record, occurring in a child eight years old, in consequence of the application of the expressed juice of the leaves to the head, for the cure of tinea capitis. Death has also been produced in several instances by the inhalation of the smoke.

Five or six grains of powdered tobacco will generally act as an emetic; but the remedy is not given in this shape. The infusion used in dropsy by Fowler was made in the proportion of an ounce to a pint of boiling water, and given in the dose of sixty or eighty drops. The officinal infusion, which is employed for injection, is much weaker. (See *Infusum Tabaci.*) A wine and an ointment of tobacco are directed by the U. S. Pharmacopœia.

TAMARINDUS. *U. S., Lond., Ed.*

Tamarinds.

The preserved fruit of Tamarindus Indica. *U. S.* Pulp of the fruit. *Lond.* Pulp of the pods of Tamarindus indica. *Ed.*

Off. Syn. PULP OF TAMARINDS. Tamarindicus Indica. The pulp of the pods. *Dub.*

Tamarins, *Fr.;* Tamarinden, *Germ.;* Tamarindi, *Ital.;* Tamarindos, *Span.*

TAMARINDUS. *Sex. Syst.* Monadelphia Triandria.—*Nat. Ord.* Fabaceæ or Leguminosæ.

Gen. Ch. Calyx four-parted. *Petals* three. *Nectary* with two short bristles under the filaments. *Legume* filled with pulp. *Willd.*

Tamarindus Indica. Willd. *Sp. Plant.* iii. 577; Woodv. *Med. Bot.* p. 448, t. 161. The tamarind tree is the only species of this genus. It rises to a great height, sends off numerous spreading branches, and has a beautiful appearance. The trunk is erect, thick, and covered with a rough, ash-coloured bark. The leaves are alternate and pinnate, composed of many pairs of opposite leaflets, which are almost sessile, entire, oblong, obtuse, unequal at their base, about half an inch long by a sixth of an inch broad, and of a yellowish-green colour. The flowers, which are in small lateral racemes, have a yellowish calyx, and petals which are also yellow, but beautifully variegated with red veins. The

fruit is a broad, compressed, reddish ash-coloured pod, very much curved, from two to six inches long, and with numerous brown, flat, quadrangular seeds, contained in cells formed by a tough membrane. Exterior to this membrane is a light-coloured acid pulpy matter, between which and the shell are several tough ligneous strings, running from the stem to the extremity of the pod, the attachment of which they serve to strengthen. The shells are very fragile and easily separated.

Tamarindus Indica appears to be a native of the East and West Indies, Egypt, and Arabia, though believed by some authors to have been imported into America. De Candolle is doubtful whether the East and West India trees are of the same species. The pods of the former are much larger than those of the latter, and contain a greater number of seeds. At least such is the statement made by authors, who inform us that East India tamarinds contain six or seven seeds, those from the West Indies rarely more than three or four. We found, however, in a parcel of the latter in our possession, numerous pods with from eight to ten seeds, and the number generally exceeded four. The fruit is the officinal portion.

Tamarinds are brought to us chiefly, if not exclusively, from the West Indies, where they are prepared by placing the pods, previously deprived of their shell, in layers in a cask, and pouring boiling syrup over them. A better mode, sometimes practised, is to place them in stone jars, with alternate layers of powdered sugar. They are said to be occasionally prepared in copper boilers.

Properties. Fresh tamarinds, which are sometimes, though rarely, brought to this country, have an agreeable sour taste, without any mixture of sweetness. As we usually find them, in the preserved state, they form a dark-coloured adhesive mass, consisting of syrup mixed with the pulp, membrane, strings, and seeds of the pod, and of a sweet acidulous taste. The seeds should be hard, clean, and not swollen, the strings tough and entire, and the smell without mustiness. From the analysis of Vauquelin, it appears that in 100 parts of the pulp of tamarinds, independently of the sugar added to them, there are 9·40 parts of citric acid, 1·55 of tartaric acid, 0·45 of malic acid, 3·25 of bitartrate of potassa, 4·70 of gum, 6·25 of jelly, 34·35 of parenchymatous matter, and 27·55 of water; so that the acidity is chiefly owing to the presence of citric acid. It is said that copper may sometimes be detected in preserved tamarinds, derived from the boilers in which they are occasionally prepared. Its presence may be ascertained by the reddish coat which it imparts to the blade of a knife immersed in the tamarinds.

Medical Properties and Uses. Tamarinds are laxative and refrigerant, and infused in water form a highly grateful drink in febrile diseases. Convalescents often find the pulp a pleasant addition to their diet, and useful by preserving the bowels in a loose condition. It is sometimes prescribed in connexion with other mild cathartics, and is one of the ingredients of the confection of senna. Though frequently prescribed with the infusion of senna to cover the taste of that medicine, it is said to weaken its purgative power; and the same observation has been made of its influence upon the resinous cathartics in general. From a drachm to an ounce or more may be taken at a dose.

TANACETUM. *U. S. Secondary.*

Tansy.

The herb of Tanacetum vulgare. *U. S.*

Tanaisie, *Fr.;* Gemeiner Rheinfarrn, Wurmkraut, *Germ ;* Tanaceto, *Ital., Span.*

Tanacetum. *Sex. Syst.* Syngenesia Superflua.—*Nat. Ord.* Compositæ-Senecionideæ, *De Candolle;* Asteraceæ, *Lindley.*

Gen. Ch. Receptacle naked. *Pappus* somewhat marginate. *Calyx* imbricate, hemispherical. *Corolla* rays obsolete, trifid. *Willd.*

Tanacetum vulgare. Willd. *Sp. Plant.* iii. 1814; Woodv. *Med. Bot.* p. 66, t. 27. This is a perennial herbaceous plant, rising two or three feet in height. The stems are strong, erect, obscurely hexagonal, striated, often reddish, branched towards the summit, and furnished with alternate, doubly pinnatifid leaves, the divisions of which are notched or deeply serrate. The flowers are yellow, and in dense terminal corymbs. Each flower is composed of numerous florets, of which those constituting the disk are perfect and five-cleft, those of the ray very few, pistillate, and trifid. The calyx consists of small, imbricated, lanceolate leaflets, having a dry scaly margin. The seeds are small, oblong, with five or six ribs, and crowned by a membranous pappus.

Tansy is cultivated in our gardens, and grows wild in the roads and in old fields; but was introduced from Europe, where it is indigenous. It is in flower from July to September.

There is a variety of the plant with curled leaves, which is said to be more grateful to the stomach than that above described, but has less of the peculiar sensible properties of the herb, and is probably less active.

The odour of tansy is strong, peculiar, and fragrant, but much diminished by drying; the taste is warm, bitter, somewhat acrid, and aromatic. These properties are imparted to water and alcohol. According to Peschier, the leaves contain volatile oil, fixed oil, wax or stearin, chlorophylle, yellow resin, yellow colouring matter, tannic and gallic acids, bitter extractive, gum, lignin, and a peculiar acid which he calls *tanacetic*, and which precipitates lime, baryta, oxide of lead, and oxide of copper. The medical virtues of the plant depend on the bitter extractive and volatile oil. The latter, when separated by distillation, has a greenish-yellow colour, with the flavour of the plant, is lighter than water, and deposits camphor upon standing. The seeds contain the largest proportion of the bitter principle, and the least of volatile oil.

Medical Properties and Uses. Tansy has the medical properties common to the aromatic bitters. It has been recommended in intermittents, hysteria, amenorrhœa, and as a preventive of arthritic paroxysms; but at present it is chiefly used as an anthelmintic, and in this country is scarcely employed, for any purpose, in regular practice. The seeds are said to be most effectual as a vermifuge. The dose of the powder is from thirty grains to a drachm two or three times a day; but the infusion is more frequently administered. A fatal case of poisoning with half an ounce of oil of tansy is recorded in the *Medical Magazine* for November, 1834. Frequent and violent clonic spasms were experienced, with much disturbance of respiration; and the action of the heart gradually became weaker till death took place from its entire suspension. No inflammation of the stomach or bowels was discovered upon dissection. (*Am. Journ. of the Med. Sci.*, xvi. 256.) Two other fatal cases have since been recorded, one in which more than a fluidounce was taken, the other only a fluidrachm. In both death followed speedily, preceded by coma and violent convulsions. In two of the three cases above referred to, the oil seems to have been taken with the view of producing abortion, but no such effect followed in either. (*Ibid.*, xxiii. 136, and xxiv. 279.) W.

TAPIOCA. *U. S., Ed., Dub.*

Tapioca.

The fecula of the root of Janipha Manihot. *U. S., Ed., Dub.*

Janipha. *Sex. Syst.* Monœcia Monadelphia.—*Nat. Ord.* Euphorbiaceæ.

Gen. Ch. Calyx campanulate, five-parted. *Stamens* ten, distinct, alternately

shorter. *Stigmas* three, many-lobed. *Fruit* three-celled, with solitary seeds. (Lindley, *Med. and Æconom. Bot.*, 82.)

Botanists have generally followed Kunth in separating this genus from Jatropha. Its name was derived from the Indian designation of another species.

Janipha Manihot. Curtis's *Bot. Mag.* 3071.—*Jatropha Manihot.* Willd. *Sp. Plant.* iv. 562. This is the *cassava* plant of the West Indies, the *mandioca* or *tapioca* of Brazil. It is a shrub about six or eight feet in height, with a very large, white, fleshy, tuberous root, which often weighs thirty pounds. The stem is round, jointed, and furnished at its upper part with alternate petiolate leaves, deeply divided into three, five, or seven oval-lanceolate, very acute lobes, which are somewhat wavy upon their borders, of a deep-green colour on their upper surface, glaucous and whitish beneath. The flowers are in axillary racemes.

Janipha Manihot is a native of South America, and is cultivated extensively in the West Indies, Brazil, and other parts of tropical America, for the sake of its root, which is much employed as an article of food. The plant is of quick growth, and the root arrives at perfection in about eight months. There are two varieties, distinguished by the names of *sweet* and *bitter*. The root of the former may be eaten with impunity; that of the latter, which is most extensively cultivated, abounds in an acrid milky juice, which renders it highly poisonous if eaten in the recent state. By MM. Henry and Boutron-Charlard it has been ascertained that the bitter cassava owes its poisonous properties to the presence of hydrocyanic acid. (*Journ. de Pharm.*, xxii. 119.) Both varieties contain a large proportion of starch. The root is prepared for use by washing, scraping, and grating or grinding it into a pulp, which, in the case of the bitter variety, is submitted to pressure so as to separate the deleterious juice. It is now in the state of meal or powder, which is made into bread, cakes, or puddings. As the poisonous principle is volatile, the portion which may have remained in the meal is entirely dissipated by the heat employed in cooking. The preparation denominated tapioca among us is obtained from the expressed juice. This, upon standing, deposits a powder, which, after repeated washings with cold water, is nearly pure starch. It is dried by exposure to heat, which renders it partly soluble in cold water, and enables it to assume the consistence by which it is characterized. When dried without heat, it is pulverulent, and closely resembles the fecula of arrow-root.

Tapioca is in the form of irregular, hard, white, rough grains, possessing little taste, partially soluble in cold water, and affording a fine blue colour when iodine is added to its filtered solution. The partial solubility in cold water is owing to the rupture of the starch-granules by heat. Examined under the microscope, the granules appear partly broken, partly entire. The latter are muller-shaped, about the two-thousandth of an inch in diameter, more uniform in size than the granules of most other varieties of fecula, with a distinct hilum which is surrounded by rings, and cracks in a stellate manner. The tapioca meal, called sometimes Brazilian arrow-root, and by the French *moussache*, is the fecula dried without heat. Its granules are identical with those already described. Being nutritious, and at the same time easy of digestion, and destitute of all irritating properties, tapioca forms an excellent diet for the sick and convalescent. It is prepared for use by boiling it in water. Lemon juice and sugar will usually be found grateful additions; and, in low states of disease or cases of debility, it may be advantageously impregnated with wine and nutmeg or other aromatic.

A factitious tapioca is found in the shops, consisting of very small, smooth, spherical grains, and supposed to be prepared from potato starch. It is sold under the name of *pearl tapioca*. W.

LEONTODON. *Sex. Syst.* Syngenesia Æqualis.—*Nat. Ord.* Compositæ-Cichoraceæ, *De Candolle;* Cichoraceæ, *Lindley.*

Gen. Ch. Receptacle naked. *Calyx* double. *Seed-down* stipitate, hairy. *Willd.*

Leontodon Taraxacum. Willd. *Sp. Plant.* iii. 1544; Woodv. *Med. Bot.* p. 39, t. 16.—*Taraxacum Dens-leonis.* De Cand. *Prodrom.* vii. 145. The dandelion is an herbaceous plant, with a perennial fusiform root. The leaves, which spring immediately from the root, are long, pinnatifid, generally runcinate, with the divisions toothed, smooth, and of a fine green colour. The common name of the plant was derived from the fancied resemblance of its leaves to the teeth of a lion. The flower-stem rises from the midst of the leaves, six inches or more in height. It is erect, simple, naked, smooth, hollow, fragile, and terminated by a large golden-coloured flower, which closes in the evening, and expands with the returning light of the sun. The calyx is smooth and double, with the outer scales bent downwards. The florets are very numerous, ligulate, and toothed at their extremities. The receptacle is convex and punctured. The seed-down is stipitate, and at the period of maturity is disposed in a spherical form, and is so light and feathery as to be easily borne away by the wind, with the seeds attached.

This species of Leontodon grows spontaneously in most parts of the globe. It is abundant in this country, adorning our grass-plats and pasture-grounds with its bright-yellow flowers, which, in moist places, show themselves with the first opening of spring, and continue to appear till near the close of summer. All parts of the plant contain a milky bitterish juice, which exudes when they are broken or wounded. The leaves, when very young, and blanched by the absence of light during their growth, are tender and not unpleasant to the taste, and on the continent of Europe are sometimes used as a salad. When older and of their natural colour, they are medicinal. The Pharmacopœias recognise only the root, which is by far the most efficacious part. It should be full grown when collected, and should be employed in the recent state, as it is then most active. It does not, however, as stated by Duncan, lose nearly all its bitterness by drying; and the root dug up in the warmer seasons might, if dried with care, be employed with propriety in the succeeding winter. The juice of the root is thin and watery in the spring; milky, bitter, and spontaneously coagulable in the latter part of summer and autumn; and sweet and less bitter in the winter, when affected by the frost. The months of July, August, and September are, therefore, the proper period for collecting it.

The fresh full-grown root of the dandelion is several inches in length, as thick as the little finger or thicker, round and tapering, somewhat branched, of a light-brown colour externally, whitish within, having a yellowish ligneous cord running through its centre, and abounding in a milky juice. In the dried state it is much shrunk, wrinkled longitudinally, brittle, and when broken presents a shining somewhat resinous fracture. It is without smell, but has a sweetish, mucilaginous, bitterish, herbaceous taste. Its active properties are yielded to water by boiling, and do not appear to be injured in the process. The milky

juice, examined by John, was found to contain bitter extractive, gum, caoutchouc, saline matters, a trace of resin, and a free acid. Besides these ingredients, starch or inulin, and saccharine matter exist in the root. Mannite, which has been found in the infusion of the root, has been demonstrated by the Messrs. Smith, of Edinburgh, not to pre-exist in the root, but to be formed by spontaneous changes consequent on exposure. (*Pharm. Journ. and Trans.*, viii. 481.) A crystallizable principle has been extracted from the juice of the root by M. Pollex, who has named it *taraxacin*. It is bitter and somewhat acrid, fusible but not volatile, sparingly soluble in cold water, but very soluble in boiling water, alcohol, and ether. It is obtained by boiling the milky juice in distilled water, filtering the concentrated liquor, and allowing it to evaporate spontaneously in a warm place. The taraxacin crystallizes, and may be purified by repeated solution and crystallization in alcohol or water. (*Pharm. Journ. and Transact.*, i. 425.)

The root of *Aspargia hispida* has been largely substituted for dandelion in England by the herb gatherers (*Pharm. Journ. and Trans.*, xi. 107); and we are informed that a similar fraudulent substitution is not unfrequent, in this country, of the root of *Cichorium Intibus*, or *chicory*. This is distinguishable from the genuine root by its lighter colour, and greater bitterness.

Medical Properties and Uses. Taraxacum is slightly tonic, diuretic, and aperient, and is thought to have a specific action upon the liver, exciting it when languid to secretion, and resolving its chronic engorgements. It has been much employed in Germany, and is a popular remedy with many practitioners in this country. The diseases to which it appears to be especially applicable, are those connected with derangement of the hepatic apparatus, and of the digestive organs generally. In congestion and chronic inflammation of the liver and spleen, in cases of suspended or deficient biliary secretion, and in dropsical affections dependent on obstruction of the abdominal viscera, it appears to be capable of doing good, if employed with a due regard to the degree of excitement. Our own experience is in its favour. An irritable condition of the stomach and bowels, and the existence of acute inflammation, contra-indicate its employment. It is usually given in the form of extract or decoction, though some prefer the infusion. (See these preparations in the second part of this work.) Bitartrate of potassa is sometimes added to the decoction when an aperient effect is desired; and aromatics will occasionally be found useful in correcting a tendency to griping or flatulence. The root is sometimes prepared and ground with coffee, the taste of which covers that of the dandelion. (*Pharm. Journ. and Trans.* xii. 505.)

The term *turpentine* is now generally applied to certain vegetable juices, liquid or concrete, which consist of resin combined with a peculiar essential oil, called *oil of turpentine.* They are generally procured from different species of pine, fir, or larch, though other trees afford products which are known by the same general title, as for instance the *Pistacia Terebinthus*, which yields the Chian turpentine. Some of the French writers extend the name of turpentine to other juices consisting of resin and essential oil, without benzoic or cinnamic acid, as copaiba, balm of Gilead, &c. We shall describe particularly, in this place, only the officinal turpentines. A brief botanical view of the plants from which they are respectively derived, will be in accordance with the plan of this work. It is proper first to observe that the original genus Pinus of Linnæus has been divided into the three genera, Pinus, Abies, and Larix, which are now very generally recognised, though Lindley unites the two latter in his Flora Medica.

Pinus. *Sex. Syst.* Monœcia Monadelphia.—*Nat. Ord.* Pinaceæ or Coniferæ. *Gen. Ch. Flowers* monœcious. Males. *Catkins* racemose, compact, and terminal; squamose; the scales staminiferous at the apex. *Stamens* two; the *anthers* one-celled. Females. *Catkins* or *cones* simple, imbricated with acuminate scales. *Ovaries* two. *Stigmas* glandular. *Scales* of the cone oblong, club-shaped, woody; umbilicato-angular at the apex. *Seeds* in pairs, covered with a sharp-pointed membrane. *Cotyledons* digitato-partite. *Leaves* two or many, in the same sheath. (*Pereira's Mat. Med.* from *Bot. Gall.*)

1. *Pinus palustris.* Willd. *Sp. Plant.* iv. 499.—*P. Australis.* Michaux, *N. Am. Sylv.* iii. 133. "Leaves in threes, very long; stipules pinnatifid, ramentaceous, persistent; strobiles subcylindrical, armed with sharp prickles."

This is a very large indigenous tree, growing in dry, sandy soils, from the southern part of Virginia to the Gulf of Mexico. Its mean elevation is sixty or seventy feet, and the diameter of its trunk about fifteen or eighteen inches for two-thirds of this height. The leaves are about a foot in length, of a brilliant green colour, and united in bunches at the ends of the branches. The names by which the tree is known in the Southern States are *long-leaved pine*, *yellow pine*, and *pitch pine;* but the first is most appropriate, as the last two are applied also to other species. This tree furnishes by far the greater proportion of the turpentine, tar, &c., consumed in the United States, or sent from this to other countries. (See *Pix Liquida.*)

2. *Pinus Tæda.* Willd. *Sp. Plant.* iv. 498; Michaux, *N. Am. Sylv.* iii. 156. "Leaves in threes, elongated, with elongated sheaths; strobiles oblong-conical, deflexed, shorter than the leaf; spines inflexed."

This is the *loblolly*, or *old field pine* of the Southern States. It is abundant in Virginia, where it occupies the lands which have been exhausted by cultivation. It exceeds eighty feet in height, has a trunk two or three feet in diameter,

and expands into a wide spreading top. The leaves are about six inches long, and of a light-green colour. It yields turpentine in abundance, but less fluid than that which flows from the preceding species.

3. *Pinus sylvestris.* Willd. *Sp. Plant.* iv. 494; Woodv. *Med. Bot.* p. 1, t. 1; Michaux, *N. Am. Sylv.* iii. p. 125. "Leaves in pairs, rigid; strobiles ovate-conical, of the length of the leaves; scales echinate."

This species of pine, when of full size, is eighty feet high, with a trunk four or five feet in diameter. It inhabits the northern and mountainous parts of Europe. In Great Britain it is called the *wild pine*, or *Scotch fir;* the latter name having been applied to it from its abundance in the mountains of Scotland. It yields a considerable proportion of the common European turpentine.

Besides the pines above described, various others yield medicinal products. *Pinus maritima* (*P. Pinaster* of Aiton and Lambert), growing in the southern and maritime parts of Europe, yields much of the turpentine, pitch, and tar consumed in France, and is admitted among the officinal plants in the French Codex. From the branches of *Pinus Pumilio*, which inhabits the mountains of Eastern and South-eastern Europe, a terebinthinate juice exudes spontaneously, called *Hungarian balsam. Pinus Cembra*, or the *Siberian stone-pine* of the Alps and Carpathian mountains, is said to afford the product called *Carpathian balsam;* and the seeds both of that species, and of *Pinus Pinea*, or *stone-pine* of the South of Europe and North of Africa, are used in Europe in desserts, under the name of *pine nuts.* The *Pinus rigida*, or *pitch pine* of this country, and probably others besides those mentioned, are sometimes employed in the preparation of tar.

Abies. See PIX BURGUNDICA.

Abies balsamea. Lindley, *Flor. Med.* p. 554. — *A. balsamifera.* Michaux, *N. Am. Sylv.* iii. 191.—*Pinus balsamea*, Willd. *Sp. Plant.* iv. 504. "Leaves solitary, flat, emarginate or entire, glaucous beneath, somewhat pectinate, sub-erect above, recurved, spreading; cones cylindrical, erect; bractes abbreviate, obovate, conspicuously mucronate, sub-serrulate."

This is the *American silver fir*, or *balm of Gilead tree*, inhabiting Canada, Nova Scotia, Maine, and the mountainous regions further to the south. It is an elegant tree, seldom rising more than forty feet in height, with a tapering trunk, and numerous branches, which diminish in length in proportion to their height, and form an almost perfect pyramid. The leaves are six or eight lines long, inserted in rows on the sides and tops of the branches, narrow, flat, rigid, bright-green on their upper surface, and of a silvery whiteness beneath. The cones are large, erect, nearly cylindrical, of a purplish colour, and covered with a resinous exudation which gives them a glossy, rich, and beautiful appearance. It is from this tree that the *Canada balsam* is obtained.

Several other species of Abies are officinal. *Abies excelsa* of Europe, and *A. Canadensis* of the United States, have already been described as the sources respectively of Burgundy and Canada pitch. (See *Pix Burgundica* and *Pix Canadensis.*) The *A. Picea* (*Abies pectinata* of De Candolle, *A. taxifolia* of the French Codex, *Pinus Picea* of Linnæus), or *European silver fir*, growing in the mountainous regions of Switzerland, Germany, and Siberia, yields the *Strasburg turpentine*, which is much used in some parts of Europe. The *Abies nigra* (*Pinus nigra*), or *black spruce* of this country, yields a product, which, though not recognised by the Pharmacopœia, is considerably employed. The substance alluded to is the *essence of spruce*, prepared from the young branches by boiling them in water, and evaporating the decoction. It is a thick liquid, having the colour and consistence of molasses, with a bitterish, acidulous, astringent taste. It is much used in the preparation of the beverage commonly known by the

name of *spruce beer*, which is a pleasant and wholesome drink in summer, and useful in long sea-voyages as a preventive of scurvy.*

Larix. Sex. Syst. Monœcia Monadelphia. — *Nat. Ord.* Pinaceæ or Coniferæ.

Gen. Ch. As in Abies, except that the *cotyledons* are simple, and never lobed; the *cones* lateral; the *leaves*, when first expanding, in tufted fascicles, becoming somewhat solitary by the elongation of the new branch. (*Pereira's Mat. Med.* from *Bot. Gall.*)

Larix Europæa. De Cand. *Flor. Fr.* 2064. — *Abies Larix.* Lamb. *Illust.* t. 785, f. 2. — *Pinus Larix.* Willd. *Sp. Plant.* iv. 503; Woodv. *Med. Bot.* p. 7, t. 4. "Leaves fascicled, deciduous; cones ovate-oblong; margins of the scales reflexed, lacerated; bractes panduriform."

The *European larch* is a large tree, inhabiting the mountains of Siberia, Switzerland, Germany, and the East of France. It yields the *Venice turpentine* of commerce, and a peculiar sweetish substance, called in France *Briançon manna*, which exudes spontaneously, and concretes upon its bark. When the larch forests of Russia take fire, a juice exudes from the trunk during their combustion, which concretes, and is called *Orenburgh gum.* It is wholly soluble in water. (*Lindley, Flor. Med.*)

Pistacia. See MASTICHE.

Pistacia Terebinthus. Willd. *Sp. Plant.* iv. 752; Woodv. *Med. Bot.* p. 29, t. 12. This is a small tree with numerous spreading branches, bearing alternate pinnate leaves, which consist of three or four pairs of ovate-lanceolate, entire, acute, smooth, and shining leaflets, with an odd one at the end. The male and female flowers are diœcious, small, and in branching racemes. This is a native of Barbary and Greece, and flourishes in the islands of Cyprus and Chio, the latter of which has given its name to the *Chian turpentine* obtained from the tree. A gall produced upon this plant by the puncture of an insect, has been used in Eastern Europe in pectoral affections.

We shall treat of the several varieties of turpentine under distinct heads.

1. White Turpentine.

Térébenthine de Boston, *Fr.*

The *common American* or *white turpentine* (*Terebinthina, U. S., Lond.*) is procured chiefly from *Pinus palustris*, partly also from *Pinus Tæda*, and perhaps some other species inhabiting the Southern States. In former times, large quantities were collected in New England; but the turpentine trees of that section of the Union are said to be nearly exhausted; and our commerce has been until recently almost exclusively supplied from North Carolina, and the south-eastern parts of Virginia. Within a few years, however, attention has been turned to the collection of this valuable product in Georgia and Florida; and there is no doubt that, in time, an abundant supply will be derived from the vast pine forests which occupy the southern portion of our country bordering on the Gulf of Mexico. The following is the process for obtaining the turpentine as described by Michaux. During the winter months, excavations of the capacity of about three pints are made in the trunk of the tree three or four inches from the ground. Into these the juice begins to flow about the middle of March, and continues to flow throughout the warm season, slowly at first, rapidly in the middle of summer, and more slowly again in the autumnal months. The liquid is removed from these excavations as they fill, and transferred into casks, where it gradually thickens, and

* The following is the formula usually followed. Take of essence of spruce *half a pint;* pimento bruised, ginger bruised, hops, each, *four ounces;* water, *three gallons.* Boil for five or ten minutes; then strain, and add of warm water *eleven gallons;* yeast *a pint;* molasses *six pints.* Mix, and allow the mixture to ferment for twenty-four hours.

ultimately acquires a soft solid consistence. Very large quantities are thus annually procured, sufficient not only to supply the whole consumption of this country, but also to furnish a valuable export.

White turpentine, as found in our shops, is yellowish-white, of a peculiar somewhat aromatic odour, and a warm, pungent, bitterish taste. It is somewhat translucent, and of a consistence which varies with the temperature. In the middle of summer it is almost semi-fluid and very adhesive, though brittle; in the winter it is often so firm and hard, as to be incapable of being made into pills without heat. Exposed to the air it ultimately becomes perfectly hard and dry. In the recent state it affords about seventeen per cent. of volatile oil. It is apt to contain small pieces of bark, wood, or other impurity.

2. Common European Turpentine.

Térébenthine de Bordeaux, Térébenthine commune, *Fr.;* Gemeiner Terpentin, *Germ.;* Trementina comune, *Ital.;* Trementina comun, *Span.*

This is the *Terebinthina Vulgaris* of the former London Pharmacopœia. It is furnished by several species of pine; but chiefly by *P. sylvestris* and *P. maritima*. From the latter tree it is obtained largely in the maritime districts of the South-west of France, especially in the department of the Landes, and is exported from Bordeaux. Hence it is called in commerce *Bordeaux turpentine*. The process for procuring it consists simply in making incisions into the trunk, or removing portions of the bark, and receiving the juice which flows out in small troughs, or in holes dug at the foot of the tree. It is purified by heating, and filtering it through straw, or by exposing it to the sun in a barrel, through holes in the bottom of which the melted turpentine escapes. Thus prepared, it is whitish, turbid, thickish, and separates, upon standing, into two parts, one liquid and transparent, the other of a consistence and appearance like those of thickened honey. As found in European commerce it often consists wholly of this latter portion. It speedily hardens upon exposure to the air in thin layers. The most liquid specimens are completely solidified by the addition of one part of magnesia to thirty-two of the turpentine. (Guibourt, *Journ. de Pharm.*, xxv. 499.) It is scarcely ever given internally, but furnishes large quantities of oil of turpentine and resin. We do not import it into this country. The substance which the French call *galipot* or *barras*, is that portion of the turpentine which concretes upon the trunk of the tree when wounded, and is removed during the winter. (*Thenard.*) This, when purified by melting with water and straining, takes the name of *yellow* or *white pitch*, or *Burgundy pitch*. When turpentine has been deprived of its oil by distillation, the resin which remains is called *rosin*, and sometimes *colophony*, from the Ionian city of that name, where it was formerly prepared. It is the resin (*resina*) of the Dublin College, and is sometimes called yellow resin (*resina flava*). White resin (*resina alba*) is prepared by incorporating this, while in fusion, with a certain proportion of water. Tar (*pix liquida*) is the turpentine extracted from the wood by a slow combustion, and chemically altered by the heat. Common pitch (*pix*, *pix nigra*, or *resina nigra*) is the solid residue left after the evaporation by boiling of the liquid parts of tar.

3. Canada Turpentine.

Canada balsam, Balsam of fir; Baume de Canada, *Fr.;* Canadischer Balsam, Canadischer Terpentin, *Germ.;* Trementina del Canada, *Ital.*

This is the product of *Abies balsamea*, and is collected in Canada and the State of Maine. It is procured by breaking the vesicles which naturally form upon the trunk and branches, and receiving their liquid contents in a bottle. When fresh, it is colourless or slightly yellowish, transparent, of the consistence

of thin honey, very tenacious, of a strong, agreeable odour, and a bitterish, somewhat acrid taste. By time and exposure it becomes thicker and more yellow, and at last assumes a solid consistence. It is usually brought into market in bottles, and is kept in the shops under the name of *Canada balsam* or *balsam of fir*. In Europe, it is sometimes called *balm of Gilead*, from its supposed resemblance to that celebrated medicine. The term *balsam*, as at present understood, is improperly applied to it; as it contains no benzoic or cinnamic acid, and is in fact a true turpentine, consisting chiefly of resin and volatile oil. Bonastre obtained from 100 parts of Canada turpentine, 18·6 parts of volatile oil, 40·0 of resin easily dissolved by alcohol, 33·4 of sub-resin of difficult solubility in that fluid, 4·0 of caoutchouc similar to sub-resin, and 4·9 of bitter extractive and salts, besides traces of acetic acid. There is reason to believe that *Strasburg turpentine* is sometimes sold for it in the shops.

4. Venice Turpentine.

Térébenthine de mélèze, Térébenthine de Venise, *Fr.;* Venetianischer Terpentin, *Germ.;* Trementina di Venezia, *Ital.;* Trementina de Venecia, *Span.*

This turpentine received its name from the circumstance that it was formerly an extensive article of Venetian commerce. It is procured in Switzerland, and the French province of Dauphiny, from the *Larix Europæa* or larch, which grows abundantly upon the Alps and the Jura mountains. The peasants bore holes into the trunk about two feet from the ground, and conduct the juice by means of wooden gutters into small tubs, placed at a convenient distance. It is afterwards purified by filtration through a leather sieve. Genuine Venice turpentine is a viscid liquid, of the consistence of honey, flowing with difficulty, cloudy or imperfectly transparent, of a yellowish or slightly greenish colour, a strong not disagreeable odour, and a warm bitterish and very acrid taste. It does not readily concrete on exposure, is not solidified by one-sixteenth of magnesia, and is entirely soluble in alcohol. (Guibourt, *Journ. de Pharm.*, xxv. 500.) What is sold under the name of Venice turpentine in our shops, is usually quite brown, and is said to be a factitious substance, prepared by dissolving rosin in oil of turpentine. Dr. A. T. Thomson states that much of the Venice turpentine of the shops of London is obtained from America. It is probably the same preparation as that which passes under the name in this country.

5. Chian Turpentine.

Térébenthine de Chio, *Fr.;* Cyprischer Terpentin, *Germ.;* Trementina Cipria, *Ital.*

This variety of turpentine is collected chiefly in the island of Chio or Scio, by incisions made during the summer in the bark of *Pistacia Terebinthus*. The juice, flowing from the wounds, falls upon smooth stones placed at the foot of the tree, from which it is scraped with small sticks, and allowed to drop into bottles. The annual product of each tree is very small; and the turpentine, therefore, commands a high price even in the place where it is procured. Very little of it reaches this country. It is said to be frequently adulterated with the other turpentines. It is a thick, tenacious liquid, of a greenish-yellow colour, a peculiar penetrating odour more agreeable than that of the other substances of the same class, and a mild taste without bitterness or acrimony. It leaves a glutinous residue when treated with strong alcohol. (*Guibourt.*) On exposure to the air it speedily thickens, and ultimately becomes concrete and hard, in consequence of the loss of its volatile oil.

Besides the turpentines mentioned, various others are noticed in books on materia medica, though not found in the shops of this country. There are the *Strasburg turpentine*, much used in France, and obtained from the *Abies Picea*

(*Abies pectinata* of De Candolle), or European silver fir, which grows on the mountains of Switzerland and Germany, and bears a close resemblance, as well in its appearance as its product, to the *Abies balsamea* of Canada;* the *Damarra turpentine*, which speedily concretes into a very hard resin, and is derived from the *Pinus Damarra* of Lambert, the *Agathis Damarra* of Richard, growing in the East India islands; and the *Dombeya turpentine*, a glutinous, milky-looking fluid, of a strong odour and taste, derived from *Dombeya excelsa*, the *Araucaria Dombeyi* of Richard, which inhabits Chili, and is said to be identical with the Norfolk Island pine. These, with one or two other turpentines scarcely known, or having a doubtful claim to the title, are all that belong properly to this class of vegetable products.

General Properties. The turpentines resemble each other in odour and taste, though distinguished by shades of difference. Liquid at first, they become thick, and gradually solid by exposure, in consequence partly of the volatilization, partly of the oxidation of their essential oil. They are rendered more liquid or softened by heat, and at a high temperature take fire, burning with a white flame and much smoke. Water extracts only a minute proportion of their volatile oil. They are almost wholly soluble in alcohol and ether, and readily unite with the fixed oils. They yield by distillation a volatile oil, well known as the *oil of turpentine*, and leave a residue consisting exclusively of resin. (See *Oleum Terebinthinæ* and *Resina.*) A minute proportion of succinic acid passes over with the oil. From the experiments of M. Faure, of Bordeaux, it appears that some of the liquid turpentines, like copaiba, may be solidified by the addition of magnesia (*Journ. de Chim. Méd.*, 1830, p. 94); and, according to M. Thierry, the same result is obtained by the addition of one part of hydrate of lime to thirty-two parts of the common European turpentine. (*Journ. de Pharm.*, 3e *sér.*, i. 315.)

Medical Properties and Uses. The effects of the turpentines upon the system are dependent entirely on their volatile oil. They are stimulant, diuretic, anthelmintic, and in large doses laxative. When taken internally, or applied to the skin, they communicate a violet odour to the urine, and, if continued for some time, produce an irritation of the mucous membrane of the urinary passages, amounting frequently to strangury. The last effect is less apt to be experienced when they operate upon the bowels. Externally applied they act as rubefacients. Their medical virtues were known to the ancients. At present they are less used than formerly, having been superseded by their volatile oil. They are, however, occasionally prescribed in leucorrhœa, gleet, and other chronic diseases of the urinary passages; in piles and chronic inflammation or ulceration of the bowels; in chronic catarrhal affections; and in various forms of rheumatism, especially sciatica and lumbago. The white turpentine is usually employed in this country.

They may be given in the shape of pill made with powdered liquorice root; in emulsion with gum Arabic or yolk of egg, loaf sugar, and water; or in electuary formed with sugar or honey. Their dose is from a scruple to a drachm. In the quantity of half an ounce or an ounce, triturated with the yolk of an egg, and mixed with half a pint of mucilaginous liquid, they form an excellent injection in cases of ascarides, and of constipation attended with flatulence.

* This turpentine is described by Guibourt as being nearly as liquid as olive oil, at first turbid and whitish, but becoming by filtration or long standing transparent and almost colourless. Its odour is very agreeable, analogous to that of the citron, and its taste moderately acrid and bitter. It dries quickly in the air, is solidified by a sixteenth of magnesia, and is not entirely soluble in alcohol. It is procured, like the Canada turpentine, by incisions into the vesicles which form upon the surface of the tree, beneath the outer bark. According to Guibourt, this is the true *Venice turpentine*, while that described in the text, and generally recognised by authors as Venice turpentine, is in fact the *Strasburg.* (See *Journ. de Pharm.*, xxv. 487.)—*Note to the eighth edition.*

The vapour of turpentine, employed as a vapour-bath, has recently been highly recommended in the treatment of obstinate chronic rheumatism. According to M. A. Chevandier, it is borne well for about twenty-five minutes, at a temperature of from 140° to 160° F., producing acceleration of the pulse, and copious sweating, sometimes accompanied with a confluent eruption. (*Arch. Gén.*, 4e *sér.*, xxviii. 80.)

TESTA. *U. S.*

Oyster-shell.

The shells of Ostrea edulis. *U. S.*

Ecailles des huitres, *Fr.;* Austerschalen, *Germ.;* Gusci della ostriche, *Ital.;* Cascaras, *Span.*

The common oyster is the *Ostrea edulis* of naturalists, an animal belonging to the class *Vermes*, order *Testacea*. It is found in many parts of the world, and is particularly abundant on our own coast, and in the bays of our large rivers. It consists of a soft pulpy portion, comprising the vital organs of the animal, enclosed in a hard bivalve shell, of the nature of mother-of-pearl. The flesh of the oyster forms a very digestible and nutritious article of food, particularly suited to convalescents; but the shell only is officinal.

Properties. Oyster-shells are too familiarly known to require description. They are made up, like other mother-of-pearl shells, of alternate layers of earthy matter, and of animal matter of the nature of coagulated albumen. According to the analysis of Bucholz and Brandes, their exact constituents are carbonate of lime 98·6, phosphate of lime 1·2, animal matter 0·5, alumina (accidental) 0·2=100·5. Thus it appears that the animal matter is present in but small amount. When calcined or burnt, the animal matter and carbonic acid are dissipated, and the shells are converted into a species of lime, called *oyster-shell lime.*

Crabstones, called crabs' eyes, and crabs' claws are both forms of carbonate of lime, resembling oyster-shell in containing a small proportion of animal matter. They were formerly officinal in the Edinburgh Pharmacopœia, but were very properly omitted on the last revision of that work. They will be noticed in the Appendix.

Pharmaceutical Uses. Oyster-shells require to be reduced to an impalpable powder, before they are fit for medicinal employment; and their preparation in this way constitutes their sole pharmaceutical use. When thus prepared they form *Testa Præparata*, under which head their medicinal properties will be noticed.

TORMENTILLA. *U. S. Secondary, Lond., Ed.*

Tormentil.

The root of Potentilla Tormentilla. *U. S., Ed.* The rhizoma. *Lond.*

Tormentille, *Fr.;* Tormentillwurzel, *Germ.;* Tormentilla, *Ital.;* Tormentila, *Span.*

POTENTILLA. *Sex. Syst.* Icosandria Polygynia.—*Nat. Ord.* Rosaceæ.

Gen. Ch. Calyx with a concave tube, a four or five-cleft limb, and four or five bractlets. *Petals* four or five. *Stamens* numerous. *Carpels* numerous, with a lateral style, on a procumbent, persistent, capitate, juiceless receptacle. *Seed* appended. Herbs or undershrubs, with compound leaves, stipules adnate to the petiole, and white, yellow, rarely red flowers. (*De Candolle.*)

Potentilla Tormentilla. Sibthorp. *Fl. Ox.* 162; Lindley, *Flor. Med.* 225.—*Tormentilla erecta.* Willd. *Sp. Plant.* ii. 1112; Woodv. *Med. Bot.* p. 503, t. 181.—*T. officinalis.* Smith, *Flor. Brit.* The tormentil, or *septfoil*, is a small perennial plant, very common throughout Europe. The stems, which rise about six or eight inches in height from a woody root, are slender, more or less erect, branching towards the top, and furnished with sessile leaves, which on the stalk usually consist of seven, on the branches of five, digitate, elliptical, villous, deeply serrated leaflets, three of which are larger than the others. The flowers are small, yellow, and solitary upon axillary peduncles. All parts of the plant are astringent, especially the root, which is the part employed. It is gathered in spring.

Properties. The root of tormentil is cylindrical or roundish, rather larger above than at the lower extremity, an inch or two in length, about as thick as the finger, knotty, sometimes contorted, brown or blackish externally, and reddish within. It has a slight aromatic odour, and a very astringent taste. Tannin is an abundant constituent. There is also a red colouring principle, soluble in alcohol, but insoluble in water. Besides these ingredients Meissner found resin, cerin, myricin, gummy extractive, gum, extractive, lignin, water, and a trace of volatile oil. The root is said to be used for tanning leather in the Orkneys and Western Islands of Scotland, and for staining leather red by the Laplanders. It yields all its medical virtues to boiling water.

Medical Properties and Uses. Tormentil is a simple and powerful astringent, applicable to all cases of disease in which this class of medicines is indicated. We seldom, however, employ it in this country, having indigenous plants of equal virtue. It may be given in substance, decoction, or extract. The dose of the powder is from thirty grains to a drachm.

TOXICODENDRON. *U. S. Secondary.*

Poison-oak.

The leaves of Rhus Toxicodendron. *U. S.*

Sumach vénéneux, *Fr.;* Gift-Sumach, *Germ.;* Albero del veleno, *Ital.*

RHUS. See RHUS GLABRUM.

Admitting, as appears generally to be done at present, that *Rhus Toxicodendron* and *Rhus radicans* of Linnæus are mere varieties of the same plant, there are three indigenous species of Rhus which possess poisonous properties—the one above mentioned, *R. vernix*, commonly known by the name of *swamp sumach* or *poison sumach*, and *R. pumilum* of the Southern States. Though the first only is designated in the Pharmacopœia, we shall briefly describe the three species; as their medical effects are probably similar, and their operation upon the system such that the plants should be known to every practitioner.

1. *Rhus radicans.* Willd. *Sp. Plant.* i. 1481; Bigelow, *Am. Med. Bot.* iii. 17.—*R. Toxicodendron.* Pursh, *Fl. Am. Sept.* p. 205. Though Elliott and Nuttall consider *R. radicans* and *R. Toxicodendron* as distinct species, the weight of botanical authority is on the other side, and Bigelow declares that he has "frequently observed individual shoots from the same stock, having the characters of both varieties." The difference, however, in their appearance is sufficiently striking to have led to the adoption of different common names, R. radicans being usually called *poison vine*, and R. Toxicodendron, *poison oak*. The former has a climbing stem, rising to a great height upon trees, rocks, and other objects, to which it adheres by strong rooting fibres, which it throws out from its sides. The leaves, which stand upon long footstalks, are ternate, with broad-ovate or rhomboidal, acute leaflets, smooth and shining on both sides, sometimes slightly hairy

on the veins beneath, entire, or irregularly lobed and toothed. The flowers are small, greenish-white, dicœcious, and grow in lateral, usually axillary panicles, or compound racemes. The male flowers have five stamens, and the rudiments of a style; the female, which are of only half the size and on a different plant, have abortive stamens, and a short erect style, standing on a roundish germ, and terminating in three stigmas. The fruit consists of roundish, pale-green or whitish berries.

R. Toxicodendron, or poison-oak, has the form of a shrub from one to three feet high, with leaflets angularly indented, and pubescent beneath. But this character of the foliage is probably not constant; and the stunted growth may be owing to peculiarities of situation. Dr. Bigelow states that the young plants of R. radicans do not put forth rooting fibres until they are several years old, and that they are influenced in this respect by the contiguity of supporting objects.

This species of Rhus grows in woods, fields, and along fences from Canada to Georgia. It flowers in June and July. When wounded, it emits a milky juice, which becomes black on exposure to the air, and leaves upon linen or other cloth a stain, which cannot afterwards be removed by washing with soap and water, or by alcohol either hot or cold, but deepens by age. It has been proposed as an indelible ink. Ether dissolves it.

The juice applied to the skin frequently produces inflammation and vesication; and the same poisonous property is possessed by a volatile principle which escapes from the plant itself, and produces in certain persons when they come into its vicinity an exceedingly troublesome erysipelatous affection, particularly of the face. Itching, redness, a sense of burning, tumefaction, vesication, and ultimate desquamation, are some of the attendants of this poisonous action. The swelling of the face is sometimes so great as almost entirely to obliterate the features. The effects are experienced soon after exposure, and usually begin to decline within a week. A light cooling regimen, with saline purgatives, and the local use of cold lead-water, are the best remedies. All persons are not equally liable to the affection, and the great majority are wholly insusceptible of it from any ordinary exposure.

2. *Rhus vernix.* Willd. *Sp. Plant.* i. 1479; Bigelow, *Am. Med. Bot.* i. 96. The *swamp sumach* is a beautiful shrub or small tree, usually ten or fifteen feet high, but sometimes rising thirty feet. The bark of the trunk is dark-gray, of the branches lighter, of the extreme twigs and petioles beautifully red. The leaves are pinnate, with four or five pairs of opposite leaflets, and an odd terminal one. These are oblong or oval, entire or slightly sinuated, acuminate, smooth, and, except the one at the end, nearly sessile. The flowers, as in the preceding species, are dicœcious. They are very small, greenish, and arranged in loose axillary panicles. The berries are small, roundish, and greenish-white.

The tree grows in swamps and low grounds, from Canada to Carolina, and flowers in June and July. It is thought to be identical with a species of Rhus which grows in Japan, and furnishes a fine black varnish, much used in that country. Dr. Bigelow found that the opaque whitish juice which exudes from our native plant when wounded, and which becomes permanently black on exposure, may be made to afford a brilliant, glossy, durable varnish, by boiling it sufficiently before applying it.

Rhus vernix produces, much more powerfully than *R. radicans*, the poisonous effects already described. Persons coming within its influence are much more apt to be affected with the poison, and generally suffer more severely. The whole body is sometimes enormously swollen, and the patient for many days scarcely able to move; but the complaint almost always spontaneously subsides without destroying life. As in the former instance, the susceptibility to the influence of the poison is exceedingly various, and some persons handle the plant with perfect impunity.

3. *Rhus pumilum.* Michaux, *Flor. Americ.* i. 182. This is a southern species, growing in upper Carolina, and not more than a foot in height. It is characterized by its pubescent branches and petioles; its pinnate leaves, with many pairs of oval, nearly acuminate, incised-dentate leaflets, downy beneath; and by its silky fruit. According to Pursh, it is the most poisonous of the genus.

It is probable that all parts of Rhus radicans (R. Toxicodendron) are possessed of active properties; but the leaves only are directed in the Pharmacopœia, under the title of Toxicodendron. These are inodorous, have a mawkish acrid taste, and yield their virtues to water. The presence of tannic and gallic acids has been detected in them.

Medical Properties and Uses. These leaves appear to be stimulant and narcotic, producing when swallowed more or less irritation of the stomach and bowels, and promoting the secretory function of the skin and kidneys. Orfila found them to act in the manner of the acrid poisons, and to produce a stupefying effect upon the nervous system. They were successfully used by Du Fresnoy, in France, in the cure of obstinate cutaneous diseases. Dr. Anderson, of Hull, in England, effected cures with the medicine in several cases of palsy. A sense of heat and pricking, with irregular twitchings, was excited by it in the affected parts. Dr. Horsfield, and other physicians of this country, have used it in consumption and dropsy, but with little success.

The dose of the leaves recommended by Dr. Anderson was half a grain or a grain three times a day; but this is much too small. Dr. Duncan gave them in larger doses, with little other than a laxative effect. Dr. Horsfield administered a teacupful of the strong infusion without disadvantage. In France, the extract is recommended in doses of fifteen or twenty grains, repeated two or three times a day, and gradually increased to one or two drachms. Some of Du Fresnoy's patients took an ounce without effect. The probability is, that the active principle is volatile, and that the extract is less efficient than the leaves themselves. The risk of experiencing the poisonous effects of the plant upon the system, will probably prevent its extensive employment as a remedy, unless it should prove much more useful than the trials hitherto made give us reason to expect.

Gen. Ch. Legume two-celled, more or less gibbous, with the lower suture turned inwards. *Carina* blunt. *Loudon's Encyc. of Plants.*

Numerous species belonging to this genus yield a gummy matter having the properties of tragacanth. The drug known in commerce by that name was at first erroneously supposed to be obtained from *A. Tragacantha* of Linnæus (*A. massiliensis* of Lamarck), which grows in the South of Europe and North of Africa, and is now said to yield no gum. It was afterwards ascribed, on the authority of Tournefort, to a species (*A. Creticus* of Lamarck) which grows in Crete and Ionia, and, on that of Olivier, to *A. verus*, which inhabits Asia Minor, Armenia, and Northern Persia. Labillardière described a species by the name of *A. gummifer*, which he found growing on Mount Libanus in Syria, and from which tragacanth

exudes, though not that of commerce. Sieber denies that any one of these species yields the officinal tragacanth, which he ascribes to *A. aristatus* growing in Anatolia, especially upon Mount Ida, where the gum is most abundantly collected. This plant, however, is not the *A. aristatus* of Villars, which, according to Sibthorp, furnishes tragacanth in Greece. (*Merat* and *De Lens.*) Professor Lindley received two specimens of plants, said to be those which furnish tragacanth in Turkistan, one of which proved to be *A. gummifer* of Labillardière, which was said to yield a white variety, and the other a new species which he called *A. strobiliferus*, and which was said to yield a red and inferior product. The fact seems to be, that the commercial drug is collected from various sources; and it is affirmed that all the species of Astragalus with thorny petioles are capable of producing it. These form a natural group, and so closely resemble each other that botanists have found some difficulty in distinguishing them. As *A. verus* is designated in the Pharmacopœia of the United States, and that of the London College, we shall briefly describe it.

Astragalus verus. Olivier, *Voy. dans l'Empire Ottoman*, v. 342, pl. 44. This is a small shrub, not more than two or three feet high, with a stem an inch in thickness, and numerous very closely crowded branches, covered with imbricated scales, and spines which are the remains of former petioles. The leaves, which are little more than half an inch long, consist of several pairs of opposite, villous, stiff, pointed leaflets, with a midrib terminating in a sharp yellowish point. The flowers are papilionaceous, small, yellow, axillary, aggregate, and furnished with cottony bractes. This species yields the gum collected in Persia, and thence transmitted southward to India through Bagdad and Bassora, northward to Russia, and westward to Aleppo.

Tragacanth exudes spontaneously during the summer from the stems and branches, hardening as it exudes, and assuming various forms according to the greater or less abundance of the juice.

Properties. It is in tortuous vermicular filaments, rounded or flattened, rolled up or extended, of a whitish or yellowish-white colour, somewhat translucent, resembling horn in appearance. Sometimes the pieces are irregularly oblong or roundish, and of a slightly reddish colour. It is hard and more or less fragile, but difficult of pulverization, unless exposed to a freezing temperature, or thoroughly dried, and powdered in a heated mortar. The powder is very fine and white. Tragacanth has no smell and very little taste. Its sp. gr. is 1·384. Introduced into water it absorbs a certain proportion of that liquid, swells very much, and forms a soft adhesive paste, but does not dissolve. If agitated with an additional quantity of water, this paste forms a uniform mixture; but in the course of one or two days the greater part separates, and is deposited, leaving a portion dissolved in the supernatant fluid. Tragacanth is wholly insoluble in alcohol. It appears to be composed of two different constituents, one soluble in water and resembling gum Arabic, the other swelling in water, but not dissolving. The former is said to differ from gum Arabic in affording no precipitate with silicate of potassa or sesquichloride of iron. (*Pereira's Mat. Med.*) The latter, which, according to Bucholz, constitutes 43 per cent. of tragacanth, is ranked by some among the peculiar proximate principles with the title of *tragacanthin*. It is probably identical with *bassorin*. It has the property of becoming blue with iodine, which is not the case with bassorin; but this property is ascribed to the presence of a small quantity of insoluble starch. According to M. Guerin, 100 parts of tragacanth contain 53·3 parts of arabin or pure gum, 33·1 of bassorin and insoluble starch, and 11·1 of water, and yield when burned 2 5 parts of ashes. To separate the soluble entirely from the insoluble part, requires agitation with separate portions of water, which are to be decanted and filtered; and the process is to be continued till water ceases to dissolve anything.

Berzelius considers tragacanth as a variety of mucilage. (See *Linum.*) Examined by Dr. Kützing, by means of the microscope, it was found to consist of organized cells, having thick walls sometimes of several concentric layers, and filled with starch granules. (See *Am. Journ. of Pharm.*, xxv. 37.)

Medical Properties and Uses. Tragacanth is demulcent, but, on account of its difficult solubility, is not often given internally. The great viscidity which it imparts to water, renders it useful for the suspension of heavy insoluble powders; and it is also employed in pharmacy to impart consistence to troches, for which it answers better than gum Arabic.

TRIOSTEUM. *U. S. Secondary.*

Fever-root.

The root of Triosteum perfoliatum. *U. S.*

Triosteum. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Caprifoliaceæ.

Gen. Ch. Calyx five-cleft, persistent, nearly the length of the corolla; segments linear, acute. *Corolla* tubular, five-lobed, sub-equal; base, nectariferous, gibbous. *Stigma* somewhat five-lobed, capitate. *Berry* three-celled, three-seeded, crowned with the calyx. *Nuttall.*

Triosteum perfoliatum. Willd. *Sp. Plant.* i. 990; Bigelow, *Am. Med. Bot.* i. 90; Barton, *Med. Bot.* i. 59. This plant is indigenous and perennial. Several stems usually rise from the same root. They are simple, erect, round, hairy, fistulous, herbaceous, and from one to four feet high. The leaves are opposite, large, mostly connate, oval, acuminate, entire, abruptly narrowed at the base, and pubescent on their under surface. The flowers are of a dull-purple colour, axillary, sessile, rarely solitary, sometimes in pairs, generally in triplets or five together in the form of whorls. The germ is inferior, and the style projects beyond the corolla, into the tube of which the stamens are inserted. The berry is oval and of a deep-orange colour, and contains three hard, bony seeds.

Fever-root, fever-wort, or *wild ipecac,* as this plant is variously called, though not very abundant, is found in most parts of the United States, preferring a limestone soil and shady situations. Its flowers appear in June. The whole plant has a bitter taste; but the root is most active, and is the only officinal part.

It is horizontal, long, about three-quarters of an inch in diameter, thicker and tuberculated near the origin of the stem, of a yellowish or brownish colour externally, whitish within, and furnished with fibres which may be considered as branches of the main root. When dry it is brittle and easily pulverized. It has a sickening odour, and a bitter nauseous taste. Both water and alcohol take up its active properties, which are retained in the extract.

Medical Properties and Uses. Fever-root is cathartic, and in large doses emetic. The late Professor Barton observed it also to produce a diuretic effect. The bark of the root is the part which has been usually employed. In the quantity of twenty or thirty grains it ordinarily acts upon the bowels; and may be given alone or in combination with calomel at the commencement of fevers. The extract may be given in half the dose. W.

ULMUS. *Lond.*

Elm Bark.

Ulmus campestris. The interior bark. *Lond.*

Ecorce d'orme, *Fr.;* Ulmenrinde, *Germ.;* Scorza del olma, *Ital.:* Corteza de olmo, *Span.*

Ulmus. *Sex. Syst.* Pentandria Digynia.—*Nat. Ord.* Ulmaceæ.

Gen. Ch. Calyx five-cleft. *Corolla* none. *Capsule* (*samara*) compressed membranaceous. *Willd.*

Ulmus campestris. Willd. *Sp. Plant.* i. 1324; Woodv. *Med. Bot.* p. 710, t. 242. This species of elm is characterized by its doubly serrate leaves, unequal at their base, by its nearly sessile, clustered, pentandrous flowers, and its smooth fruit. It is a large tree, with strong spreading branches, and a rough, cracked bark. It is a native of Europe, where the wood is highly esteemed for certain purposes in the arts.

The inner bark of its young branches, which is the officinal portion, is thin, tough, of a brownish-yellow colour, inodorous, and of a mucilaginous, bitterish, and very slightly astringent taste. It imparts to water its taste and mucilaginous properties. The tincture of iodine indicates the presence of starch, and Davy found somewhat more than two per cent. of tannin. A peculiar vegetable principle called *ulmin* or *ulmic acid*, now believed to be a constituent of most barks, was first discovered in the matter which spontaneously exudes from the bark of the European elm. It is a dark-brown almost black substance, without smell or taste, insoluble in cold water, sparingly soluble in boiling water which it colours yellowish-brown, soluble in alcohol, and readily dissolved by alkaline solutions.

Medical Properties and Uses. The bark of the European elm is demulcent, and very feebly tonic and astringent, and is said also to be diuretic. It has been recommended in cutaneous affections of the leprous character. Dr. Sigmond speaks in strong terms of its efficacy in all the varieties of lepra, in lichenous eruptions, and in tinea capitis, employed both internally and externally. (*Medico-Bot. Trans.*, i. 169.) It is usually given in the form of decoction, and in chronic cases must be long continued to produce beneficial results.

ULMUS. *U. S.*

Slippery Elm Bark.

The inner bark of Ulmus fulva. *U. S.*

Ulmus. See ULMUS. *Lond.*

Ulmus fulva. Michaux, *Flor. Americ.* i. 172. — *Ulmus rubra.* F. Andrew Michaux, *N. Am. Sylv.* iii. 89. The *slippery elm*, called also *red elm*, is a lofty tree, rising fifty or sixty feet in height, with a stem fifteen or twenty inches in diameter. The bark of the trunk is brown, that of the branches rough and whitish. The leaves are oblong-ovate, acuminate, nearly equal at the base, unequally serrate, pubescent and very rough on both sides, four or five inches in length by two or three in breadth, and supported on short footstalks. The buds, a fortnight before their development, are covered with a dense russet down. The flowers, which appear before the leaves, are sessile, and in clusters at the extremity of the young shoots. The bunches of flowers are surrounded by scales, which are downy like the buds. The calyx also is downy. There is no corolla. The stamens are five in number, short, and of a pale-rose colour. The fruit is a membranaceous capsule or samara, enclosing in the middle one round seed, destitute of fringe.

This species of elm is indigenous, growing in all parts of the United States north of Carolina, but most abundantly west of the Alleghany mountains. It flourishes in open, elevated situations, and requires a firm, dry soil. From the *white elm*, *U. Americana*, it is distinguished by its rough branches, its larger, thicker, and rougher leaves, its downy buds, and the character of its flowers and seeds. Its period of flowering is in April. The inner bark is the part used, and is brought to the shops separated from the epidermis.

It is in long, nearly flat pieces, from one to two lines in thickness, of a fibrous texture, a tawny colour which is reddish on the inner surface, a peculiar sweetish, not unpleasant odour, and a highly mucilaginous taste when chewed. By grinding, it is reduced to a light, grayish fawn-coloured powder. It abounds in mucilaginous matter, which it readily imparts to water. The mucilage is precipitated by solutions of acetate and subacetate of lead, but not by alcohol.

Much of the bark recently brought into the market is of inferior quality, imparting comparatively little mucilage to water. It has the characteristic odour of the genuine bark, but is much less fibrous and more brittle, breaking abruptly when bent, instead of being capable, like the better kind, of being folded lengthwise without breaking. To what this inferiority is owing, whether to difference in the species or the age, or to circumstances in the growth of the tree producing it, we are unable to determine.

Dr. C. W. Wright, of Cincinnati, in a communication to the *Western Lancet*, states that slippery elm bark has the property of preserving fatty substances from rancidity; a fact derived originally from the Indians, who prepared bears' fat by melting it with the bark, in the proportion of a drachm of the latter to a pound of the former, keeping them heated together for a few minutes, and then straining off the fat. Dr. Wright tried the same process with butter and lard, and found them to remain perfectly sweet for a long time. (*Am. Journ. of Pharm.*, xxiv. 180.)

Medical Properties and Uses. Slippery elm bark is an excellent demulcent, applicable to all cases in which this class of medicines is employed. It is especially recommended in dysentery, diarrhœa, and diseases of the urinary passages. Like the bark of the common European elm, it has been employed in cutaneous eruptions; but neither in these, nor in any other complaints, does it probably exert any greater powers than such as belong to the demulcents generally. Its mucilage is highly nutritious; and we are told that it has proved sufficient for the support of life in the absence of other food. The instance of a soldier is mentioned, who lived for ten days in the woods on this bark and sassafras; and the Indians are said to resort to it for nutriment in extreme emergencies.

It is usually employed as a drink in the form of infusion. (See *Infusum Ulmi.*) The powder may be used, stirred in hot water, with which it forms a mucilage, more or less thick according to the proportion added. The bark also serves as an emollient application in cases of external inflammation. For this purpose the powder may be formed into a poultice with hot water, or the bark itself may be applied, previously softened by boiling. Dr. McDowell, of Virginia, has recommended the use of slippery elm bark for the dilatation of fistulas and strictures. (*Med. Examiner*, i. 244, from the *West. Journ. of Med. and Phys. Sci.*)

VITIS. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Vitaceæ.

Gen. Ch. Petals cohering at the apex, withering. *Berry* five-seeded, superior. *Willd.*

Vitis vinifera. Willd. *Sp. Plant.* i. 1180; Woodv. *Med. Bot.* p. 144, t. 57. The vine is too well known to require description. This particular species is

distinguished by the character of its leaf, which is lobed, sinuated, and naked or downy. The leaves and tendrils are somewhat astringent, and were formerly used in diarrhœa, hemorrhages, and other morbid discharges. The juice which flows from the stem was also thought to be possessed of medicinal virtues, and the prejudice still lingers among the vulgar in some countries. The unripe fruit has a harsh sour taste, and yields by expression a very acid liquor, called *verjuice*, which was much esteemed by the ancients as a refreshing drink, when diluted with water. It contains malic and tartaric acids, and another called by some chemists *racemic acid*, by Berzelius *paratartaric acid*, from its resemblance to the tartaric, with which it agrees in composition, though differing from it in properties. The grape, when quite ripe, is among the most pleasant and grateful fruits brought upon the table, and is admirably adapted, by its refreshing properties, to febrile complaints. If largely taken, it proves diuretic and gently laxative. The ripe fruit differs from the unripe in containing more sugar and less acid, though never entirely destitute of the latter. The plant is supposed to have been derived originally from Asia; but it has been cultivated in Europe and Northern Africa from the remotest antiquity, and is now spread over all the temperate civilized regions of the globe. The fruit is exceedingly influenced by soil and climate, and the varieties which have resulted from culture or situation are innumerable. Those which yield the raisins of commerce are confined to the basin of the Mediterranean.

Raisins are prepared either by partially cutting the stalks of the bunches before the grapes are perfectly ripe, and allowing them to dry upon the vine; or by picking them in their mature state, and steeping them for a short time previously to desiccation in an alkaline ley. Those cured by the first method are most highly esteemed.

Several varieties of raisins are known in commerce. The best of those brought to this country are the *Malaga* raisins, imported from Spain. They are large and fleshy, of a purplish-brown colour, and sweet agreeable taste. Those produced in Calabria are similar. The *Smyrna* raisins are also large, but of a yellowish-brown colour, slightly musky odour, and less agreeable flavour. They are originally brought from the coast of Syria. The *Corinthian raisins*, or *currants* as they are commonly called in this country, are small, bluish-black, of a fatty appearance, with a vinous odour, and a sweet slightly tartish taste. Their name was derived from the city in the vicinity of which they were formerly cultivated. At present they are procured chiefly from Zante, Cephalonia, and the other Ionian Islands. In the older Pharmacopœias they are distinguished by the title of *uvæ passæ minores*.

Raisins contain a larger proportion of sugar than recent grapes. This principle, indeed, is often so abundant that it effloresces on the surface, or concretes in separate masses within the substance of the raisin. The *sugar of grapes* differs slightly from that of the cane, and is said to be identical with that produced by the action of sulphuric acid upon starch. It is less sweet than common sugar, less soluble in cold water, much less soluble in alcohol, and forms a syrup of less consistence.

Medical Properties and Uses. The chief medical use of raisins is to flavour demulcent beverages. Taken in substance they are gently laxative; but are also flatulent and difficult of digestion, and, when largely eaten, sometimes produce unpleasant effects, especially in children.

UVA URSI. *U. S., Lond., Ed., Dub.*

Uva Ursi.

The leaves of Arctostaphylos Uva Ursi. *U. S., Lond., Ed., Dub.*

Busserole, Raisin d'ours, *Fr.;* Bärentraube, *Germ.;* Corbezzolo, Uva Ursina, *Ital.;* Gayuba, *Span.*

Arctostaphylos. *Sex. Syst.* Decandria Monogynia.—*Nat. Ord.* Ericaceæ. *Gen. Ch. Drupe* with five distinct, one-seeded stones. *Corolla* urceolate, with a revolute limb. *Stamens* included. *Anthers* with two spurs at the back. (Lindley, *Med. and Æcon. Bot.*, 106.)

Arctostaphylos Uva Ursi. Sprengel, *Syst.* ii. 287; Carson, *Illust. of Med. Bot.* i. 61, pl. 52.—*Arbutus Uva Ursi.* Willd. *Sp. Plant.* ii. 618; Bigelow, *Am. Med. Bot.* i. 66. The *uva ursi*, or *bearberry*, is a low evergreen shrub, with trailing stems, the young branches of which rise obliquely upwards for a few inches. The leaves are scattered upon short petioles, obovate, acute at the base, entire, with a rounded margin, thick, coriaceous, smooth, shining, of a deep-green colour on their upper surface, paler and covered with a network of veins beneath. The flowers, which stand on short reflexed peduncles, are collected in small clusters at the ends of the branches. The calyx is small, five-parted, of a reddish colour, and persistent. The corolla is ovate or urceolate; reddish-white, or white with a red lip, transparent at the base, contracted at the mouth, and divided at the margin into five short reflexed segments. The stamens are ten, with short filaments and bifid anthers; the germ round, with a style longer than the stamens, and a simple stigma. The fruit is a small, round, depressed, smooth, glossy, red berry, containing an insipid mealy pulp, and five cohering seeds.

This humble but hardy shrub inhabits the northern latitudes of Europe, Asia, and America. It is also found in the lofty mountains of Southern Europe, such as the Pyrenees and the Alps; and, on the American continent, extends from Hudson's Bay as far southward as New Jersey, in some parts of which it grows in great abundance. It prefers a barren soil, flourishing on gravelly hills, and elevated sandy plains. The leaves are the only part used in medicine. They are imported from Europe; but are also collected within our own limits; and the market of Philadelphia is supplied to a considerable extent from New Jersey. They should be gathered in autumn, and the green leaves only selected.

In Europe the uva ursi is often adulterated with the leaves of *Vaccinium Vitis Idæa*, which are wholly destitute of its peculiar properties, and may be distinguished by their rounder shape, their revolute edges which are sometimes slightly toothed, and the appearance of their under surface, which is dotted, instead of being reticulated as in the genuine leaf. Leaves of the *Chimaphila umbellata* are sometimes found among the uva ursi as it exists in our markets. They may be readily detected by their greater length, their cuneiform-lanceolate shape, and their serrate edges.

The leaves of the uva ursi are inodorous when fresh, but acquire a smell not unlike that of hay when dried and powdered. Their taste is bitterish, strongly astringent, and ultimately sweetish. They afford a light-brown, greenish-yellow powder. Water extracts their active principles, which are also soluble in officinal alcohol. Among their ingredients are tannic and gallic acids, bitter extractive, resin, gum, fatty matter, a volatile oil, and salts of potassa and lime. The tannic acid is so abundant that the leaves are used for tanning in some parts of Russia. Neither this principle nor gallic acid exists in the leaves of the *Vaccinium Vitis Idæa*. A crystallizable principle was extracted from uva ursi by Mr. J. C. C. Hughes, by the following process. An aqueous extract of the leaves was treated with strong alcohol, and submitted for twenty-four hours to the action of purified

animal charcoal. The tincture was filtered and evaporated, and the residue redissolved in alcohol and treated with animal charcoal as before. After filtration, the liquid was allowed to evaporate spontaneously, and yielded colourless, transparent, needle-shaped crystals, soluble in alcohol, ether, and dilute acids, insoluble in the fixed and volatile oils, neutral to test-paper, and combustible. Its watery solution is precipitated by subacetate of lead and carbonate of potassa, but not by lime-water, or tincture of chloride of iron. One grain of it acted as a powerful diuretic. Mr. Hughes proposed for this substance the name of *ursin*. (*Am. Journ. of Pharm.*, xix. 90.) Kawalier obtained a crystalline substance, named *arbutin*, by precipitating the decoction with acetate of lead, filtering, treating the liquid with sulphuretted hydrogen, again filtering, evaporating to the consistence of syrup, and allowing the resulting product to stand for several days. This gradually assumed the form of a crystalline jelly, which, being placed upon linen so as to allow the mother liquor to drain off, and then pressed, yielded nearly colourless crystals, which were purified by solution in boiling water, and treatment with animal charcoal. Arbutin thus obtained is in long, acicular, colourless crystals, united in tufts, and of a bitter taste. It is soluble in water, alcohol, and ether, unchanged apparently by a heat of 212°, but fusible at a high temperature, without action on vegetable colours, and not precipitated by sesquisalts of iron, or by acetate or subacetate of lead. Its formula is $C_{32}H_{24}O_{21}$. (*Chem. Gaz.*, Feb. 15, 1853, p. 61.)

Medical Properties and Uses. Uva ursi is astringent and tonic, and is thought by some to have a specific direction to the urinary organs, for the complaints of which it is chiefly used. Others deny that it possesses any peculiar tendency of this kind, and ascribe all its effects to its astringent and tonic action. It alters the colour of the urine, and its astringent principle has been detected in that secretion. It probably, therefore, exerts a direct influence on the kidneys and urinary passages. Though known to the ancients, it had passed into almost entire neglect, till its use was revived by De Haen about the middle of the last century. It has acquired some reputation as an antilithic, and has undoubtedly been serviceable in gravel, partly, perhaps, by a direct action on the kidneys, partly by giving tone to the digestive organs, and preventing the accumulation of principles calculated to produce a secretion or precipitation of calculous matter. In chronic nephritis it is also a popular remedy, and is particularly recommended when there is reason to conjecture the existence of ulceration in the kidneys, bladder, or urinary passages. Diabetes, catarrh of the bladder, incontinence of urine, gleet, leucorrhœa, and menorrhagia, are also among the diseases in which it has occasionally proved serviceable; and testimony is not wanting to its beneficial effects in phthisis pulmonalis. Dr. E. G. Harris, of Fayette, Alabama, believes it to have the property of promoting uterine contraction, and has employed it with supposed advantage as a substitute for ergot in tedious labours. (*Med. Exam.*, N. S., ix. 727, from *South. Med. and Surg. Journ.*) The dose of the powder is from a scruple to a drachm, to be repeated three or four times a day; but the form of decoction is usually preferred. (See *Decoctum Uvæ Ursi.*)

VALERIANA. *Sex. Syst.* Triandria Monogynia.—*Nat. Ord.* Valerianaceæ.

Gen. Ch. Calyx very small, finally enlarged into a feathery pappus. *Corolla* monopetalous, five-lobed, regular, gibbous at the base. *Capsule* one-celled. (*Loudon's Encyc. of Plants.*) *Stamens* exserted, one, two, three, and four. (*Nuttall.*)

Valeriana officinalis. Willd. *Sp. Plant.* i. 177; Woodv. *Med. Bot.* p. 77, t. 32. The *officinal*, or *great wild valerian*, is a large handsome herbaceous plant, with a perennial root, and an erect, round, channeled stem, from two to four feet high, furnished with opposite pinnate leaves, and terminating in flowering branches. The leaves of the stem are attached by short broad sheaths, the radical leaves are larger and stand on long footstalks. In the former the leaflets are lanceolate and partially dentate, in the latter elliptical and deeply serrate. The flowers are small, white or rose-coloured, agreeably odorous, and disposed in terminal corymbs, interspersed with pear-shaped pointed bractes. The number of stamens is three. The fruit is a capsule containing one oblong-ovate, compressed seed.

The plant is a native of Europe, where it grows either in damp woods and meadows, or on dry elevated grounds. As found in these different situations, it presents characters so distinct as to have induced some botanists to make two varieties. Dufresne makes four, of which three prefer marshy situations. The variety which affects a dry soil (*sylvestris*, L. Ph.) is not more than two feet high, and is distinguished by its narrow leaves. It has been generally believed to be superior to the others in medicinal virtue; but, from experiments of A. Buchner, it appears that the dried roots of the variety which grows in low moist grounds are in no respect inferior, and that the general opinion to the contrary is a prejudice. (*Pharm. Cent. Blatt*, June 16, 1852, p. 429.)

The root, which is the officinal portion, is collected in spring before the stem begins to shoot, or in the autumn when the leaves decay. It should be dried quickly, and kept in a dry place. It consists of numerous long, slender, cylindrical fibres, issuing from a tuberculated head or rhizoma. As brought to this country it frequently has portions of the stem attached. The English is superior to that brought from the continent of Europe. Within a few years valerian of very good quality has been produced by the Shakers at Enfield, New Hampshire. (Gardener, *New York Journ. of Med.*, N. S., iv. 190.) From our own observation, we know that the plant grows luxuriantly under culture in this country.

Properties. The colour of the root is externally yellowish or brown, internally white. The powder is yellowish-gray. The odour, which in the fresh root is slight, in the dried is strong and highly characteristic, and, though rather pleasant to many persons, is very disagreeable to others. Cats are said to be strongly attracted by it. The taste is at first sweetish, afterwards bitter and aromatic. Valerian yields its active properties to water and alcohol. Trommsdorff found it to consist of 1·2 parts of volatile oil; 12·5 of a peculiar extractive matter, soluble in water, insoluble in ether and alcohol, and precipitated by metallic solutions; 18·75 of gum; 6·25 of a soft odorous resin; and 63 of lignin. Runge found in it a peculiar fixed acid, which produced with bases white salts, becoming green on exposure to the air. (*Chem. Gaz.*, No. 170, p. 452.) Of these constituents the most important is the volatile oil, in which the virtues of the root chiefly reside. It is of a pale-greenish colour, of the sp. gr. 0·934, with a pungent odour of valerian, and an aromatic taste. It becomes yellow and viscid by exposure. Trommsdorff ascertained that it contains a peculiar volatile acid, upon which the name of *valerianic acid* or *valeric acid* has been conferred. This, when separated from the oil, is a colourless liquid, of an oleaginous consistence, having an odour analogous to that of valerian, and a very strong, sour, disagreeable taste. It is soluble in thirty parts of water, and in all proportions in ether and alcohol. It combines with salifiable bases, forming soluble salts, which retain, in a diminished degree, the odour of the acid. (*Journ. de Pharm.*, xx. 316.) From the experiments of MM. Cozzi and Thirault, it would appear that the acid does not pre-

exist in the root, but results from the oxidation of the volatile oil. (*Ibid.*, 3*e sér.*, xii. 162.) Valerianic acid is obtained by distilling the impure oil from carbonate of magnesia, decomposing by sulphuric acid the valerianate of magnesia which remains, and again distilling. M. Rabourdin, of Orleans, believing that a large proportion of the valerianic acid remains fixed in the root by union with a base, and does not come over by distillation alone, procures it by adding sulphuric acid to the root with a sufficient quantity of water, distilling, separating the oil, saturating the liquor with carbonate of soda, evaporating, adding a slight excess of sulphuric acid, and again distilling. (*Ibid.*, vi. 310.) The following process by Messrs. T. and H. Smith, of Edinburgh, avoids the inconvenience of distilling so bulky a root as valerian, while it answers the same purpose as that of M. Rabourdin. Boil the root for three or four hours with rather more than its bulk of water, in which an ounce of carbonate of soda is dissolved for every pound of the root, replacing the water as it evaporates. Express strongly, and boil the residuum twice with the same quantity of water, expressing each time as before. Mix the liquids, add two fluidrachms of strong sulphuric acid for every pound of the root, and distil till three-fourths of the liquid have passed over. Neutralize this with carbonate of soda, concentrate the liquid, decompose the valerianate of soda contained in it by sulphuric acid, and separate the valerianic acid now set free, either by a separatory, or by distillation. (See *Am. Journ. of Pharm.*, xvii. 253.) A similar process was also proposed by Prof. Procter, of Philadelphia. (*Ibid.*, xvii. 3.) M. J. Lefort proposes to obtain the acid by the rapid oxidation of the volatile oil. His plan is to distil 100 parts of the root with 500 of water, 10 of sulphuric acid, and 6 of bichromate of potassa. In this way he has procured a larger proportion of acid than by any other process. (*Journ. de Pharm.*, 3*e sér.*, x. 194.)*

The roots of the *Valeriana Phu* and *V. dioica* are said to be sometimes mingled with those of the officinal plant; but the adulteration is attended with no serious consequences; as, though much weaker than the genuine valerian, they possess similar properties. The same cannot be said of the roots of several of the *Ranunculaceæ*, which, according to Ebermayer, are sometimes fraudulently substituted in Germany. They may be readily detected by their want of the peculiar odour of the officinal root.

Medical Properties and Uses. Valerian is gently stimulant, with an especial direction to the nervous system, but without narcotic effect. In large doses it produces a sense of heaviness and dull pain in the head, with various other effects indicating nervous disturbance. It is useful in cases of irregular nervous action, when not connected with inflammation, or an excited condition of the system. Among the complaints in which it has been particularly recommended are hysteria, hypochondriasis, epilepsy, hemicrania, and low forms of fever attended with restlessness, morbid vigilance, or other nervous disorder. It has also been used in intermittents, combined with Peruvian bark. At best, however, it is an uncertain remedy. It may be given in powder or infusion. In the latter form, it is said by Professor Joerg, of Leipsic, who has experimented with it, to be less apt to irritate the alimentary canal than when administered in substance. The dose of the powder is from thirty to ninety grains, repeated three or four times a day.

* Recently valerianic acid has been obtained from various sources as a result of chemical reaction. A relation has been discovered between it and fusel oil (*Alcohol Amylicum*, Dub.), similar to that which exists between acetic acid and alcohol. *Amyle* ($C_{10}H_{11}$) is a compound radical, which by uniting with one eq. of oxygen and one of water forms fusel oil ($C_{10}H_{11}O+HO$). This, by the absorption of two eqs. of oxygen and the loss of two eqs. of hydrogen, is converted into hydrated valerianic acid ($C_{10}H_9O_3+HO$). Such a change may be effected by exposing the fusel oil to various oxidizing influences. (See *Alcohol Amylicum* and *Sodæ Valerianas* in the second part of this work.)—*Note to the ninth edition.*

The tincture is also officinal. As the virtues of valerian reside chiefly in the volatile oil, the medicine should not be given in decoction or extract. The distilled water is used on the continent of Europe; and the volatile oil is occasionally substituted with advantage for the root. The dose of the oil is four or five drops.

VERATRUM. *Sex. Syst.* Polygamia Monœcia.—*Nat. Ord.* Melanthaceæ.

Gen. Ch. HERMAPHRODITE. *Calyx* none. *Corolla* six-petaled. *Stamens* six. *Pistils* three. *Capsules* three, many-seeded. MALE. *Calyx* none. *Corolla* six-petaled. *Stamens* six. *Pistils* a rudiment. *Willd.*

Botanists who reject the class *Polygamia* of Linnæus, place this genus in the class and order *Hexandria Triygnia*, with the following character. "Polygamous. *Corolla* six-parted, spreading, segments sessile and without glands. *Stamens* inserted upon the receptacle. *Capsules* three, united, many-seeded." *Nuttall.*

Veratrum album. Willd. *Sp. Plant.* iv. 895; Woodv. *Med. Bot.* p. 754, t. 257. This is an herbaceous plant, with a perennial, fleshy, fusiform root or rhizoma, yellowish-white externally, pale yellowish-gray within, and beset with long cylindrical fibres of a grayish colour, which constitute the true root. The stem is three or four feet high, thick, round, erect, and furnished with alternate leaves, which are oval, acute, entire, plaited longitudinally, about ten inches long by five in breadth, of a yellowish-green colour, and embrace the stem at their base. The flowers are greenish, and arranged in a terminal panicle.

The white hellebore is a native of the mountainous regions of continental Europe, and abounds in the Alps and Pyrenees. All parts of the plant are said to be acrid and poisonous; but the root (rhizoma) only is officinal. This is brought to us from Germany in the dried state, in pieces from one to three inches long by an inch or less in mean diameter, cylindrical or in the shape of a truncated cone, internally whitish, externally blackish, wrinkled, and rough with the remains of the fibres which have been cut off near their origin. Sometimes the fibres continue attached to the root. They are numerous, yellowish, and of the size of a crow's quill. White hellebore deteriorates by keeping.

Properties. The fresh root has a disagreeable odour, which is lost by drying. The taste is at first sweetish, afterwards bitterish, acrid, burning, and durable. The powdered root is grayish. Analyzed by Pelletier and Caventou, white hellebore was found to contain an oily matter consisting of olein, stearin, and a volatile acid; *supergallate of veratria*, a yellow colouring matter, starch, gum, lignin, silica, and various salts of lime and potassa. The medicinal properties of the root reside in the veratria, which was first discovered in the seeds of *Veratrum Sabadilla*, and probably exists in other plants belonging to the same family. For an account of this alkaloid, see the article *Veratria*, among the preparations. Simon believed that he had found two new vegetable alkalies in white hellebore, one of which was named *barytina*, from being precipitated, like baryta, from its solution in acetic or phosphoric acid by sulphuric acid or the sulphates; the other *jervina*, from the Spanish name for a poison obtained from the root of white hellebore. (*Pharm. Cent. Blatt*, 1837, p. 191.)

Medical Properties and Uses. White hellebore is a violent emetic and cathartic, capable of producing dangerous and fatal effects when incautiously administered. Even in small doses it has sometimes occasioned severe vomiting, hypercatharsis with bloody stools, and alarming symptoms of general prostration. Like many other acrid substances, it appears, in small doses, to be a general stimulant to the secretions. Applied externally upon a portion of the surface denuded of the cuticle, as upon ulcers, for example, it gives rise to griping pain in the bowels, and sometimes violent purging. When snuffed up the nostrils, it occasions great irritation with violent sneezing, and its use in this way is not free from danger. It was employed by the ancients in dropsy, mania, epilepsy, leprosy, elephantiasis, and other obstinate disorders, not without occasional advantage; but the severity of its operation has led to its general abandonment as an internal remedy. It is sometimes used as an errhine, diluted with some mild powder, in cases of gutta serena and lethargic affections; and, in the shape of decoction, or of ointment prepared by mixing the pulverized root with lard, has been found beneficial as an external application in the itch, and other cutaneous eruptions. From the resemblance of its operation to that of the *eau medicinale d'Husson*, so celebrated for the cure of gout, it was at one time, though erroneously, conjectured to be the chief constituent of that remedy. A mixture of the wine of white hellebore and the wine of opium, in the proportion of three parts of the former to one of the latter, was introduced into use by Mr. Moore, of London, as a substitute for the *eau medicinale*, and was considerably employed in gouty and rheumatic affections.

In whatever way white hellebore is used, it requires cautious management. It has been given in doses varying from one grain to a scruple. Not more than two grains should be administered at first. When employed as an errhine, it should be mixed with five or six parts of pulverized liquorice root, or other inactive powder. Ten or twelve grains of the mixture may be snuffed up the nostrils at one time. Veratria acts in a similar manner with the white hellebore, but is much more powerful. From one-twelfth to one-sixth of a grain may be given in pill or alcoholic solution, and repeated three or four times in the twenty-four hours, till it nauseates or purges. For an account of its practical applications the reader is referred to *Veratria*, among the Preparations, in the second part of this work.

VERATRUM VIRIDE. *U. S.*

American Hellebore.

The rhizoma of Veratrum viride. *U. S.*

VERATRUM. See VERATRUM ALBUM.

Veratrum viride. Willd. *Sp. Plant.* iv. 896; Bigelow, *Am. Med. Bot.* ii. 121. The American hellebore, known also by the names of *Indian poke*, *poke root*, and *swamp hellebore*, has a perennial, thick, fleshy root or rhizoma, the upper portion of which is tunicated, the lower solid, and beset with numerous whitish fibres or radicles. The stem is annual, round, striated, pubescent, and solid, from three to six feet in height, furnished with green bright leaves, and terminating in a panicle of greenish-yellow flowers. The leaves gradually decrease in size as they ascend. The lower are from six inches to a foot long, oval, acuminate, plaited, nerved, and pubescent; and embrace the stem at their base, thus affording it a sheath for a considerable portion of its length. Those on the upper part of the stem, at the origin of the flowering branches, are oblong-lanceolate.

The panicle consists of numerous flowers, distributed in racemes with downy peduncles. Each flower is accompanied with a downy pointed bracte, much longer than its pedicel. There is no calyx, and the corolla is divided into six oval acute segments, thickened on the inside at their base, with the three alternate segments longer than the others. The six stamens have recurved filaments, and roundish two-lobed anthers. The germs are three, with recurved styles as long as the stamens. Some of the flowers have only the rudiments of pistils. Those on the upper end of the branchlets are barren, those on the lower portion fruitful. The fruit consists of three cohering capsules, separating at top, opening on the inner side, and containing flat imbricated seeds.

This indigenous species of Veratrum is found from Canada to the Carolinas, inhabiting swamps, wet meadows, and the banks of mountain streamlets. Early in the spring, before the stem rises, it bears a slight resemblance to the *Symplocarpus fœtidus*, with which it is very frequently associated; but the latter sends forth no stem. From May to July is the season for flowering. The root should be collected in autumn, and should not be kept longer than one year, as it deteriorates by time.

The root of the American hellebore has a bitter acrid taste, leaving a permanent impression in the mouth and fauces. In sensible properties it bears a close resemblance to white hellebore; and from this circumstance, as well as from the strong botanical affinity of the two plants, it is highly probable that it contains veratria. The experiments of Mr. Mitchell and Mr. Worthington, of Philadelphia, go to strengthen this probability. (See *Am. Journ. of Pharm.*, ix. 181, and x. 89.)

Medical Properties and Uses. American hellebore has been thought to resemble its European congener in its effects upon the system, though asserted by Dr. Osgood to be wholly destitute of cathartic properties. In addition to its emetic action, which is often violent and long-continued, it is said to increase most of the secretions, and, when freely taken, to exercise a powerful influence over the nervous system, indicated by faintness, somnolency, vertigo, headache, dimness of vision, and dilated pupils. According to Dr. Osgood, it reduces the frequency and force of the pulse, sometimes, when taken in full doses, as low as thirty-five strokes in the minute. It may be safely substituted for the European root in most cases in which the latter is employed; and is highly recommended as a substitute for colchicum by Dr. Tully, of New Haven. Gouty, rheumatic, and neuralgic affections are those to which it appeared best adapted. For an account of its medical properties and applications, the reader is referred to a paper by Dr. Charles Osgood, of Providence, in the *American Journal of the Medical Sciences*, vol. xvi. p. 296. It may be used in substance, tincture, or extract. Dr. Osgood states the dose in which it will generally prove emetic at from four to six grains of the powder, one or two fluidrachms of a tincture made in the proportion of six ounces of the fresh root to a pint of alcohol, and one or two grains of an extract made by inspissating the juice of the root. The medicine, however, should, in most cases, be given in doses insufficient to vomit.

Since the publication of the last edition of this work, various communications have appeared in our Southern medical journals, tending to prove that American hellebore is applicable to the treatment of numerous febrile and inflammatory affections, in which an indication is offered for reducing the frequency of the pulse. The credit of calling public attention to it is due more especially to Dr. W. C. Norwood, of Cokesbury, South Carolina, who has employed it with great success in pulmonary inflammation, typhoid fever, &c., and believes that it affords the means of reducing the frequency of the pulse at will. He employs a saturated tincture made by macerating eight ounces of the dried root in sixteen ounces of alcohol for at least two weeks. Of this he gives to an adult man eight

drops, and repeats the dose every three hours, increasing by one drop at each dose, until the pulse is reduced, or nausea and vomiting are occasioned, when it is to be diminished one-half, and continued so long as may be necessary to prevent a return of the symptoms. (*Charleston Med. Journ. and Rev.*, vii. 768.) Others have found the commencing dose of Dr. Norwood somewhat too large. From its powerful emetic properties, and the prostration resulting from excessive doses, it should always be used with great caution, and its effects carefully observed. Its nauseating and depressing effects are best counteracted by opiates and alcoholic stimulants. W.

Wine is the fermented juice of the grape, the fruit of Vitis vinifera of botanists, the description of which will be found under another head. (See *Uva Passa.*) The juice of sweet grapes consists of a considerable quantity of grape sugar, a peculiar matter of the nature of ferment or yeast, and a small portion of extractive, tannic acid, bitartrate of potassa, tartrate of lime, common salt, and sulphate of potassa; the whole dissolved or suspended in a large quantity of water. Sour grapes contain, in addition, a peculiar acid isomeric with the tartaric, called *paratartaric acid.* (See *page* 53.) Grape juice, therefore, embraces all the ingredients essential to the production of the vinous fermentation, and requires only the influence of the atmosphere and a proper temperature to convert it into wine. (See *page* 60.)

Preparation. When the grapes are ripe, they are gathered, and trodden under foot in wooden vessels with perforated bottoms, through which the juice, called the *must*, runs into a vat placed beneath. The temperature of the air being about 60°, the fermentation gradually takes place in the must, and becomes fully established after a longer or shorter period. In the mean time, the must becomes sensibly warmer, and emits a large quantity of carbonic acid, which causes the more solid parts to be thrown to the surface in a mass of froth having a hemispherical shape, called the *head.* The liquor from being sweet becomes vinous, and assumes a deep-red colour if the product of red grapes. After a while the fermentation slackens, when it becomes necessary to accelerate it by thoroughly mixing the contents of the vat. When the liquor has acquired a strong vinous taste, and become perfectly clear, the wine is considered formed, and is racked off into casks. But even at this stage of the process, the fermentation continues for several months longer. During the whole of this period, a frothy matter is formed, which for the first few days collects round the bung, but afterwards precipitates along with colouring matter and tartar, forming a deposit which constitutes the wine-lees.

Division and Nomenclature. Wines, according to their colour, are divided

into the red and white; and, according to their taste and other qualities, are either spirituous, sweet, dry, light, sparkling, still, rough, or acidulous. *Red wines* are derived from the must of black grapes, fermented with their husks; *white wines*, from white grapes, or from the juice of black grapes fermented apart from their skins. The other qualities of wines, above enumerated, depend on the relative proportions of the constituents of the must, and on the mode in which the fermentation is conducted. The essential ingredients of the must as a fermentable liquid are water, sugar, and a ferment. If the juice be very saccharine, and contain sufficient ferment to sustain the fermentation, the conversion of the sugar into alcohol will proceed until checked by the production of a certain amount of the latter, and there will be formed a *spirituous* or *generous* wine. If, while the juice is highly saccharine, the ferment be deficient in quantity, the production of alcohol will be less, and the redundancy of sugar proportionably greater, and a *sweet wine* will be formed. When the sugar and ferment are in considerable amount, and in the proper relative proportions for mutual decomposition, the wine will be strong bodied and sound, without any sweetness or acidity, and of the kind called *dry*. A small proportion of sugar can give rise only to a small proportion of alcohol, and consequently the less saccharine grapes will generate a comparatively weak, or *light wine*, which will be sound and stable in its constitution, in case the ferment is not in excess, but otherwise liable to pass into the acetous fermentation and become acescent. In case the wine is bottled before the fermentation is fully completed, the process will proceed slowly in the bottles, and the carbonic acid generated, not having vent, will impregnate the wine, and render it effervescing and *sparkling*. The *rough* or *astringent* wines owe their flavour to a portion of tannic acid derived from the husks of the grape; and the *acidulous* wines to the presence of carbonic acid or an unusual proportion of tartar. Several of the above qualities often co-exist. Thus a wine may be spirituous and sweet, spirituous and rough, sweet and rough, light and sparkling, &c.

Wines are made in many countries, and are known in commerce by various names, according to their source. Thus, *Portugal* produces port and lisbon; *Spain*, sherry, saint lucar, malaga, and tent; *France*, champagne, burgundy, hermitage, vin de grave, sauterne, and claret; *Germany*, hock and moselle; *Hungary*, tokay; *Sicily*, marsala or Sicily madeira, and lissa; the *Cape of Good Hope*, constantia; *Madeira and the Canaries*, madeira and teneriffe.

In the United States the first attempt to manufacture wine, on an extended scale, was made towards the close of the last century, at Spring Mill, near Philadelphia, by Mr. Peter Legaux, agent of the Pennsylvania Vine Company, and proved unsuccessful. The native grape found most suitable, after the foreign had failed on account of the climate, was the *Schuylkill muscadel grape*. The next attempt was made by the Swiss at Vevay, Indiana, with the Schuylkill grape, and was partially successful; a rough red wine being manufactured which met with a ready sale in the neighbouring States. In a few years the manufacture of this wine languished, being superseded by foreign wines. For a considerable period, investigations have been in progress to determine the adaptation of our various native grapes for making wine. The *Catawba grape*, introduced to public notice by Major Adlum, of Washington city, about the year 1825, is a superior wine grape, producing a wine resembling hock. Mr. N. Longworth, of Cincinnati, considers it, undoubtedly, a native grape. The *Herbemont* and *Missouri* are both good wine grapes, the latter producing a wine resembling madeira. The *Scuppernong grape*, indigenous to North Carolina, yields a hard dry wine like hock; and the vine is a very abundant bearer. According to Mr. R. Buchanan, this grape produces from two to three thousand gallons of wine per acre. (*Treatise on the Cultivation of the Grape.* Cincinnati, 1850.) The climate of

Texas is peculiarly favourable to the growth of the grape vine. The *El Paso grape* is found in the vicinity of the falls of the Rio Grande, and the *great mustang* grows luxuriantly in every part of the State, and yields a superior red wine. (See *Patent Office Report* for 1847.)

Properties. Wine, considered as the name of a class, may be characterized as a spirituous liquid, the result of the fermentation of grape-juice, and containing colouring matter, and some other substances, which are either combined or intimately blended with the spirit. All its other qualities vary with the nature of each particular wine. The principal wines used for medicinal purposes are the officinal wines, sherry and port, together with madeira, teneriffe, claret, and champagne.

Sherry (VINUM ALBUM) is of a deep-amber colour, and when good possesses a dry aromatic flavour and fragrancy, without any acidity. It ranks among the stronger white wines, and contains between 19 and 20 per cent. by measure of alcohol of sp. gr. 0·825. The United States and British Pharmacopœias agree in indicating it as the officinal white wine. It is prepared in the vicinity of Xeres in Spain, and hence its English name *sherry*. This wine is supposed to have been the *sack* of Shakspeare, so called from the word *sec* (dry), in allusion to its being a dry wine.

Port (VINUM RUBRUM) is of a deep-purple colour, and, in its new state, is a rough, strong, and slightly sweet wine. When kept a certain time in bottles, it deposits a considerable portion of its astringent matter, loses the greater part of its sweetness, acquires more flavour, and retains its strength. If too long kept, it deposits the whole of its astringent and colouring matter, and becomes deteriorated. Considerable quantities of brandy are usually added to it, which causes its heating quality on the palate. It is the strongest of the wines in common use. It was first made officinal in the U. S. Pharmacopœia of 1850.

Madeira is the strongest of the white wines in general use. It is a slightly acid wine, and, when of proper age and in good condition, has a rich, nutty, aromatic flavour. As it occurs in the market, however, it is of very variable quality, on account of the adulterations and mixtures to which it is subjected after importation. The madeira consumed in this country is generally better than that used in England; its adulteration being practised to a less extent with us, and our climate being more favourable to the improvement of the wine.

Teneriffe is a white wine, of a slightly acid taste, and, when of good quality, of a fine aromatic flavour. Its average strength is about the same as that of sherry. It is made from the same grape as madeira, to which it bears a close resemblance.

Claret, called in France *vin de Bordeaux*, from its being produced near that city, in the district of Medoc, is a red wine, and from its moderate strength is ranked as a light wine. It has a deep-purple colour, and, when good, a delicate taste, in which the vinous flavour is blended with slight acidity and astringency. The most esteemed kinds are the clarets called *Château-Margaux*, *Château-Lafite*, and *Château-Latour*. Another celebrated variety is the *Château-Haut Brion* of the Pays de Grave. Claret is the variety of French wine most extensively consumed in the United States.

Adulterations. Wines are very frequently adulterated, and counterfeit mixtures are often palmed upon the public as genuine wine. Free sulphuric acid in red wines cannot be detected by barytic salts; for all wines contain a small quantity of the soluble sulphates. It may be discovered, however, by dropping the suspected red wine on a piece of common glazed paper, containing starch. If the wine be pure, the spot, when dry, will be violet-blue, and the paper unaltered in texture; but if the wine contain even a thousandth part of sulphuric acid, the paper will be spotted rose-red, and prove brittle and friable when slightly rubbed

between the fingers. (*Lassaigne*, *O. Henri*, and *Bayard.*) Formerly the wine dealers were in the habit of putting litharge into wines that had become acescent. The oxide of lead formed with the acetic acid acetate of lead, which, being sweet, corrected the defect of the wine, but at the same time rendered it poisonous. At the present day, this criminal practice is wholly abandoned. The adulteration is readily detected by sulphuretted hydrogen, which causes a black and flocculent precipitate. Mr. Brande assures us that, among the numerous samples of wine of suspected purity which he had examined, he had not found one containing any poisonous ingredient fraudulently introduced. Lead, in minute quantity, according to this writer, may sometimes be detected in wines; but it is derived invariably from shot in the bottle, or from some analogous source. Rhenish wines, when acid from the presence of free tartaric or acetic acid, may be restored by the addition of neutral tartrate of potassa, which gives rise to the formation of cream of tartar. (*Andrew Ure.*) Spurious mixtures, frequently containing very little of the fermented juice of the grape, and which are sold as particular wines, may not be poisonous; but are, notwithstanding, highly pernicious in their effects upon the stomach, and always produce mischief and disappointment, when depended on as therapeutic agents. The wines most frequently imitated are port and madeira; and cider is the chief ingredient in the spurious mixtures. *English port* is sometimes made of a small portion of real port, mixed with cider, juice of elder berries, and brandy, and rendered astringent with logwood and alum.

Composition. Wines consist mainly of water and alcohol. They contain, also, grape sugar, gum, extractive, colouring matter, tannic, malic, and carbonic acids, bitartrate of potassa (tartar), tartrate of lime, volatile oil, and œnanthic ether. The volatile oil has never been isolated, but is supposed to be the cause of the delicate flavour and odour of wine, called the *bouquet.* According to Dr. F. L. Winckler, the bouquet depends upon the presence of a nitrogenous compound of a volatile organic acid with a volatile base, which has a different smell in different wines. *Œnanthic ether* (*œnanthate of ether, œnanthate of oxide of ethyle*) was discovered by Pelouze and Liebig. It is obtained towards the end of the distillation of wine on the great scale for making brandy. It forms only about one part in ten thousand of the wine. It is a mobile, oily, colourless liquid, having the peculiar unpleasant smell which is perceived in a bottle which has contained wine. Its sp. gr. is 0·862, and boiling point 435°. Its formula is $C_{18}H_{18}O_3 = C_{14}H_{13}O_2$ (œnanthic acid) $+ C_4H_5O$ (ether). Œnanthic ether must not be confounded with the substance upon which the bouquet of wine is supposed to depend. The other ingredients of wine, above enumerated, are not to be supposed present in every wine. Thus, sugar is present in sweet wines, tannic acid in rough wines, and carbonic acid in those that effervesce. The different kinds of wine derive their various qualities from the mode of fermentation, the nature of the grape, and the soil and climate in which it may have grown. The alcohol in pure wine is that which results from the vinous fermentation, and is intimately united with the other ingredients of the liquid; but with almost all the wines of commerce a portion of brandy is mixed, the state of union of which is probably different from that of the natural alcohol of the wine. By the British custom-house regulations ten per cent. of brandy may be added to wines after importation; but to good wines not more than four or five per cent. is added.

The intoxicating ingredient in all wines is the alcohol which they contain; and hence their relative strength depends upon the quantity of this substance entering into their composition. The alcohol, however, naturally in wine, is so blended with its other constituents, as to be in a modified state, which renders it less intoxicating and less injurious than the same quantity of alcohol, separated by distillation and diluted with water. Mr. Brande published in 1811 a very interesting table, giving the per centage by measure of alcohol of the sp. gr. 0·825

in different kinds of wine. Similar tables have since been published by M. Julia-Fontenelle, and by Dr. Christison. An abstract of their results is given in the following table, the proof spirit of Dr. Christison's table (0·920) being reduced, for the sake of comparison, to the standard of 0·825, the density of the spirit adopted by Mr. Brande. The results of Julia-Fontenelle are distinguished by the letter J.; those of Dr. Christison by the letter C. The rest are Mr. Brande's.

Table of the Proportion by Measure of Alcohol (sp. gr. 0·825) contained in 100 parts of different Wines.

Lissa (mean)	25·41	Vidonia	19·25
Raisin wine (mean)	25·12	Alba flora	17·26
Marsala [Sicily madeira] (mean)	25·09	Zante	17·05
Port, strongest	25·83	Malaga	17·26
mean	22·96	White hermitage	17·43
weakest	19·00	Rousillon (mean)	18·13
strongest (C.)	20·49	Claret, strongest	17·11
mean (C.)	18·68	mean	15·10
weakest (C.)	16·80	weakest	12·91
White port (C.)	17·22	ditto (J.)	14·73
Madeira, strongest	24·42	vin ordinaire (C.)	10·42
mean	22.27	Chateau-Latour, 1825, (C.)	9·38
weakest	19·24	first growth, 1811, (C.)	9·32
strongest (C.)	20·35	Malmsey madeira	16·40
Sercial madeira	21·40	Ditto (C.)	15·60
Ditto (C.)	18·50	Lunel	15·52
Sherry, strongest	19·81	Ditto (J.)	18·10
mean	19·17	Sheraaz	15·52
weakest	18·25	Ditto (C.)	15·56
strongest (C.)	19·31	Syracuse	15·28
mean (C.)	18·47	Sauterne	14·22
weakest (C.)	16·96	Burgundy (mean)	14·57
Amontillado (C.)	15·18	Hock (mean)	12·08
Teneriffe	19·79	Nice	14·63
Ditto (C.)	16·61	Barsac	13·86
Colares	19·75	Tent	13·30
Lachryma Christi	19·70	Champagne (mean)	12·61
White constantia	19·75	Ditto (J.)	12·20
Red constantia	18·92	Red hermitage	12·32
Lisbon	18·94	Vin de Grave (mean)	13·37
Ditto (C.)	19·09	Frontignac (Rives Altes)	12·79
Bucellas	18·49	Ditto (J.)	21·80
Red madeira (mean)	20·35	Ditto (C.)	12·29
Cape muschat	18·25	Côte rôtie	12·32
Cape madeira (mean)	20·51	Tokay	9·88
Grape wine	18·11	Rudesheimer, first qual., (C.)	10·14
Calcavella (mean)	18·65	inferior (C.)	8·35
		Hambacher, first quality, (C.)	8·88

The alcoholic strength of wines may be ascertained, with sufficient precision, by the *ebullioscope* of Conaty, or the *dilatometer* of Silbermann; the indications of the former instrument depending upon the determination of the boiling point of the wine; of the latter, upon its dilatation, when heated through a given interval of temperature. For a description of these ingenious instruments, the reader is referred to the *Journ. de Pharmacie*, for Feb. 1849.

Dr. Christison considers it a mistake to suppose that wines become stronger by being kept a long time in cask. His experiments appear to prove the reverse. While, however, the wine is not rendered more alcoholic by age, its flavour is improved, and its apparent strength increased.

Besides the grape, a number of other fruits yield a juice susceptible of the vinous fermentation. The infusion of malt, also, is capable of undergoing this process, and becomes converted into the different kinds of porter and ale. The product in all these cases, though not commonly called a wine, is nevertheless a vinous liquor, and may be classed among the wines properly so called. The following is a list of these vinous liquors, together with the per centage of alcohol which they contain, as ascertained by Mr. Brande:—Currant wine, 20·55; gooseberry wine, 11·84; orange wine, 11·26; elder wine, 8·79; cider, from 5·21 to 9·87; perry, 7·26; mead, 7·32; Burton ale, 8·88; Edinburgh ale, 6·20; brown stout, 6·80; London porter, 4·20; small beer, 1·28. According to L. Hoffmann Burton ale consists, in the 100 parts, of carbonic acid 0·04, absolute alcohol 6·62, extract of malt 14·97, and water 78·37; and pale ale, of carbonic acid 0·07, absolute alcohol 5·57, extract of malt 4·62, and water 89·74.

Medical Properties and Uses. Wine is consumed in most civilized countries; but in a state of health is at least useless, if not absolutely pernicious. The degree of mischief which it produces depends on the character of the wine. Thus the light wines of France are comparatively harmless; while the habitual use of the stronger wines, such as sherry, port, madeira, &c., even though taken in moderation, is always injurious, as having a tendency to induce gout and apoplexy, and other diseases dependent on plethora and over-stimulation. All wines, however, when used habitually in excess, are productive of bad consequences. They weaken the stomach, produce disease of the liver, and give rise to dropsy, gout, apoplexy, tremors, and not unfrequently mania. Nevertheless, wine is an important medicine, productive of the best effects in certain diseases. As an article of the materia medica, it ranks as a stimulant and antispasmodic. In the convalescence from protracted fever, it is frequently the best remedy that can be employed. In certain stages of typhoid fevers, and in extensive ulceration and gangrene, this remedy, either alone, or conjoined with bark and opium, is often our main dependence. In low febrile affections, if it increase the fulness and lessen the frequency of the pulse, mitigate delirium, and produce a tendency to sleep, its further use may be deemed proper; but, on the contrary, if it render the pulse quicker, augment the heat and thirst, produce restlessness, or increase delirium, it should be immediately laid aside as injurious. In some convulsive diseases, as for example tetanus, wine, liberally given, has often proved useful.

Wine, when used medicinally, should be good of its kind; for otherwise it will disagree with the stomach, and prove rather detrimental than useful. The individual wine selected for internal exhibition must be determined by the nature of the disease, and the particular object in view. *Sherry*, when in good condition, is a fine wine, and, being free from all acid, is to be preferred whenever the stomach is delicate, or has a tendency to dyspeptic acidity. Good *madeira* is the most generous of the white wines, particularly adapted to the purpose of resuscitating debilitated constitutions, and of sustaining the sinking energies of the system in old age. The slight acidity, however, of pure madeira causes it to disagree with some stomachs, and renders it an improper wine for gouty persons. *Teneriffe* is a good variety of white wine for medicinal use, being of about a medium strength, and agreeing very well with most stomachs. *Port* is generally used in cases of pure debility, especially when attended with a loose state of the bowels, unaccompanied by inflammation. In such cases it often acts as a powerful tonic as well as stimulant, giving increased activity to all the functions, especially digestion. *Claret* is much less heating, and is often

useful on account of its aperient and diuretic qualities. Champagne is applicable to the sinking stage of low fevers, and is often useful in the debility of the aged.

All the acidulous wines are contra-indicated in the gouty and uric acid diathesis; as they are apt to convert the existing predisposition into disease.

The quantity of wine which may be given with advantage in disease is very variable. In low fevers, it may be administered to the extent of a bottle or more in twenty-four hours, either pure, or in the form of *wine-whey*. This is made by adding to a pint of boiling milk from a gill to half a pint of white wine, straining without pressure to separate the curd, and sweetening the clear whey with loaf sugar. Wine-whey forms a safe and grateful stimulus in typhoid fevers, and in other febrile affections, which, after depletion, may tend to a state of deficient action, and be accompanied with a dry skin. Under these circumstances, it often acts as a diaphoretic, and, when used of moderate strength, without stimulating the system injuriously.

Pharmaceutical Uses. White wine is employed as a menstruum to extract the virtues of several plants, and the preparations thus formed are called *vinous tinctures* or *medicated wines*. Tartar emetic and iron are the only mineral substances prepared in a similar manner. (See *Vinum Antimonii* and *Vinum Ferri*.) For the peculiar powers of wine as a menstruum, see *Vina Medicata*. B.

VIOLA. *U. S. Secondary, Lond., Ed.*

Violet.

The herb of Viola pedata. *U.S.* Viola odorata. The recent petal. *Lond.* The flowers. *Ed.*

Violette odorante, *Fr.;* Wohlriechendes Veilchen, *Germ.;* Violetta, *Ital.;* Violeta, *Span.*

Viola. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Violaceæ.

Gen. Ch. Calyx five-leaved. *Corolla* five-petalled, irregular, horned at the back. *Anthers* cohering. *Capsule* superior, three-valved, one-celled.

This genus includes numerous species, of which, though perhaps all or nearly all are possessed of analogous properties, two only are recognised as officinal, *Viola odorata*, by the London and Edinburgh Colleges, and *Viola pedata*, by our National Pharmacopœia. *Viola ovata*, an indigenous species, has been recommended as a remedy for the bite of the rattle-snake. (See a paper by Dr. Williams in the *Am. Journ. of the Med. Scien.*, xiii. 310.)

Viola odorata. Willd. *Sp. Plant.* i. 1163; Woodv. *Med. Bot.* p. 251, t. 89. This is a small, pretty, creeping plant, the runners of which are furnished with fibrous roots, and send up annually tufts of leaves and flowers. The leaves are heart-shaped, crenate, and supported on long petioles. The flowers are at the summit of delicate, quadrangular, channeled, radical peduncles. The leaves of the calyx are shorter than the petals, which are obovate, obtuse, unequal, and of a bluish-purple or deep-violet colour, except at the claws, which are whitish. The two lateral petals are spreading and bearded towards the base, the inferior furnished with a large spur, and the two upper reflected. In the centre are the stamens with very short filaments, and anthers slightly cohering by an orange-coloured membranous expansion.

The sweet violet is a native of Europe, growing in woods, hedges, and other shady places. It is cultivated in gardens both for its beauty and for medical use; and has been introduced into this country. It is valued chiefly for its flowers, which appear in April and May.

The flowers of this species of violet, besides their beautiful colour, have a peculiar agreeable odour, and a very slightly bitter taste. These properties they yield to boiling water; and their infusion affords a very delicate test for acids

and alkalies, being reddened by the former, and rendered green by the latter. Their odour is destroyed by desiccation; and the degree to which they retain their fine colour depends upon the care used in collecting and drying them. They should be gathered before being fully blown, deprived of their calyx, and rapidly dried, either in a heated room, or by exposing them to a current of very dry air. The flowers of other species are often mingled with them, and, if of the same colour, are equally useful as a chemical test.

In the root, leaves, flowers, and seeds of *Viola odorata*, M. Boulay discovered a peculiar alkaline principle, bearing some resemblance to *emetia*, but possessing distinct properties. He called it *violine;* but *violia* is its proper title, in accordance with the nomenclature adopted in this work. It is white, soluble in alcohol, scarcely soluble in water, and forms salts with the acids. It exists in the plant combined with malic acid, and may be obtained by treating with distilled water the alcoholic extract of the dried root, decomposing by means of magnesia the malate of violia contained in the solution, and extracting the alkali from the precipitated matters by alcohol, which yields it on evaporation. To obtain it entirely pure, a more complicated process is necessary. Orfila has ascertained that it is exceedingly active and even poisonous. It is probably contained in most of the other species of Viola.

Viola pedata. Willd. *Sp. Plant.* i. 1160; Curtis, *Bot. Mag.* 89. This is an indigenous species, without stems, glabrous, with many parted often pedate leaves, the segments of which are linear-lanceolate, obtuse, and nearly entire. The flowers are large and of a beautiful blue colour, often more or less variegated. The divisions of the calyx are linear and acute. The stigma is large, compressed at the sides, obliquely truncate and perforate at the apex. The plant grows in dry sandy hills and fields, and rocky woods, from New England to Carolina, and flowers in May and June.

Medical Properties, &c. of the Violets. The herbaceous parts of different species of violet are mucilaginous, emollient, and slightly laxative; and have been used in pectoral, nephritic, and cutaneous affections. Much was formerly thought of the *Viola tricolor*, or *pansy*, as a remedy in crusta lactea. A decoction in milk of a handful of the fresh herb was taken morning and evening, and a poultice made with the same decoction was applied to the affected part. Cures in numerous instances are said to have been effected by this treatment persevered in for some time. Our own *Viola pedata* is considered a useful expectorant and demulcent in pectoral complaints. (*Bigelow.*)

In Europe, a syrup prepared from the fresh flowers of *Viola odorata* is much employed as an addition to demulcent drinks, and as a laxative for infants. (See *Syrupus Violæ.*) The seeds were formerly considered useful in gravel, but are not now employed. The root, which has a bitter, nauseous, slightly acrid taste, acts in the dose of from thirty grains to a drachm as an emetic and cathartic. It is probable that the same property is possessed by the roots of all the violets, as it is known to be by several species of Ionidium, which belong to the same natural family. The existence in small proportion of the emetic principle, upon which the powers of the root probably depend, in the leaves and flowers, accounts for the expectorant properties long attributed to these parts of the plant.

Off. Prep. Syrupus Violæ. W.

WINTERA. *U. S. Secondary.*

Winter's Bark.

The bark of Drimys Winteri. *U. S.*

Ecorce de Winter, *Fr.;* Wintersche Rinde, *Germ.;* Corteccia Vinterana, *Ital.;* Corteza Winterana, *Span.*

Drimys. *Sex. Syst.* Polyandria Tetragynia.—*Nat. Ord.* Magnoliaceæ, *Juss.*; Winteraceæ, *Lindley.*

Gen. Ch. Calyx with two or three deep divisions. *Corolla* with two or three petals, sometimes more numerous. *Stamens* with the filaments thickened at the summit, and anthers having two separate cells. *Ovaries* from four to eight, changing into the same number of small, many-seeded berries. *A. Richard.*

Drimys Winteri. De Cand. *Prod.* i. 78; Carson, *Illust. of Med. Bot.* i. 11, pl. 5.—*Wintera aromatica.* Willd. *Sp. Plant.* ii. 1239; Woodv. *Med. Bot.* p. 647, t. 226. This is an evergreen tree, varying very much in size, sometimes rising forty or fifty feet in height, sometimes not more than six or eight feet. The bark of the trunk is gray, that of the branches green and smooth. Its leaves are alternate, petiolate, oblong, obtuse, somewhat coriaceous, entirely smooth, green on their upper surface, of a pale-bluish colour beneath, with two caducous stipules at their base. The flowers are small, sometimes solitary, but more frequently in clusters of three or four, upon the summit of a common peduncle about an inch in length, simple, or divided into as many pedicels as there are flowers. The tree is a native of the southern parts of South America, growing along the Straits of Magellan, and extending as far north as Chili. According to Martius it is found also in Brazil. The bark of the tree was brought to England, in the latter part of the sixteenth century, by Captain Winter, who attended Drake in his voyage round the world, and while in the Straits had learned its aromatic and medicinal properties. Since that period it has been occasionally employed in medicine.

It is in quilled pieces, usually a foot in length, and an inch or more in diameter, appearing as if scraped or rubbed on the outside, where the colour is pale-yellowish or reddish-gray, with red elliptical spots. On the inside the colour is that of cinnamon, though sometimes blackish. The pieces are sometimes flat and very large. The bark is two or three lines in thickness, hard and compact, and when broken exhibits on the exterior part of the fracture a grayish colour, which insensibly passes into reddish or yellowish towards the interior. The powder resembles in colour that of Peruvian bark. The odour is aromatic, the taste spicy, pungent, and even burning.

Winter's bark was found by M. Henry to contain resin, volatile oil, colouring matter, tannic acid, several salts of potassa, malate of lime, and oxidized iron. The presence of tannic acid and oxide of iron serves to distinguish it from *canella alba*, with which it has often been confounded.

Medical Properties and Uses. It is a stimulant aromatic tonic, and was employed by Winter as a remedy for scurvy. It may be used for similar purposes with cinnamon or canella alba, but is scarcely known in the medical practice of this country. The dose of the powder is about half a drachm. Another species, the *Drimys Chilensis* of De Candolle, growing in Chili, yields a bark having similar properties. (Carson, *Am. Journ. of Pharm.*, xix. 81.) W.

XANTHORRHIZA. *U. S. Secondary.*

Yellow-root.

The root of Xanthorrhiza apiifolia. *U. S.*

Xanthorrhiza. *Sex. Syst.* Pentandria Polygynia.—*Nat. Ord.* Ranunculaceæ.

Gen. Ch. Calyx none. *Petals* five. *Nectaries* five, pedicelled. *Capsules* five to eight, one-seeded, semibivalve. *Nuttall.*

Xanthorrhiza apiifolia. Willd. *Sp. Plant.* i. 1568; Barton, *Med. Bot.* ii. 203.—*X. tinctoria.* Woodhouse, *N. Y. Med. Repos.* vol. v. This is an indige-

nous shrub, two or three feet in height, with a horizontal root, which sends off numerous suckers. The stem is simple, rather thicker than a goose-quill, with a smooth bark, and bright-yellow wood. The leaves, which stand thickly at the upper part of the stem, are compound, consisting of several ovate-lanceolate, acute, doubly serrate leaflets, sessile upon a long petiole, which embraces the stem at its base. The flowers are small, purple, and disposed in long, drooping, divided racemes, placed immediately below the first leaves. The nectaries are obovate and bilobed, the styles usually about six or eight in number.

The yellow-root grows in the interior of the Southern, and in the Western States. Nuttall says that it is abundant on the banks of the Ohio. It flowers in April. The root is the part directed by the Pharmacopœia; but the bark of the stem possesses the same virtues.

The root is from three inches to a foot in length, about half an inch in thickness, of a yellow colour, and of a simple but extremely bitter taste. It imparts its colour and taste to water. The infusion is not affected by a solution of sulphate of iron. By the late Professor Barton the bark of the root was considered more bitter than its ligneous portion.

Medical Properties and Uses. Xanthorrhiza possesses properties closely analogous to those of columbo, quassia, and the other simple tonic bitters; and may be used for the same purposes, and in the same manner. Dr. Woodhouse employed it in the dose of two scruples, and found it to lie easily upon the stomach. W.

XANTHOXYLUM. *U. S. Secondary.*

Prickly Ash.

The bark of Xanthoxylum fraxineum. *U. S.*

Xanthoxylum. *Sex. Syst.* Dicœcia Pentandria.—*Nat. Ord.* Terebintaceæ, *Juss.;* Xanthoxylaceæ, *Lindley.*

Gen. Ch. Male. *Calyx* five-parted. *Corolla* none. Female. *Calyx* five-parted. *Corolla* none. *Pistils* five. *Capsules* five, one-seeded. *Willd.*

Xanthoxylum fraxineum. Willd. *Sp. Plant.* iv. 757; Bigelow, *Am. Med. Bot.* iii. 156. *X. Americanum.* Miller; Torrey and Gray, *Fl. of N. Am.* i. 214. The prickly ash is a shrub from five to ten feet in height, with alternate branches, which are covered with strong, sharp, scattered prickles. The leaves are alternate and pinnate, consisting of four or five pairs of leaflets, and an odd terminal one, with a common footstalk, which is sometimes prickly on the back, and sometimes unarmed. The leaflets are nearly sessile, ovate, acute, slightly serrate, and somewhat downy on their under surface. The flowers, which are small and greenish, are disposed in sessile umbels near the origin of the young shoots. The plant is polygamous, some shrubs bearing both male and perfect flowers, others only female. The number of stamens is five, of the pistils three or four in the perfect flowers, about five in the pistillate. Each fruitful flower is followed by as many capsules as it had germs. These capsules are stipitate, oval, punctate, of a greenish-red colour, with two valves, and one oval blackish seed.

This species of Xanthoxylum is indigenous, growing in woods and in moist shady places throughout the Northern, Middle, and Western States. The flowers appear in April and May, before the foliage. The leaves and capsules have an aromatic odour recalling that of the oil of lemons. The bark is the officinal portion.

This, as found in the shops, is in quilled pieces, from one or two lines to

nearly an inch in diameter, rather thin, externally of a darkish-gray colour diversified by whitish patches, with the epidermis in many pieces marked by closely set transverse cracks, internally finely striated longitudinally and somewhat shining, and, when derived from the smaller branches, exhibiting occasionally remains of the prickles. The bark is very light, brittle, nearly or quite inodorous, and of a taste which is at first sweetish and slightly aromatic, then bitterish, and ultimately acrid. The acrimony is imparted to boiling water and alcohol, which extract the virtues of the bark. Its constituents, according to Dr. Staples, besides fibrous substance, are volatile oil, a greenish fixed oil, resin, gum, colouring matter, and a peculiar crystallizable principle which he calls *xanthoxylin*, but of which the properties are not designated. (*Journ. of the Phil. Col. of Pharm.*, i. 165.) It is probably identical with the bitter crystalline principle found by MM. Chevallier and Pelletan in the bark of Xanthoxylum Clava Herculis, and named by them *xanthopicrite*.

A specimen of bark has been shown to us, collected on the shores of the Chesapeake Bay, and said to be the product of *Xanthoxylum Clava Herculis*, though probably derived from the trunk of the plant under consideration, as the X. Clava Herculis is a native of the West Indies, and not of the United States, and the *X. fraxineum* was considered by Linnæus as a variety of that species. The specimen referred to resembles the bark above described considerably in its general characters, but differs in consisting of irregular fragments of a bark of larger dimensions, flat, or but slightly rolled, and exhibiting on the outer surface of some of the fragments, large conical, corky eminences, which serve as the bases of the spines, and no doubt give to the trunk of the tree the rough, knotty appearance, which obtained for its congener the name of the Club of Hercules.

Dr. Bigelow states that the *Aralia spinosa*, or angelica tree, which grows in the Southern States, is occasionally confounded with *X. fraxineum*, in consequence partly of being sometimes called, like the latter, *prickly ash*. Its bark, however, in appearance and flavour, is entirely different from the xanthoxylum.

Medical Properties and Uses. Xanthoxylum is stimulant, producing, when swallowed, a sense of heat in the stomach, with more or less general arterial excitement, and a tendency to diaphoresis. It is thought to resemble mezereon and guaiac in its remedial action, and is given in the same complaints. As a remedy in chronic rheumatism, it enjoys considerable reputation in this country. The dose of the powder is from ten grains to half a drachm, to be repeated three or four times a day. A decoction, prepared by boiling an ounce in three pints of water down to a quart, may be given in the quantity of a pint, in divided doses, during the twenty-four hours. The powder has sometimes been employed as a topical irritant; and the bark, used as a masticatory, is a popular remedy for toothache, and has been recommended in palsy of the tongue. W.

ZINCUM. *U. S., Lond., Ed., Dub.*

Zinc.

Speltre; Zinc, *Fr.;* Zink, *Germ.;* Zinco, *Ital., Span.*

Zinc occurs native in two principal states; as a sulphuret, called *blende*, and as a carbonate or silicate, denominated *calamine*. It is found in various parts of the world, but most abundantly in Germany, from which country the United States are principally supplied. The metal is extracted generally from calamine. This is roasted and mixed with charcoal powder, and the mixture heated in iron cylinders placed horizontally over a furnace. When the reduction of the zinc

commences, iron receivers are adapted to the opening of the cylinder to receive the volatilized metal as it condenses. The metal is then melted and run into moulds, and forms *speltre*, or the zinc of commerce. In this state it contains iron, and traces of lead, cadmium, arsenic, copper, sulphur, and charcoal. To purify it from these substances, it must be subjected to a second distillation in a crucible, furnished with a tube passing through its bottom, and open at both ends; its upper extremity reaching a little more than half way up the interior of the crucible, and its lower end terminating above a vessel of water. The impure zinc being placed in the crucible, the cover luted on, and the fire applied, the pure zinc is volatilized, and, passing down the tube by a descending distillation, condenses in the water below.

Properties. Zinc has a bluish-white colour, a peculiar taste, and a perceptible smell when rubbed. Its texture is laminated, and its fracture crystalline. Its malleability and ductility are not very great. When perfectly pure, it may be reduced to thin leaves at ordinary temperatures; but the zinc of commerce requires to be heated to a temperature between 212° and 300° to render it sufficiently laminable to be rolled into sheets. The softness of zinc is peculiar, as is shown by the circumstance that it clogs the file when the attempt is made to reduce it to filings; and hence, if it be desired to have it in the divided form, it is necessary to submit it to fusion, and to triturate it at the moment of solidification. Its sp. gr. is about 6·8, its equivalent number 32·3, and symbol Zn. By experiments instituted to determine the point, Favre makes its equivalent 32·99, and Erdmann, 32·527. Subjected to heat, it fuses at 773°. At full redness it boils, and in close vessels may be distilled over; but in open ones it takes fire, and burns with a dazzling white flame, giving off dense white fumes. It dissolves in most of the acids with disengagement of hydrogen, and precipitates all the metals either in the metallic state, or in that of oxide. It forms but one well-characterized oxide (a protoxide), and but one sulphuret. A peroxide of uncertain composition was obtained by Thenard. The protoxide is officinal, and will be described under another head. (See *Zinci Oxidum.*)

Zinc of good quality dissolves in dilute sulphuric acid, with the exception of a scanty grayish-black residuum. If absolutely pure, it would be wholly dissolved. The solution is colourless, and yields white precipitates with ferrocyanuret of potassium and hydrosulphate of ammonia. Ammonia throws down from this solution a white precipitate, which is wholly dissolved when the alkali is added in excess. If copper be present, the solution will be rendered blue by the ammonia; and if iron be an impurity it will be thrown down by this alkali, but not redissolved by its excess. Arsenic may be detected, unless present in very minute proportion, by dissolving the zinc in pure dilute sulphuric acid in a self-regulating reservoir for hydrogen; when arsenuretted hydrogen will be formed, recognisable by its flame producing a dark stain on a white plate.

Zinc is extensively employed in the arts. It is the best metal that can be used, in conjunction with copper, for galvanic combinations. Combined with tin and mercury, it forms the amalgam for electrical machines. Its solution in dilute sulphuric acid furnishes the readiest method for obtaining hydrogen. With copper it forms *brass*, and, in the form of *sheet zinc*, it is employed to cover the roofs of houses, and for other purposes. It should never be used for culinary vessels, as it is soluble in the weakest acids.

The compounds of zinc are poisonous, but not to the same extent as those of lead. The oxide of zinc, at present used in painting as a substitute for white lead, is capable of producing a colic, resembling that caused by lead, and called *zinc colic*. It attacks workmen, exposed to the dust of the oxide while engaged in packing it in barrels, and yields to the remedies appropriate to the treatment of lead colic. (See *Chem. Gaz.*, Sept. 16, 1850.)

Pharmaceutical Uses. Zinc is never used as a medicine in the metallic state; but is employed in this state to form the officinal preparations, acetate, sulphate, and chloride of zinc. In combination it forms a number of important medicinal preparations, a list of which, with the synonymes, is subjoined.

Zinc is employed medicinally,

I. Oxidized.
- Zinci Oxidum, *U. S., Lond., Ed.;* Zinci Oxydum, *Dub.*

Ginger.

The rhizoma of Zingiber officinale. *U. S., Lond., Ed., Dub.*

Gingembre, *Fr.;* Ingwer, *Germ.;* Zenzero, *Ital.;* Gengibre, *Span.*

Zingiber. *Sex. Syst.* Monandria Monogynia.—*Nat. Ord.* Scitamineæ, *R. Brown;* Zingiberaceæ, *Lindley.*

Gen. Ch. Flowers spathaceous. Inner limb of the *corolla* with one lip. *Anther* double, with a simple recurved horn at the end. *Germen* inferior. *Style* enclosed in the furrow formed by the anther. *Loudon's Encyc. of Plants.*

Zingiber officinale. Roscoe, *Trans. Linn. Soc.* viii. 348; Carson, *Illust. of Med. Bot.* ii. 55, pl. 98.—*Amomum Zingiber.* Willd. *Sp. Plant.* i. 6; Woodv. *Med. Bot.* p. 731, t. 250. The ginger plant has a biennial or perennial, creeping, tuberous root or rhizoma, and an annual stem, which rises two or three feet in height, is solid, round, erect, and enclosed in an imbricated membranous sheathing. The leaves are lanceolate, acute, smooth, five or six inches long by about an inch in breadth, and stand alternately on the sheaths of the stem. The flower-stalk rises by the side of the stem from six inches to a foot high, and like it is clothed with oval, acuminate sheaths; but it is without leaves, and terminates in an oval, obtuse, bracteal, imbricated spike. The flowers are of a dingy yellow colour, and appear two or three at a time between the bracteal scales.

The plant is a native of Hindostan, and is cultivated in all parts of India. It is also cultivated in the West Indies, whither it was transplanted from the East, and at Sierra Leone in Africa. The flowers have an aromatic smell, and the stems, when bruised, are slightly fragrant; but the root is the portion in which the virtues of the plant reside. This is fit to be dug up when a year old. In the West Indies, the ginger crop is gathered in January and February, after the stems have withered. After having been properly cleansed, the root is scalded

in boiling water, in order to prevent germination, and is then rapidly dried. Thus prepared, it constitutes the ordinary ginger of commerce, or *black ginger* as it is sometimes called from the darkish colour which it acquires in the process. It is imported into this country chiefly from Calcutta, and is known to the druggists by the name of East India ginger; but recently considerable quantities have been brought from Africa, and some probably reaches us from the West Indies. In Jamaica another variety is prepared by selecting the best roots, depriving them of their epidermis, and drying them separately and carefully in the sun. This is called in the books *white ginger*, and is most highly valued. It reaches us from England, where it is said to undergo some further preparation, by which its appearance is improved. It is usually called in our markets *Jamaica ginger*. The root is also at present imported from the East Indies deprived of the epidermis. Considerable quantities are brought immediately from the West Indies in a recent state, and sold by the confectioners. A preserve is made from ginger by selecting the roots while young and tender, depriving them of their cortical covering, and boiling them in syrup. This is occasionally imported from the East and West Indies. When good it is translucent and tender.

The *recent root* is from one to four inches long, somewhat flattened on its upper and under surface, knotty, obtusely and irregularly branched or lobed, externally of a light-ash colour with circular rugæ, internally fleshy and yellowish-white. It sometimes germinates when kept in the shops.

The *common* or *black ginger* is of the same general shape, but has a dark ash-coloured wrinkled epidermis, which, being removed in some places, exhibits patches of an almost black colour, apparently the result of exposure. Beneath the epidermis is a brownish, resinous, almost horny cortical portion. The interior parenchyma is whitish and somewhat farinaceous. The powder is of a light yellowish-brown colour. This variety is most extensively used throughout the country.

The *Jamaica* or *white ginger* differs in being entirely deprived of epidermis, and white, or yellowish-white on the outside. The pieces are rounder and thinner, in consequence of the loss of substance in their preparation. They afford when pulverized a beautiful yellowish-white powder, which is brought from Liverpool in jars. This variety is firm and resinous, and has more of the sensible qualities of ginger than the black. The uncoated ginger of the East Indies resembles the Jamaica, but is darker. There is reason to believe that a portion at least of the white ginger of commerce has been subjected to a bleaching process, by which not only the exterior, but also the internal parts are rendered whiter than in the unprepared root. Trommsdorff found in a specimen which he examined, evidences of the presence of chlorides, sulphates, and lime; and concluded that the bleaching was effected by chlorine, or by chloride of lime and sulphuric acid. Having macerated some black ginger in water, deprived it of the cortical portion, treated it for twenty-four hours with sulphuric acid diluted with nine times its weight of water, and finally placed it in a mixture of chloride of lime and water, in which it was allowed to remain for two days, he found it, upon being washed and dried, to present an appearance closely resembling that of the finest white ginger, both on the surface and internally. (*Annal. der Pharm.*, xvii. 98.) According to Brande, ginger is often washed in whiting and water; and Pereira states that it is sometimes bleached by exposure to the fumes of burning sulphur.

General Properties. The odour of ginger is aromatic and penetrating, the taste spicy, pungent, hot, and biting. These properties gradually diminish, and are ultimately lost by exposure. The virtues of ginger are extracted by water and alcohol. Its constituents, according to M. Morin, are a volatile oil; a resin-

ous matter, soft, acrid, aromatic, and soluble in ether and alcohol; a sub-resin insoluble in ether; a little osmazome; gum; starch; a vegeto-animal matter; sulphur; acetic acid; acetate of potassa; and lignin. The peculiar flavour of the root appears to depend on the volatile oil, its pungency partly on the resinous or resino-extractive principle. A considerable quantity of very pure white starch may be obtained from it. The volatile oil, examined by A. Papousek, was yellow, of the odour of ginger, and of a hot aromatic taste. Its sp. gr. was 0·893, and boiling point 475° F. Deprived of water by distillation with anhydrous phosphoric acid, it consisted of carbon and hydrogen, with the formula $C_{10}H_8$, and therefore belongs to the camphene series. (See *Chem. Gaz.*, Jan. 1, 1853, p. 12.)

Those pieces of ginger which are very fibrous, light and friable, or worm-eaten, should be rejected.

Medical Properties and Uses. Ginger is a grateful stimulant and carminative, and is often given in dyspepsia, flatulent colic, and the feeble state of the alimentary canal attendant upon atonic gout. It is an excellent addition to bitter infusions and tonic powders, imparting to them an agreeable, warming, and cordial operation upon the stomach. When chewed it produces much irritation of the mouth, and a copious flow of saliva; and when snuffed up the nostrils, in a state of powder, excites violent sneezing. It is sometimes used as a local remedy in relaxation of the uvula, and paralysis of the tongue and fauces. Externally applied it acts as a rubefacient. It may be given in powder or infusion. The dose of the former is from ten grains to a scruple or more. The infusion may be prepared by adding half an ounce of the powder or bruised root to a pint of boiling water, and may be given in the dose of one or two fluidounces.

PART II.

PREPARATIONS.

The preparation of medicines, which constitutes the art of Pharmacy, comes within the peculiar province of the apothecary. It is for his guidance that the various formulæ of the Pharmacopœia have been arranged, and to him that their directions are especially addressed.*

A few general observations, therefore, of an explanatory nature, calculated to facilitate the progress of the pharmaceutical student, will not be misplaced under the present head. The duty of the apothecary is to obtain a supply of good medicines, to preserve them with care, to prepare them properly for use, and to dispense them. Our remarks will embrace each of these points.

The substances obtained from the mineral and animal kingdoms, and those furnished by the chemical manufacturer, are of a nature to admit of no general precepts as to their proper condition, which would not be suggested by the common sense of the purchaser. He must receive them as offered, and judge of their fitness for his purposes by his knowledge of the peculiar properties of each. The same remark applies to vegetable substances from abroad; but with respect to indigenous plants, the apothecary is frequently called upon to exercise his judgment in relation to their collection and desiccation, and will derive advantage from some brief practical rules upon the subject.

Collecting and Drying of Plants. The proper mode of proceeding varies according to the nature of the part used. The different parts of plants are to be gathered at the period when the peculiar juices of the plant are most abundant in them. In the *roots* of *annual* plants this happens just before the time of flowering; in the roots of *biennials*, after the vegetation of the first year has ceased; and in those of *perennials*, in the spring before vegetation has commenced. They should be washed, and the small fibres, unless they are the part employed, should be separated from the fleshy solid part, which is to be cut in slices previously to being dried. *Bulbs* are to be gathered after the new bulb is perfected, and before it has begun to vegetate, which is at the time the leaves decay. *Barks* whether of the root, trunk, or branches, should be gathered in the autumn or early in the spring. The dead epidermis, and the decayed parts are to be separated. Of some trees, as the slippery elm, it is the inner bark only that is preserved. *Leaves* are to be gathered after their full development, before

* These preliminary observations to the second part of the work were originally prepared by Mr. Daniel B. Smith, President of the Philadelphia College of Pharmacy. They have from time to time been somewhat modified since their first appearance; but never to the same extent as in the present edition. The alterations now made are such as the improvements in Pharmacy have suggested, and were deemed necessary to render the work a proper exponent of the present state of knowledge upon the subject. The authors are happy to acknowledge their obligations, in the revision of this introduction, to Professor William Procter, of the Philadelphia College of Pharmacy.—*Note to the ninth edition.*

the fading of the flower. The leaves of biennial plants do not attain their perfect qualities until the second year. *Flowers* should in general be gathered at the time of their expansion, before or immediately after they have fully opened; and some, as the Rosa Gallica, while in the bud. *Aromatic herbs* are to be gathered when in flower. Leaves, flowers, and herbs are to be gathered in clear dry weather, in the morning, after the dew is exhaled. *Stalks and twigs* are collected in autumn; *seeds* at the period of their full maturity.

Vegetables should be dried as rapidly as is consistent with their perfect preservation. Those collected in the warm months and during dry weather, may, except in a few instances, be dried by spontaneous evaporation in a well-ventilated apartment; and some, as roots and barks, may be exposed to the direct rays of the sun. In spring and autumn, and especially in damp foggy, or rainy weather, the drying room should be artificially heated, and furnished with apertures near the top for the escape of the moist warm air, and others beneath in the direction of the prevailing wind so as to command a current of air. The arrangements for supplying heat, which may consist of a small stove, or a drum connected with a stove in another apartment, should be capable of regulation, so that the temperature may range between 70° and 100° Fahr. at will. The substances to be dried should be supported on wicker or tinned wire hurdles, arranged horizontally above each other, so that the ascending and lateral currents of air may pass over and through every part. *Fibrous roots* may be dried in the sun, or at a heat of from 65° to 80° in the drying room. *Fleshy roots* should be cut in transverse slices not exceeding half an inch in length, and, during the drying process, should be stirred several times to prevent moulding; the heat being at first maintained at about 100°. *Bulbs* must have the outer membranes peeled off: in other respects they are to be treated like fleshy roots. *Barks*, *woods*, and *twigs* readily dry in thin layers in the open air. *Leaves*, after separation from the stalks, should be loosely strewed over the hurdles, and their position changed twice a day till they become dry. When very succulent they require more care, in order to prevent discoloration. For dry and thin leaves the heat need not exceed 70°; for the succulent, it may be gradually raised to 100°. *Annual plants*, and *tops*, if not too juicy, may be tied loosely in small bundles, and strung on lines stretched across the drying room. *Flowers* must be dried carefully and rapidly so as to preserve their colour. They should be spread loosely on the hurdles and turned several times by stirring. When flowers or leaves owe their virtues to volatile oils, greater care is necessary. *Succulent fruits*, as berries, may be dried when in bunches by suspending them in the drying room.

The following table, taken from the Edinburgh Dispensatory, presents the amounts yielded by 1000 parts of the vegetables respectively mentioned, after being dried.

Roots of Angelica Archangelica	263	Leaves of Digitalis purpurea	180
Aspidium Filix Mas	500	Hyoscyamus niger	135
Inula Helenium	187	Melissa officinalis	220
Valeriana sylvestris	316	Salvia officinalis	220
Bark of the Oak	410	Tops of Mentha piperita	215
Elder	292	Flowers of Anthemis nobilis	338
Elm	375	Borago officinalis	96
Twigs of Solanum Dulcamara	308	Lavandula vera	510
Leaves of Atropa Belladonna	140	Sambucus Ebulus	256
Conium maculatum	185	Petals of Papavar Rhœas	84
Datura Stramonium	110	Rosa rubra	330

Preservation of Medicines. The proper preservation of medicines is an object of the greatest importance to the apothecary. The apartment destined for

a store room should be quite dry, and capable of being ventilated at will, and protected from vermin. As a general rule drugs should be excluded from the light, and not packed away until thoroughly dry. New parcels should not be put in old receptacles until these have been examined, and freed from dust and insects. Barrels and boxes well fitted with movable covers, are suitable for most roots, barks, and woods, and for some herbs, leaves, and seeds. They should be painted externally, and are less liable to harbor insects when varnished inside with a solution of shellac, imbued with aloes, wormwood, or colocynth. *Roots* and *bulbs*, which are to be preserved fresh, should be buried in dry sand. *Aromatic leaves* and those containing alkaloids, *flowers*, most *seeds*, and some *roots*, especially liable to the attacks of insects, should be kept in tin canisters or in light boxes lined with lead, tin, or zinc, or in opaque glass, or earthenware vessels. They should be frequently examined in order to prevent deterioration from insects or moisture. When insects are discovered in a drug, the best means of destroying them, according to Lutrand, is to suspend an open vial containing chloroform in the canister, which is to be closed securely, so that the atmosphere of the vessel may become saturated with the vapour. Cantharides and ergot may be thus treated. Bundles of aromatic herbs, the leaves of which are very friable, as sage, marjoram, &c., should be wrapped loosely in refuse paper, so as to preserve a due proportion between stems, leaves, and flowers. *Gum-resins*, unless in original packages, should be kept in earthen jars or tinned boxes. *Fixed* and *volatile oils* should be kept in canisters or bottles, in a cool dark place, where the average temperature is about 60°. Substances in the form of fecula should be kept in oak barrels, or in canisters, and carefully examined from time to time to detect and remove insects.

Garbling of Drugs. Drugs frequently require to be garbled before they are in a proper state for use. *Senna* is to be separated from the stalks and legumes; *cetraria* from moss, leaves, and sticks; *myrrh* from bdellium, &c.; *gum Senegal* from Bassora gum and a terebinthinate resin; *flaxseed* from clover and garlic seed; *seneka* from ginseng; *spigelia* from the stems and leaves, and both it and *serpentaria* from adhering dirt. Seroons of cinchona should be examined, and the barks assorted before they are put by for use. *Gums* and *gum-resins* should be garbled, and the tears preserved separately.

Weights and Measures. A precise acquaintance with the recognised measures of weight and capacity is essential to the operations of the apothecary. The weights used by him in compounding medicines are the troy pound and its divisions; those by which he buys and sells, the avoirdupois pound and its divisions. The former contains 5760 grains, the latter 7000 grains; so that 11 troy pounds are nearly equivalent to 9 pounds avoirdupois. The troy pound contains 12 ounces of 480 grains; the avoirdupois pound 16 ounces of 437½ grains; eleven of the former being nearly equal to twelve of the latter. The troy ounce is divided, for the use of the apothecary, into 8 drachms of 60 grains each; and the drachm into 3 scruples of 20 grains each. The United States and British Pharmacopœias, that of the Dublin College excepted, recognise the troy weights; and whenever, in this work, any term is used expressive of weight, when not otherwise stated, it is to be understood as being of this denomination. The Dublin Pharmacopœia of 1850 recognises the avoirdupois pound and ounce; dividing the ounce into 8 drachms of 54·68 grains each; and the drachm into 3 scruples of 18·22 grains each.

The measures used by the apothecary, in this country, are the wine pint and the gallon. The wine pint contains 28·875 cubic inches. The weight of a pint of distilled water, at 62° Fahrenheit and 30 inches of the barometer, is 7289·7 grains, or 1 pound 3 ounces 1 drachm 29·7 grains troy, or 1 pound 289·7 grains avoirdupois. The gallon is divided into 8 pints, the pint into 16 fluidounces, the fluidounce into 8 fluidrachms, and the fluidrachm into 60 minims. The weight of a

fluidounce of water is 455½ grains, being 18 grains more than an avoirdupois ounce. A drop is generally though incorrectly considered as equivalent to a minim. Drops vary in size according to the nature of the fluid, and the size and shape of the lip from which they fall. A drop of water nearly equals a minim. A fluidrachm of antimonial wine will make, on an average, about 72 drops, one of laudanum 120 drops, one of alcohol 138 drops, one of ether 150 drops, and one of chloroform more than 200 drops. For a table showing the relative value of minims and drops, see the *Appendix*. The measures recognised by all the British Pharmacopœias are the Imperial gallon of 70,000 grains of distilled water or 277 cubic inches, and its divisions. The gallon is divided into 8 pints of 20 fluidounces each. The fluidounce is divided as that of wine measure, but differs from it in value, containing precisely an ounce avoirdupois or 437·5 grains of distilled water. Measures are employed, both in the United States and British Pharmacopœias, to express the quantity of liquids in nearly all their formulæ.

Liquids are to be dispensed from graduated measures, of which those holding from a fluidounce to a pint are hollow inverted cones; and those holding a fluidrachm, and graduated to every five minims, are cylindrical. For smaller quantities than five minims, a slender tube holding a fluidrachm may be used, having the aliquot parts divided off, and marked with a diamond. Alsop's minimeter, which consists of a slender glass syringe graduated into sixty parts, each equal to a minim, is the most convenient and accurate instrument for measuring fractions of a fluidrachm. Care should be taken to verify these instruments. The following approximate measures are used in prescribing medicines; viz., a wineglassful containing two fluidounces, a tablespoonful containing half a fluidounce, a dessertspoonful two fluidrachms, and a teaspoonful a fluidrachm.

Specific Gravity. The specific gravity of liquids affords one of the best tests of their purity. The instrument commonly used by the apothecary for ascertaining this is *Baume's hydrometer*. This is a glass bulb loaded at one end, and drawn out at the other into a tube on which the scale is marked. That used for alcohol is graduated by loading it until it sinks to the foot of the stem (which is marked zero) in a solution of one part of common salt in nine parts of water. It is then put into water, and the place to which it sinks marked 10° of the scale, which is constructed from these data. The hydrometer for liquids heavier than water is made by loading it, so that in distilled water it shall sink nearly to the top of the stem. The place to which it sinks in a solution of 15 parts of salt in 85 parts of water is then marked 15°, and the scale divided off. For a table exhibiting the value of these scales in specific gravities, see the *Appendix*. Hydrometers are made specially for syrups, acids, and saline solutions. Those for syrups should have a very short tube, graduated from 20° to 40° of Baumé's scale for heavy liquids. The advantage of a short stem is, that the instrument may be used in small vessels.*

The hydrometers commonly imported are so carelessly made that scarcely any two will agree, and little dependence is to be placed on their accuracy. A more certain method consists in weighing the liquid at a uniform temperature in a bottle, the capacity of which, in grains of distilled water, has been previously ascertained. If a bottle is selected which will hold exactly 1000 grains of water at 60°, the weight in grains of the quantity of any liquid which it will hold, will be the specific gravity of that liquid. Such bottles are sold in the shops. If

* For some very interesting observations in reference to the inaccuracy of the existing tables of specific gravities corresponding to the several degrees of Baumé's hydrometer, to the uncertainty of the hydrometer in use, and to a mode of remedying these inconveniences, the reader is referred to a paper by Mr. Henry Pemberton in the *Am. Journ. of Pharm.* (xxiv. i.); and for a good and accurate method of graduating hydrometers to a communication from Dr. W. H. Pile, in the same Journal (xxiv. 310).

one is not attainable, an ordinary vial may be used, and the specific gravity obtained by dividing the weight of the liquid examined by the weight of the water. The operation is rendered more accurate by fitting a smooth cork to the vial, passing a pin transversely through it so as to rest on the lips of the vial, and then cutting a small vertical groove into the side of the cork so as to admit of the escape of the excess of liquid, when the cork is inserted.

Gay Lussac's centesimal alcoholmeter is a very useful instrument, being graduated so as to indicate the per centage of absolute alcohol in any mixture of pure spirit and water.

The specific gravity of a solid is ascertained by first weighing it in air and then in water, and dividing the former weight by the difference between the two. If lighter than water, it should first be weighed in the air, then in air and in water in connexion with a heavier body, which has itself been previously weighed in air and in water; and the weight of the lighter body in the air, should be divided by the excess of the difference between the weights in air and water of the two conjoined, over that of the weights in air and water of the heavier body alone. If the body be soluble in water, its relative weight to that of some other liquid of known specific gravity should be ascertained, in the manner above directed, and this weight multiplied by the specific gravity of that liquid.

The specific gravity of insoluble powders heavier than water, as calomel, may be obtained by introducing 100 grains into a thousand grain bottle, filling it carefully with distilled water, so as to disengage all the air, ascertaining the weight of the contents in grains, subtracting the number of grains exceeding 1000, from the weight of the powder in air, and dividing the latter by the difference. When the powder is soluble or lighter than water, another liquid, as alcohol, ether, or oil of turpentine may be used, the necessary allowance being made for the difference in specific gravity. Very accurate thousand grain bottles are now made in Philadelphia.

Mechanical Division. One of the simplest methods of preparing medicines is their reduction, by mechanical means, to a state of minute division. This is effected by the operations of slicing, bruising, rasping, filing, triturating, grinding, sifting, levigation, and elutriation. When the result is a fine powder, the process or processes employed are called *pulverization.*

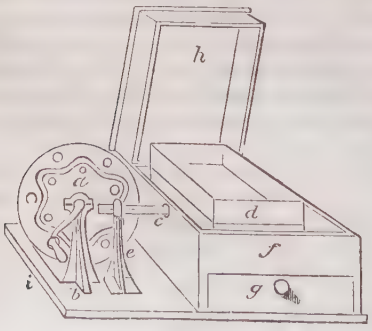
The more important drugs which are sold in the state of powder are pulverized by persons who pursue that occupation for a livelihood. Owing to the readiness with which fraud can be perpetrated in this operation, the apothecary cannot be too careful to place his drugs in honest hands. In sending drugs to the powderer a certain per centage of powder is sometimes required, without regard to the condition of the drugs, as to moisture, extraneous admixture, &c., which per centage often cannot be obtained without the addition of foreign matter. This procedure on the part of the druggist is one of the chief sources of dishonesty in the powderer, and is highly reprehensible. The loss of weight during the processes of pulverization is due to the evaporation of moisture, the unavoidable escape of dusty particles, and the useless residue called *gruffs.* The following statement has been abbreviated from a table prepared by MM. Henry and Guibourt. One thousand parts of the substances mentioned yielded, when pulverized—

Roots.			Florentine orris	850	Cinchona, red	880	
Jalap	940		Rhatany	850	———, yellow	900	
Rhubarb	920		Calamus	840	Cinnamon	890	
Columbo	900		Virginia snake root	800	Angustura	825	
Liquorice root	900		Ipecacuanha	750	*Leaves.*		
Valerian	860		Squill (bulb)	820	Hemlock	800	
Elecampane	850		*Barks.*		Savine	800	
Gentian	850		Cinchona, pale	875	Digitalis	790	

Belladonna	785	Nux vomica	850	*Animal Substances.*	
Senna	720	Colocynth	500	Castor	900
Henbane	530	*Vegetable Products.*		Spanish flies	850
Flowers.		Aloes	960	*Mineral Substances.*	
Chamomile	850	Tragacanth	940	Red oxide of mercury	980
Saffron	800	Opium	930	Red sulphuret of mercury	950
Fruits.		Gum Arabic	925	Arsenious acid	950
Mustard	950	Scammony	915	Sulphuret of antimony	950
Black pepper	900	Catechu	900	Tin	825
		Liquorice (extract)	810		

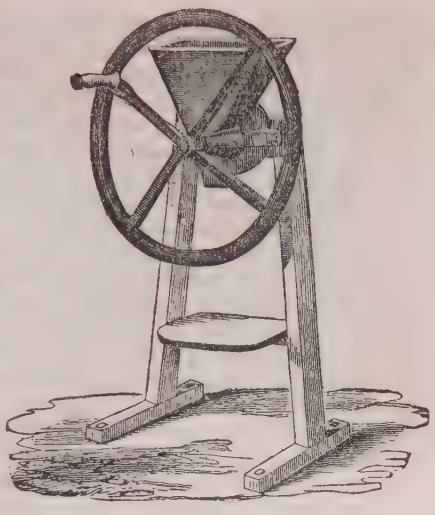
The apothecary often finds it necessary to pulverize drugs in small quantities. For this purpose he should be provided with *mortars* of iron, brass, Wedgwood ware, glass, and marble, sieves of several degrees of fineness, at least one hand mill, one or more cutting knives, a rasp, and a pair of pruning shears.

Contusion should be performed in an iron or brass mortar, the latter being used for astringent substances. The curve of the interior surface of the bottom should be elliptical, and that of the pestle should be of the same kind, but of shorter radius, so that when the pestle stands vertically in the mortar their surfaces may approximate pretty closely for some distance around the point of actual contact. Powdering by contusion is much facilitated by using a large mortar, with the pestle suspended on a spring so as to assist in elevating it. In powdering acrid substances, as well as to prevent loss in those that are dusty, a leathern cover should be attached to the pestle, and held tightly around the edge of the mortar by a circular wooden frame. The operator should guard himself against the fine particles of very acrid substances, like cantharides, euphorbium, &c., by standing with his back to a current of air, and covering his nostrils with a wet cloth. He should be careful not to impede the process by introducing too large a quantity of the material so as to clog the pestle. After the pestle has been in action a certain time, the fine particles accumulate so as to hinder the reduction of the coarser. At this point the sieve should be brought into requisition. *Sieves* for powders are constructed of woven brass wire, and silk cloth (bolting cloth). The best arrangement for the apothecary's use is that known as the box or drum sieve, being cylindrical, with a cover above, and a receptacle below for the powder. After introducing the contents of the mortar, a jerking circular motion should be given to the sieve, without much jarring, so that none but the finest particles shall pass. The coarser portion should then be returned to the mortar to be again acted on. A set of simple sieves, formed by tacking pieces of woven wire, with meshes varying from the twentieth to the fourth of an inch, to square wooden frames, should be provided to prepare drugs for percolation and other modes of solution. When the quantity of material to be sifted is large, recourse may be advantageously had to *Harris's patent sieve*, which has the merits of the drum sieve, with great facility of use. (See *Am. Journ. of Pharm.*, xxv. 31.) A figure of this instrument is given in the margin.



Grinding. The hand mill is exceedingly useful for the coarse comminution of drugs, especially of those which from their acrimony may annoy the operator in the process of contusion. Swift's drug mill (see following page), is one of the most useful and manageable of the kind. It does not answer well for fibrous

drugs like slippery elm and sarsaparilla, unless sliced transversely in short sections.



Trituration is the effect produced where a circular motion, accompanied by pressure, is communicated to the pestle; and is applied most generally to friable substances, or to powders obtained by other means with a view to their further and more regular comminution. The operation is accelerated by alternately increasing and diminishing the circular movements, so as to bring the pestle in contact with all portions of the surface of the mortar. Dover's powder and red oxide of mercury are instances requiring this operation; and in prescriptions for powders, where a variety of substances of variable molecular condition are associated, this process is employed to bring them to a uniform state of division.

Levigation, or *porphyrization* as it was formerly called, is a kind of trituration effected between the flat surfaces of a slab and muller. As the surfaces are equidistant at all parts, a substance subjected to their action has its particles more uniformly divided, than between the curved surfaces of a mortar and pestle. It is usual to moisten the powder with water or alcohol (in which it should be insoluble) so as to bring it to a pasty consistence. The slab and muller are made of glass, porphyry, Wedgwood ware, or marble.

Elutriation bears the same relation to trituration and levigation that sifting does to contusion. It consists in agitating a powder, obtained by those processes, in a large quantity of water, allowing the coarser particles to subside, and pouring off the supernatant liquid, holding the finer particles in suspension, that they may settle separately. The pasty thick mass, left when the clear liquid is decanted, is put into a funnel, and dropped in small portions on a chalk stone so as to form small conical masses. The fineness of the powder depends on its specific gravity, and the length of time which elapses before the liquid from which it subsides is drawn off.

Various means are used to facilitate the operation of powdering. All vegetable substances must be carefully and thoroughly dried. No part of the business of the powderer requires more care than this, especially in relation to those substances which owe their activity to volatile principles. The heat derived from steam, regulated below 100° for aromatic substances, and below 140° for others not injured thereby, is the most appropriate. Resins, gum-resins, and gums must be powdered in cold frosty weather. Tragacanth and nux vomica must be dried in a stove heat, and powdered while hot. The fibrous roots, as liquorice and marshmallow, should be previously cut into thin transverse slices. Agaric is to be powdered by beating it into a paste with water, then drying, and triturating it. Cloves and the aromatic seeds may be ground in a hand mill, and afterwards triturated. Squill and colocynth, the comminution of which is sometimes aided by soaking them in mucilage of tragacanth and then drying, are best powdered in a dry atmosphere, after being thoroughly dried by a stove heat. Camphor requires the addition of a few drops of alcohol. The efflorescent salts may be obtained in the state of fine powder by exsiccation; and those which are insoluble

in alcohol may be precipitated by it, in an impalpable powder, from their aqueous solutions. Vanilla, mace, and other oily aromatic substances, may be rubbed to powder with sugar; magnesia and white lead, by friction on a wire sieve.

Care should be taken, in powdering, to separate previously the inert portions and impurities, and to mix intimately the whole of the powder which is reserved for use. The central woody fibre of ipecacuanha and of other roots, the virtues of which reside in the bark, is to be rejected. The first portions of those barks to which lichens, and the dead epidermis adhere, are inert; as are also the last particles of the fibrous roots and barks.

Ivory, horn, nux vomica, wood, and iron are prepared for pharmaceutic purposes by filing and rasping; guaiacum wood and quassia by turning in a lathe; roots, stalks, and dried herbaceous plants by cutting with a large pair of shears, or with a large knife, fixed in a frame at one end and furnished with a long handle at the other. Tin and zinc are granulated by melting them, and strongly agitating while they are cooling, and carbonate of potassa by stirring with a rod the concentrated solution as it hardens. Earthy insoluble substances are conveniently reduced to powder by levigation.

SEPARATION OF MIXED SUBSTANCES. Various mechanical operations for this purpose are resorted to in practical pharmacy. Some of these have reference to the separation of solids from liquids, others to the separation of one liquid from another.

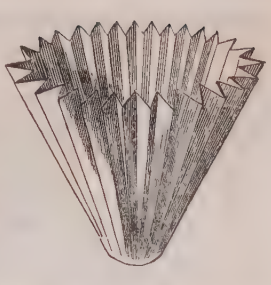
Separation of Solids from Liquids. This includes the processes of decantation, filtration, straining, expression, clarification, &c.

Decantation. Solids may be separated from liquids, when there exists no chemical action between them, by being allowed to subside. The supernatant liquid may then be carefully poured off; or it may be drawn off by a syphon, or separated by filtering. The last operation, or expression by a stronger force, is necessary to separate the whole of the liquid.

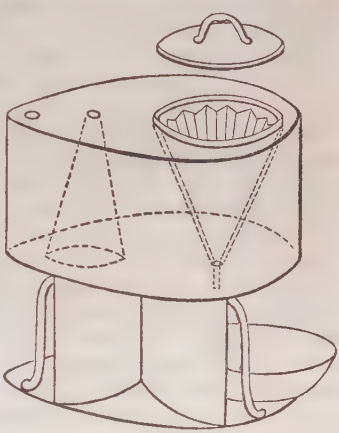
Jars larger at bottom than at the top, and furnished with a lip for pouring, called *precipitating jars*, are sold in the shops, and are proper for decantation, precipitation, and the receiving of filtering liquids. When the decanted liquid is the object of the process, and the powder subsides very slowly, the precipitation may be greatly hastened by the addition of a small quantity of solution of gelatin. Decantation by pouring is facilitated by holding vertically against the lip a glass rod, which attracts and gives a direction to the current, and prevents it from running down the sides of the vessel. The syphon is a tube bent like the letter U having one limb longer than the other. When it is filled with liquid, and the shorter end is inserted in the fluid to be decanted, a current is established towards the longer limb owing to the greater weight of its contents, which continues as long as the shorter limb is kept below the surface of the liquid.

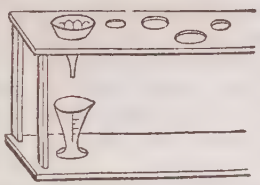
Filtration consists in pouring a mixture of solid and fluid matter on a porous surface, called a filter or strainer, which admits of the passage of the fluid only, and is designed either to clarify the liquid, or to separate the solid from the associated liquid by washing and draining.

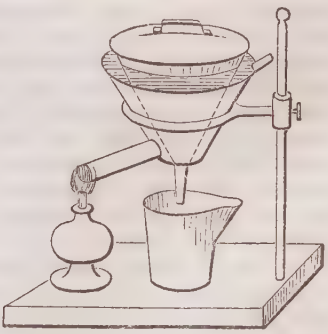
Filters or strainers are made of unsized paper, cotton, linen, and woollen cloth, charcoal, glass, and sand. The apothecary should be provided with several kinds of filtering paper, one of which should be white and free from matter soluble in dilute acids, especially oxides of iron. Paper filters are *plain* or *plaited*. The plain filter is made by folding a square piece of paper twice, so as to bring the four corners together, and then separating one of the layers from the other three so as to form a hollow cone, which is inserted in a funnel. Such filters are best for precipitates; but when rapid filtration is required, the plaited filter, by presenting a much greater extent of surface, and numerous channels for the descent



of the liquid, is to preferred. The paper is folded into 32 triangular surfaces, all the points meeting in the centre, and the edge presenting a zig-zag outline as in the figure. In some cases it may be necessary to place a small cone of the same material outside of the large one to strengthen it. When the liquid is too viscid to pass readily through paper, a cotton or woollen bag of a conical shape may be used. Cotton flannel with a thick nap is well suited for syrups. Acids may be filtered through a layer of fine siliceous sand, supported in the neck of a glass funnel by pieces of glass gradually decreasing in size. Castor oil, syrups, and oxymels may be readily filtered through coarse paper, made entirely of woollen shreds; but the best material for fixed oils is hatters' felt, in the conical form in which it is prepared in the making of hats. This may be attached to a tin ring, and suspended over a suitable vessel. Melted fats, resins, wax, and plasters may be *strained* through muslin stretched over a square frame, or a hoop. Hair cloth or wire gauze is better suited for plasters than muslin. Small sieves of fine bolting cloth serve for straining emulsions, decoctions and infusions; and a temporary strainer for these purposes may be made by fastening a piece of muslin between the upper and lower parts of a common pill box, and then cutting off the ends so as to leave the rim only of the box around the muslin. The filtration of viscid substances is facilitated by heat. Filtration through bone black is practised for muddy or dark coloured liquids. Much inconvenience is often experienced in the filtration of hot saturated saline solutions, by the cooling of the liquid, and consequent crystallization of the salt, in the filter and neck of the funnel. To obviate this, the tin apparatus represented in the above wood cut was contrived by Professor Hare. The vessel is filled with hot water, which is kept at a boiling heat by a spirit lamp placed under the cavity having the shape of an inverted funnel. A glass funnel with a filter is placed in the other cavity, and the liquid passes through rapidly. In filtering alcoholic solutions, it is necessary to protect the liquid from the flame of the lamp, and for this purpose the partition underneath has been added. No apothecary should be without this useful apparatus. The arrangement of Dr. Hare has been simplified by having a funnel with double sides, as in the figure, with a hollow cylindrical projection at the lower part, to







which a spirit lamp heat may be applied, while the funnel is supported on a lamp stand; the space between the sides being filled with water. Frames of various sizes for holding funnels and filters will be found very useful; the wood cut represents the one commonly used. The efflorescence of saline solutions on the edge of the filtering paper may be prevented by dipping it in melted tallow or lard.

The filtration of liquids which are altered by exposure to the air requires much caution. A very simple method of accomplishing it is to insert a slender tube of glass into the funnel, long enough to reach below the neck, while the upper part is nearly as high as the top of the funnel. The space between the tube and the neck must be filled with bits of glass and fine sand so as to form a good filtering bed; the liquid is then poured in, and the top of the funnel covered with a plate of glass. If this be luted on, and the funnel luted into the neck of a bottle, the process will be performed with perfect accuracy. Another way of performing this operation, in relation both to liquors altered by the carbonic acid of the air, and to those which are very volatile, as ethereal and ammoniacal solutions, consists in covering the funnel with a sheet of tin foil, or moist bladder, and putting a small tube within and against the side of the funnel, extending nearly to the top, so as to form a communication between the atmosphere of the receptacle and that of the funnel. By such an arrangement ordinary filtering through paper can be conducted with perfect success with ether or solution of ammonia. The filtration of large quantities of liquids is facilitated by having a self-supplying apparatus, so that the level of liquid in the filter may be constant. This is effected by inserting a tube, with a bore of a quarter of an inch, through the cork of a large bottle containing the liquid to be filtered, and supporting the bottle in an inverted position over the filter, as at page 783, so that the tube shall dip slightly below the surface of the liquid. As this descends its place is supplied from the bottle above. Another arrangement, in which a syphon is used, is figured in the following page.

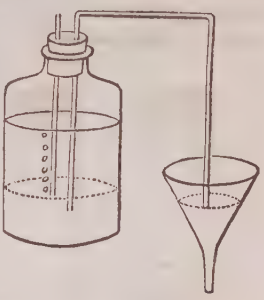
Expression is required to separate the last portions of tinctures and infusions from the dregs. A screw-press is used for this purpose. The substance to be pressed is put into a cylinder of strong sheet tin, the sides of which are pierced with small holes. This is placed on a square tray of tin having a lip for pouring. A block of wood, which fits into the cylinder, like a piston, is placed on the top, and the whole is put under the screw-press, the pressure of which is gradually brought to bear upon it.

This press is to be used for expressing the juices of fresh plants, which, previously to being pressed, must be well beaten in a mortar, water being added to those which are hard and dry. The juices of succulent fruits, as strawberries, raspberries, &c., are most advantageously extracted by filling several strong flannel bags about two-thirds full, without bruising them, laying these in a pile on a suitable tray, placing a strong block over the whole, and gradually bringing the press to bear upon them. The expressed oils are obtained by bruising the seeds which contain them, and enclosing the bruised mass in strong bags, which are placed in a firm hollow frame, and subjected to strong sudden pressure by driving up a wedge. Expressed oils are clarified from mucilage by boiling them with water.

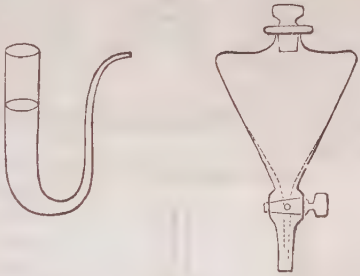
The *clarification* of liquids may be effected by the addition of some coagulable substance, such as milk or an aqueous solution of ichthyocolla. The white of an egg beaten up with water will coagulate with a gentle heat, and clarify any liquid with which it has been mixed. The vegetable acids will clarify many of the expressed juices of plants; and the juice of sour cherries will cause the complete separation of the pectin of currant and raspberry juice, so as to fit them for syrups.

Precipitation is sometimes mechanical, as in the process of *levigating* and *elutriating* chalk, and sometimes chemical, as in the preparation of the precipitated

carbonate of lime by decomposing chloride of calcium. When a precipitant is directed to be added until no further precipitation takes place, the fact may be ascertained by taking a drop of the liquid on a glass plate, and trying it with the precipitant. The formation of a precipitate is often much assisted by agitation, or by heat. The separation of the supernatant liquid from the precipitate is most effectually accomplished by means of a syphon. When the liquid is a saline solution, it is necessary to wash the precipitate until the water exhibits no trace of the salt. In doing this great care must be taken to select the purest and clearest water, and the ultimate drying of the precipitate must be performed in a filter, or on a porous stone.



The apparatus figured in the margin is very convenient for procuring a constant and gentle stream of water, in washing precipitates and in clearing crystals of the impurities of their mother-water. It consists of a syphon having legs of equal length, one of which is inserted in an air-tight bottle nearly filled with water, and the other dips into the funnel. A straight open tube is also inserted in the bottle, the lower end of which is about half an inch or an inch above the end of the syphon. It is obvious that the water will run from the syphon no longer than till the water in the funnel is level with the end of the straight tube. The same effect may be produced by using an inverted bottle and tube, as described in the preceding page.

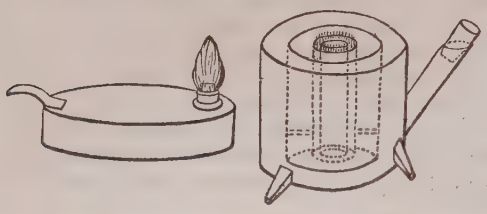


Separation of Liquids. Liquids which have no chemical affinity, and differ in specific gravity, may be separated by allowing them to remain at rest in the separating funnel represented in the annexed figure, and then drawing off the heavier fluid. Another very convenient method of separating fluids is by means of the *separatory* figured in the wood cut in the margin. The last drops of the heavier fluid may be drawn off by means of this instrument.

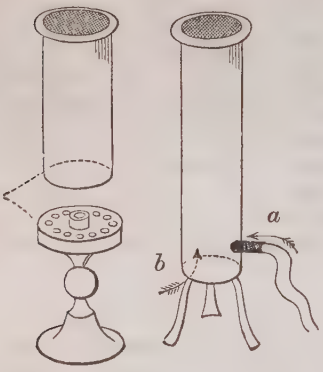
Application of Heat. The most efficient and economical means of obtaining heat is a subject of great importance to the pharmaceutist, on account of the variety of processes in which it is required.

With the small *furnaces*, which are now made of fire clay, of various patterns and sizes, almost all the operations of the laboratory which require heat can be performed. The fuel used is charcoal, although anthracite will burn in those of a larger size, and is to be preferred where a uniform heat is necessary for several hours. The apothecary should be provided with a complete set of these useful utensils, including one with a dome for a reverberatory furnace. By adding a pipe several feet in length to this, and urging the fire with a pair of double bellows, the heat may be raised to that of an air furnace. A small pipe of sheet iron with a cone at the lower end, as in the figure, to fit on the furnace, will be found an excellent means of obtaining an intense heat in those of the smallest size. For operations on a smaller scale, a convenient means of obtaining heat is by alcohol lamps. Alcohol burns without smoke or smell, and is almost as cheap a fuel as oil, to which it is on every other account preferable. The

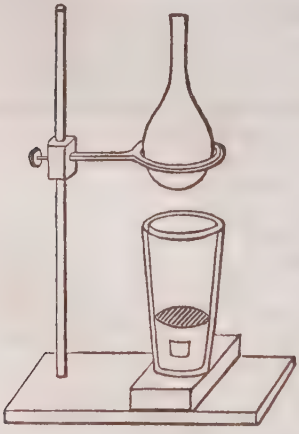
annexed figures represent the usual form of spirit lamps. The larger one will be found very useful in heating spatulas for spreading plasters.

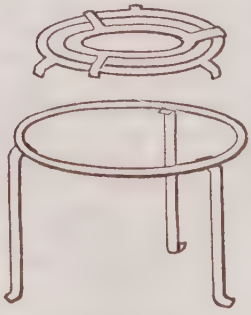


Gas burners afford a yet more eligible and economical means of applying heat than alcohol lamps. When coal gas is mixed with a due proportion of atmospheric air before ignition, it burns with a bluish flame and produces but little if any smoke. The gas burner consists of a cylinder of sheet or tinned iron from 2 to 4 inches in diameter, and 6 or eight inches long, open at the inferior end, while the upper end, which is slightly flared, is covered with a piece of number 70 brass wire gauze, fastened on with wire. This burner is supported vertically over an ordinary gas jet in any convenient position, and the gas on being allowed to issue into it, rises from its superior levity, mixes with the air, and is ignited by means of a taper above the gauze. The heat can be managed by regulating the flow of gas, and by using burners of different sizes. The left of the two figures in the margin exhibits this arrangement. That on the right, in which a tube conveying gas (*a*) enters the cylinder horizontally while the air passes in at *b* below, is an arrangement suggested by Dr. Bridges, and may be adapted to the common bat-wing or fish-tail gas burner.



For supporting the substance to be heated, iron tripods, of various heights and sizes, must be provided. These should be furnished with sets of concentric rings, as in the figure, for vessels of different sizes. A very convenient support is the stand and ring figured in the wood cut, which will answer for a spirit lamp, or for a small furnace made from a black lead crucible, as in the figure.





The temperature required in pharmaceutical processes seldom exceeds a red heat; and the vessels used are *crucibles* of silver, porcelain, Wedgwood ware, black lead, and fire clay (Hessian crucibles). Silver is used for the fusion of potassa, porcelain for nitrate of silver, and black lead and Hessian crucibles for the metals, glass of antimony, sulphuret of potassium, and the ordinary operations which require a great heat. They are each liable to objections; silver fuses too readily; porce-

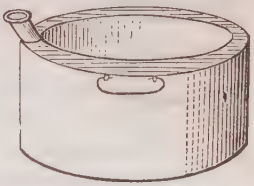
lain and Wedgwood ware do not bear sudden changes of temperature; black lead, which bears these changes, is destroyed by saline substances, and burns in a current of air; and the Hessian crucibles are so porous as to absorb and waste much of the fused substance. The crucibles should be covered with a lid or an inverted crucible, and should be supported at a little distance from the bottom of the grate, and surrounded and covered with ignited coals.

Liquefaction is performed in open earthen, copper, or iron vessels, and care must be taken not to raise the heat so as to char or inflame the substance.

A sand bath is an indispensable part of the pharmaceutic apparatus. It is usually an iron pot, or a shallow vessel of sheet iron capable of holding sand to the depth of four or six inches. It serves to regulate the action of the heat on vessels which do not bear a rapid change of temperature. It is sometimes heated to a red heat as in preparing the mineral acids, though more frequently used for the evaporation of saline solutions and vegetable juices.

Evaporation is one of the most important operations of the pharmaceutical laboratory, and on its proper management depends the value of a large number of preparations. The readiness with which organic matter is modified by direct heat, has caused the invention of various means and apparatus to effect evaporation under the most favourable circumstances, as with the *water bath, steam bath, solution bath, vacuum pans,* etc.

The *water bath* is to be used in all cases where a heat above that of boiling water would be injurious. A convenient one consists of two copper vessels, the upper one of which is well tinned. It is still more convenient to have the water bath constructed as a hollow vessel with one opening at the top for the escape of steam and for the introduction of the water, as in the figure. By inserting a cork in the aperture, the contents of the inner vessel may be poured out as from a dish without spilling the water. It may be made of tinned iron, or preferably of tinned copper. Where a temperature above that of boiling water, and not exceeding 228° is required, the water bath may be filled with a saturated solution of common salt, sulphate of soda, or chloride of calcium, the last mentioned salt communicating a heat as high as 240° when desired.



Steam baths are by far the most useful and easily regulated of the arrangements for indirect heating. When steam heat is applied in a double-sided vessel like the water bath, it is called a steam jacket, and must have two openings, one for the ingress of the steam, the other for the exit of the air, and for drawing off the condensed water. When the steam jacket is strongly made, a heat of 300° may be readily commanded. A more economical and easily applied arrangement consists in placing a coil of tube in the vessel containing the liquid to be evaporated, and causing a strong current of steam to circulate through it. For further remarks on apparatus for evaporation, including the vacuum pan, see *Extracts.*

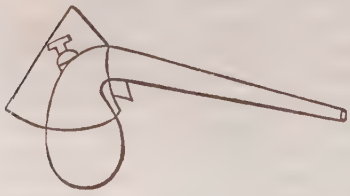
The apothecary should be provided with a set of evaporating vessels, of porcelain, glazed iron, tinned iron, and copper. For metallic solutions vessels of Berlin porcelain are the most useful. In most cases of surface evaporation, where the product is uncrystallizable, the process should be hastened by stirring.

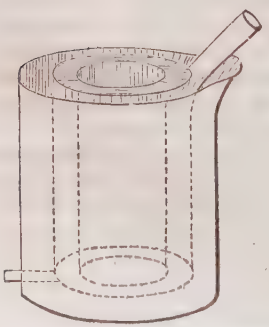
Distillation consists in vaporizing a fluid in one vessel, and conducting the vapour into another vessel, where it is condensed and collected. The process is used for separating a liquid from solid substances which it may hold in solution, or with which it may be mixed; for separating a more volatile liquid, as ether and alcohol, from one less so; for impregnating a liquid with the volatile principles of plants to the exclusion of other principles, as in the preparation of aromatic spirits and waters; and for separating by means of aqueous vapour, the

essential oils and volatile proximate principles of the vegetable kingdom. The process for separating one liquid from another is termed *rectification*. When in the last two processes, the distillation is repeated with the same liquid and a fresh quantity of the plant, the operation is called *cohobation*. Distillation is also used for obtaining the volatile products which result from the decomposition by heat of substances of animal or vegetable origin. The oils which are obtained in this manner are called *empyreumatic oils*. Sometimes the result is an acid, as the succinic acid, and sometimes a volatile alkali, as in the destructive distillation of animal substances.

The *common still and worm*, the vessels in general use for *distillation*, are too well known to need description. A convenient still or alembic for small operations, which may be heated by a spirit lamp, is figured in the wood cut. The top of the head is kept filled with cold water, and all escape of vapour is prevented by having an inner ledge to the still, and filling the space in which the head fits with water. The condensation of all the vapour is secured by adapting a worm, or a long tube to the apparatus. The boiler of this still may hold one or two gallons, and it will be found a very useful means of recovering the alcohol in making alcoholic extracts. It may easily be converted into a water bath by fitting on the top of the boiler, a vessel of convenient form. These stills are easily adapted to the common cylindrical anthracite stoves, used for heating, by means of a sheet iron collar, through which the boiler of the still is made to pass, and on which it is supported.

When the common glass retort and receiver are used for the distillation of liquids, care should be taken not to apply the luting until the atmospheric air is expelled, unless the receiver has a tubulure for its escape. The chief objects to be aimed at are to keep the body of the retort hot, and the neck and receiver cool. A hood of pasteboard or tin, as represented in the figure, will much facilitate the former; and the latter will be gained by keeping the neck and receiver wrapped in wet cloths, on which a stream of cold water is kept running. This may be conveniently done by means of a syphon made by dipping one end of a strip of cotton or woollen cloth in a vessel of water, and allowing the other end to hang down upon cloths bound loosely around the receiver and the neck of the retort. The apparatus figured in the margin is one of the best for the condensation of ethereal vapour, as in regaining the ether in the process for making ethereal extracts. It consists of a close hollow cylindrical tin vessel, having a large neck above for the insertion of the neck of a retort or a tube; and a small tube below for the escape of the condensed ether. This vessel sits in a large one open at top, which is kept filled with cold water, constantly renewed by a tube descending to the bottom.





When certain liquids are boiled in glass vessels, sudden jars or succussions are apt to occur,

which are often inconvenient, and sometimes interrupt the process. These may be obviated by giving a metallic coating to the lower portion of the interior surface of the vessel. Mr. Redwood recommends for this purpose the process of Drayton. He introduces into the flask or retort as much ammoniacal solution of silver as may cover the part to be coated, precipitates the silver by the addition of essential oils, and afterwards thoroughly cleanses the vessel by boiling it in successive portions of alcohol, until the silver becomes perfectly bright and all smell of the oil is removed. A coating of platinum may also be obtained, though less perfect, by precipitating a solution of the chloride of that metal by formic acid and afterwards boiling. (See *Am. Journ. of Pharm.* xx. 333.) These succussions are moderated and sometimes prevented by putting in the retort a number of small angular fragments of glass or quartz crystal. The most convenient and effectual apparatus for distillation in small quantities, is the flask and Liebig's condenser, figured in page 793; and with such an arrangement the contents of the flask are less likely to be driven over, so as to mix with the distilled liquid.

When the object of distillation is to preserve the residuum, and this is liable to injury from heat, as is the case with vegetable extracts, the operation is best performed in vacuo. For this purpose the still and recipient are made so as to form an air-tight apparatus, and the latter is furnished with a stop-cock which is kept open until the whole of the atmospheric air is expelled by the vapour. It is then closed, and a vacuum formed and maintained in the recipient by surrounding it with cold water. The distillation is carried on in this manner at a much lower temperature than under ordinary circumstances, and the heat may be applied by a water or steam bath, with greater certainty of obtaining an uninjured product. For a more extended account of vacuum apparatus, see *Extracts.*

Sublimation. The vapours of some volatile solids have the property of condensing into the solid form, either in mass or in a state of minute division. The operation in which this occurs is called *sublimation.* When the product is compact it is called a *sublimate*, when slightly cohering it is called *flowers.* The operation is generally performed in a sand bath; and the apparatus consists of two vessels fitting each other, one being inverted over the other. The shape, size, material, and depth of the vessels, and the degree of heat to be applied are regulated by the nature of the substance operated on. For the details of this process see the articles *corrosive sublimate*, *camphor*, and *benzoic acid.*

Lutes. The most precious material for the chemist is glass, the transparency, insolubility and hardness of which fit it for almost every purpose. It is often necessary to strengthen it by means of lutes which will bear a heat at which glass would soften; and the application of lutes for this purpose, and for securing the junctures of tubes and vessels, is an important part of the pharmaceutic art. Those lutes which are required for coating vessels exposed to a great heat, are made of Stourbridge clay. The clay is made into a paste with water, mixed with chopped straw or cut hemp, and successive coats applied as they become dry. Dr. Hare recommends the fine wool-like turnings of iron for this purpose instead of chopped straw. Earthenware vessels may be rendered impervious to air or vapours by brushing over them a thin paste made of slaked lime and a solution of borax containing an ounce to the half pint. This is allowed to dry, and the vessel is then coated with slaked lime and linseed oil, beaten till the mixture becomes plastic. Earthenware retorts, thus coated, may be safely used more than once, the coating being renewed every time.

Fat lute is applied to the joinings of apparatus to prevent the escape of corrosive vapours. It is made like glaziers' putty, pipe clay being substituted for whiting. It will bear a considerable heat, and great care must be taken that

the part where it is applied be perfectly dry. If it be exposed to heat, slips of moistened bladder must be wrapped around it and secured with twine.

Roman cement and plaster of Paris may be applied in the same manner as fire-clay. When used for securing the joinings of apparatus a coating of oil or wax will render them air-tight.

A very useful lute is formed by beating the white of an egg thoroughly with an equal quantity of water, and mixing it with some slaked lime in the state of fine powder so as to form a thin paste. This must be spread immediately on strips of muslin and applied to the cracks or joinings intended to be luted. It soon hardens, adheres strongly, and will bear a heat approaching to redness without injury. A leak in this lute is readily stopped by the application of a fresh portion. Solution of glue, or any liquid albuminous matter, may be used in place of the white of eggs.

An excellent cement for surfaces of iron consists of one part of sulphur, two of sal ammoniac, and eighty of iron filings, mixed together and slightly moistened. It is rammed or caulked into the joints, and solidifies perfectly in time.

White lead ground in oil is an excellent cement for broken glass. Spread upon linen it forms a good coating for a cracked surface, but dries slowly. Strips of bladder macerated in water, adhere well to glass and are very useful.

A mixture of whiting and paste or gum water, spread upon strips of paper, forms an excellent luting for joinings not exposed to acrid vapours or a great heat.

A useful lute is formed by spreading a solution of glue on strips of cloth, and coating them, after they are applied, with drying oil.

Linseed meal, beaten into a uniform mass with milk, lime water, rye paste, or thin glue, and applied in thick masses, adheres well; and when dry will resist most vapours.

Cap cement is made of six parts of resin, one part of yellow wax, and one of Venetian red. It is a very useful cement for fastening metals or wood to glass, and for rendering joints impervious to water. *Soft cement* is used for the same purposes, and is made of yellow wax, melted with half its weight of turpentine, and coloured with a little Venetian red. It is very useful for rendering the stoppers of bottles perfectly air-tight.

Chemical Operations. Some of the chemical processes, conducted by the apothecary, have been explained in the former part of this Introduction. It remains to notice others in constant or frequent use.

Solution. The act of solution, in which solid substances assume the fluid state through the agency of liquids, is one of the most important operations of practical pharmacy. The process has received a variety of names according to the mode of applying the menstruum and the degree of heat employed; as *maceration*, *infusion*, *digestion*, *decoction*, *displacement* or *percolation*, and *circulatory displacement.*

Two classes of substances are the subject of solution; those which dissolve entirely in the menstruum, as salts, gum, &c., and those which consist of soluble and insoluble matter, as roots, leaves, barks, etc. The former yield *simple solutions;* the latter *infusions*, *decoctions*, *tinctures*, *wines*, etc. Solution is sometimes accompanied by chemical reaction, as when metals are dissolved in acid solutions. Mechanical division facilitates solution by increasing the extent of surface. Heat as a general rule favours solubility. All aqueous solutions of solid bodies are denser than water. A solution is said to be saturated when the dissolved substance ceases to be taken up at common temperatures. A saturated solution of one salt will dissolve other salts, a fact taken advantage of in purifying nitre, and other saline bodies in powder, by percolating them with their own

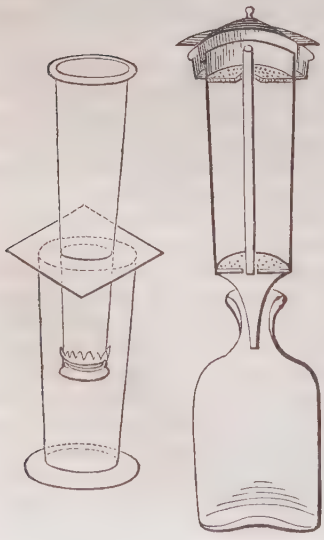
saturated solutions. Rapid solution when unaccompanied by chemical reaction causes a reduction of temperature; hence in such cases, where dense solutions are required, heat should be employed to counteract that effect. In dissolving a substance wholly soluble in the amount of liquid used, a convenient method is to reduce it to powder in a mortar, add the liquid in portions, and decant until the whole is dissolved. Capsules and flasks are the most suitable vessels for performing solution when heat is necessary. If the solid softens before dissolving, as in the case of the extracts, a capsule should be used, with constant stirring. When effervescence occurs a flask should be used inclined to one side to avoid loss; or, if the capsule be employed, an inverted funnel should be placed over it. When the quantity of a substance is large, and time permits, the process called *circulatory displacement* affords the best means, especially in making saline solutions. This is performed by suspending the salt enclosed in a piece of gauze or other porous tissue near the surface of the liquid. The solution proceeds rapidly; as the liquid in contact with the salt, by becoming saturated and heavier, descends to give place to less saturated portions, so as to cause a kind of circulation of the solvent. This process is applied in the arts, and has been suggested in making infusions and tinctures.

Infusion is the subjecting of a substance containing soluble principles to the action of a menstruum, which is usually water. Hot infusions are made by pouring boiling water on the substance, and allowing it to remain in a covered vessel till cold. Cold infusions are made with cold water, and require several hours to attain their full strength. *Maceration* is the term employed to denote the action of liquids upon medicines, when allowed to remain upon them for some time, at a heat from 60° to 90°. *Digestion* is the name given to the same operation, when conducted at a temperature between 90° and 100°. This process is sometimes effected at higher temperatures, but the heat is uniform during the operation, and always below the boiling point of the liquid. It is commonly performed in glass bottles or flasks, and a common fire or stove heat is employed. When digestion is performed with alcohol and ether at temperatures near their boiling points, the vessel should be connected with a refrigerated worm or other condenser to save the vaporized portion. Soubeiran places the worm above the digesting vessel, so that the condensed fluid runs back at once into the vessel.

Decoction, or boiling, is sometimes employed in extracting the virtues of plants; but is often disadvantageous, as most of the proximate principles of vegetables are altered by it, especially when long-continued. When it is practised, the ebullition should generally be continued for a few minutes only, and the liquid be allowed to cool slowly in a close vessel. For further remarks on infusions and decoctions see the preliminary notices to these classes of preparations.

Lixiviation is a process used to separate a *soluble* from a porous *insoluble* body. It consists in placing the substance to be lixiviated in a vessel, the bottom of which is covered with straw, sand, &c., pouring water upon it, allowing the water to remain until saturated, and then drawing it off through an opening at the bottom of the vessel. It is found that if fresh water is poured on without disturbing the mixture in the vessel, it does not mix with the liquid already there, but percolates the solid particles, driving the saturated liquid before it; so that, for example in lixiviating wood ashes, if a gallon of water had been poured on the ashes, and allowed to become saturated with the alkali, we shall obtain, by this mode of proceeding, a gallon of strong ley, and immediately thereafter the water will become almost tasteless. This fact has been applied to the service of the pharmaceutist, and has led to some valuable improvements in the mode of extracting the medicinal qualities of plants.

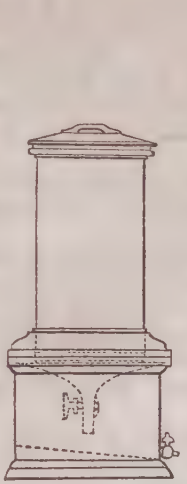
The operation referred to is called by the French the *method of displacement;* but the terms *percolation* for the process, and *percolator* for the instrument in which it is performed, are more appropriate in our language. The figure in the margin represents *Boullay's filter,* or percolator, constructed on this principle. It consists of a long tin vessel, nearly cylindrical, but narrower at the lower end, which has a funnel shaped termination, for the purpose of being inserted in the neck of a bottle. A metallic plate, or diaphragm, pierced with holes, like a colander, and having a handle in the centre, fits accurately in the lower part of the cylinder. Upon this, previously covered with a thin layer of carded cotton, tow, or a piece of cotton flannel, is placed the substance upon which it is intended to operate, and which should be coarsely powdered or ground in a mill. It must then be saturated with the menstruum, which is done by pouring on the liquid from time to time until it will absorb no more, and then allowing them to remain for a few hours in contact. On the top of the powder is placed another similarly pierced plate, and fresh portions of the menstruum are gradually and successively added, until the process is completed. The first portion, that with which the powder was mixed, flows off very highly concentrated, while the next is much less so, and the successive infusions rapidly become weaker. A stop-cock near the lower end of the instrument, as represented in the second figure, will be convenient for regulating the discharge of the fluid. A single example will show the value of this process. The Messrs. Boullay, by subjecting four ounces of bruised cinchona to percolation with half a pint of water, and then adding four half pints in succession, obtained the following results.

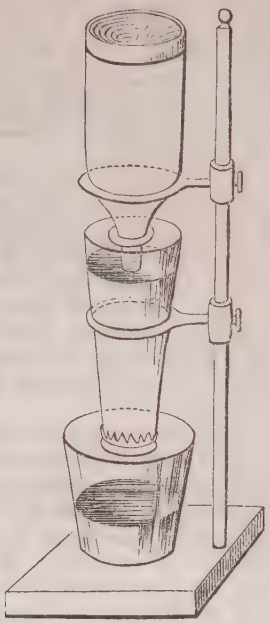


1st	Half pint yielded	3 drs.	48 grs.	dry extract.
2d	Do.	" 1 dr.	5 grs.	Do.
3d	Do.	"	15 grs.	Do.
4th	Do.	"	9 grs.	Do.
5th	Do.	"	7 grs.	Do.

Cylinders 14 inches long by $2\frac{1}{2}$ in width at the base, 14 inches by 4, and 17 by 6, are convenient sizes for ordinary use. Queensware percolators are now to be procured from the druggists, and are useful for acid or astringent solutions. In a large proportion of the cases of percolation small vessels only are required. The common glass cones, used as lamp glasses, figured in the margin, when inverted, with a piece of close canvass or flannel tied over the smaller end, form convenient percolators; and their transparency enables the operator to assure himself that the powder is properly stratified before adding the menstruum. A tin percolator, formed with a double rim into which the rim of the lid is inserted, (the

interstice being filled with water so as to make an air-tight juncture,) and furnished with an open vertical tube extending from the top through the diaphragm below, is used when volatile liquids, as ether, alcohol, and spirit of ammonia, are used as menstrua. It is figured in the preceding page. When it is wished to operate upon a fine powder, it will be found advisable to increase the height of the column of liquid by making the top of the cylinder air tight, and inserting a tin tube several feet long, which must be kept filled with the liquid. All the substantial advantages of this method may, however, be generally obtained without pressure, by using the filter of Boullay. For operating on very small quantities of a substance, an adapter or the neck of a broken retort may be used, by loosely stopping the lower and smaller end with a piece of cotton.





Soubeiran has adapted to Boullay's filter a receiver of tin, from which the filtered liquor may be drawn off by a stop-cock at the most dependent part. An apparatus of this kind is represented above. One of the most important points in conducting the displacement process is to keep the ingredients constantly saturated, with a stratum of the displacing liquid over them. To avoid the necessity of constant supervision to effect this, the arrangement in the right-hand figure above may be used. An ordinary bottle containing the menstruum, with a tube of a quarter of an inch bore passing through the cork, is inverted over the percolator with the end of the tube dipping in the liquid above the ingredients.

Crystallization. Numerous chemical substances, in becoming solid when their solutions are evaporated, take on certain regular forms. The bodies having such forms are called *crystals*, and the process for obtaining them, *crystallization*. The most usual method is by the evaporation of solutions, either spontaneously, or by the application of heat. The extent to which the evaporation should be carried depends on the solubility of the substance. The proper degree of concentration is attained, when a drop of the solution removed to a cool glass plate deposits well formed crystals. When set aside to crystallize, a solution should not be disturbed until the deposition ceases. The crystals are large in proportion to the slowness of the cooling of the solution, to effect which the vessel is sometimes set in the drying closet, and sometimes left to cool with the sand bath. The deposition of crystals is facilitated by suspending some insoluble substance, as wood, or sheet lead in the solution, or crystals of the same substance, which are thus increased in size. When it is desirable to have small acicular crystals, the solution should be cooled rapidly and stirred constantly meanwhile.

Crystallization is one of the best means of purifying many substances; the im-

purities remaining wholly or chiefly in the residual liquid called *mother water*. Fine silky crystals which retain their mother water by capillary attraction, must be dried by strong expression in a linen bag. The finest silky crystals may be entirely freed from their adhering liquid, by placing them in a funnel which fits closely to one of the necks of a double mouthed bottle, and fitting a tube to the other, through which air is drawn. The current of air, in passing through the funnel, carries the water with it, and dries the crystals perfectly.

The operations which require a heat greater than that used in digesting are *liquefaction*, *fusion*, *calcination*, *ustulation*, *incineration*, *distillation*, *sublimation*, and *reduction*.

Liquefaction is the melting of those substances that become soft previously to fusion, as wax, tallow, plaster, &c. The heat employed is always below that at which charring takes place.

Fusion is the melting of those substances which pass immediately from the solid to the fluid state. It is employed in pharmacy in preparing the nitrate of silver and caustic potassa for casting into cylinders. The former must be melted in a porcelain, the latter in an iron crucible. The moulds in which they are cast are formed of two thick plates of cast iron, with semi-cylindrical grooves that fit accurately to each other. Fusion is also used in preparing the glass of antimony.

Calcination is a term applied to the changes produced in mineral substances by intense heat, not attended with fusion, and leaving a solid residue, and is often synonymous with oxidation. The term *ustulation* is restricted to the metallurgic operations of roasting ores, to drive off the volatile matters, as arsenic, &c. Calcination is often used to express the ustulation or burning of carbonate of magnesia. This is to be performed in an earthen vessel at a red heat. Exposure to the heat of a potter's furnace during the burning of the kiln, is an excellent mode of performing the operation. More commonly the carbonate is burnt in an iron pot, which is objectionable, as the heat soon oxidizes the iron, and the oxide scales off and mixes with the magnesia, which is seldom free from iron when prepared in this way.

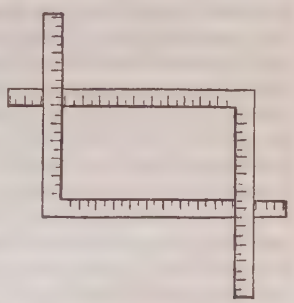
Incineration, as the name expresses, is the operation of burning substances for the sake of their ashes. It is performed in obtaining phosphate of lime—the Cornu Ustum of the London Pharmacopœia. The bones are burnt in an open fire until all the combustible matter is consumed.

Reduction is that operation by which certain binary compounds of the metals are brought to the metallic state, by heating them alone, or with some substance capable of attracting the combined substance and setting the metal at liberty. Arsenious acid is thus reduced by heating it with charcoal, and oxide of iron, in the state of powder, by heating it in a current of hydrogen. When, in the reduction of metallic compounds, some third substance interferes with the process, as silica, a substance capable of combining with this is added called a *flux*.

Dispensing of Medicines. A large portion of the operations of the apothecary is performed in the shop extemporaneously. In dispensing medicines from the counter, he is continually called upon to put his previous knowledge in practice, and often to substitute extemporaneous for the regular officinal formulæ. There is no part of his business which requires, for its proper performance, so much ready knowledge and so accurate a judgment. A few directions suggested by running the eye over the list of preparations of the Pharmacopœia, may be found useful.

It may sometimes be necessary for the apothecary to make extemporaneously an aromatic water, not usually kept in the shops. In this case he is to prepare it by rubbing two drops of essential oil with from four to six grains of carbonate of magnesia for every fluidounce of water, and filtering.

It is sometimes desirable to apply plasters prepared from the narcotic herbs. These may be made extemporaneously by mixing the soft extract of the plant, with about twice its weight of melted adhesive plaster. The most suitable material on which to spread plasters is soft white leather. A margin of half an inch should be allowed to remain around the plaster. The plaster iron or spatula may be heated over the large spirit lamp, figured in page 776. A skilful apothecary will be able to spread the plaster uniformly and evenly, without overheating it so as to corrugate or penetrate the leather. A convenient instrument for determining the size and preserving a straight edge, consists of two squares made of tin and graduated to inches, as in the annexed figure; or pieces of paper may be cut out and pasted on the leather so as to enclose a space of the required dimensions. The plaster should first be melted on a piece of brown paper, and then transferred to the leather, in order to prevent its being applied at too great a heat. For all the officinal plasters the apothecary should have small tin trays open on one side, on which to melt them. If the plaster to be spread is a very large one, it is better to liquefy the material in a capsule, and add it to different parts of the leather as it is wanted, till the whole is covered. For the description of an apparatus for spreading plasters, see *Emplastra.*



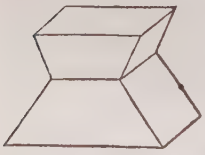
Decoctions and infusions are often ordered in prescriptions in the quantity of a few ounces. A very convenient vessel for preparing them is the common nursery lamp, which consists of a cylindrical vessel, open at one side to receive a spirit lamp, and at the top to receive a teapot or tin boiler. The *infusion mug* of Mr. Alsop of London (see *Infusa*), which consists of a queensware vessel, with a perforated diaphragm of the same material resting on a ledge at one-third of its height from the top, is the best instrument for this purpose. The material to be infused is placed on the diaphragm and the boiling water poured on till it rises over the ingredients. No stirring is necessary, and the process is accomplished rapidly. Infusions and decoctions may be kept during the hot weather, and for many months by straining them *while hot*, and pouring them at once into bottles provided with accurately ground stoppers. The bottle must be entirely filled; the stopper being made to displace its own bulk of the liquid. A common bottle with a perforated cork stopper may be used, provided the hole be instantly closed, and the cork covered with sealing wax. The hotter the liquid and the freer from air bubbles, the better will the infusion be preserved.

Neutral mixture is known to be saturated perfectly, when it does not affect litmus paper either in its blue state, or when reddened by an acid. For preparing the effervescing draught it is advisable to keep in the shop a solution of carbonate of potassa containing an ounce to the pint. The silica which this salt contains precipitates after a few weeks, and leaves a perfectly clear solution; whereas that prepared at the time it is to be used always becomes turbid after being saturated. The carbonic acid, extricated in the preparation of the neutral mixture, combines at first, without effervescence, with the remaining carbonate, and forms a bisalt. This circumstance may lead, unless the solution be tested, to the supposition that the mixture is saturated.

In preparing extemporaneous mixtures by direction of the physician, it is of the first importance to mix the ingredients in the manner best calculated to insure a smooth and readily miscible compound, without any grittiness or imperfectly comminuted portions, when a part of the constituents are insoluble. Kino and

extract of rhatany should be first dissolved in boiling water, when admissible. If an aromatic water is directed, they should be rubbed to powder, mixed with the insoluble ingredients, if any, and the water gradually added, the whole being triturated till smoothly mixed. Emulsions of the gum-resins should be rubbed till all the particles are softened, and then strained, if any extraneous matter is present. Water can be saturated with camphor by means of carbonate of magnesia, and an aqueous mixture of any strength may be made with it, by triturating the camphor with magnesia, and shaking the mixture before using it. Camphor softens the gum-resins, and solid fats and oils, and may be rendered permanently miscible with water, in considerable quantity, by trituration with a fifth part of myrrh. In preparing oily emulsions in which gum Arabic, or gum and sugar are the medium, a sufficient quantity of water must be added (generally about twice their weight) to convert them into a thick mucilage before adding the oil, which must then be thoroughly mixed with the mucilage, and the remaining water added gradually with great care. Ether is rendered more soluble in water by trituration with spermaceti. The mixture should be filtered to separate the superfluous spermaceti. If elaterium is to be incorporated in a mixture, it should be first rubbed with a little alcohol, then with sugar or syrup, and lastly with the other ingredients. When a few drops of croton oil are to be suspended in a mixture, the latter will be more permanent if a little olive oil be added with the croton oil to increase its quantity. Mixtures that contain the resinous tinctures, should also contain syrup, with which the tincture should be first mixed, and the water then added very gradually. If a mixture contains laudanum and a fixed oil, the former should be first mixed with the syrup, and the oil afterwards incorporated, and lastly the water. The mixture will not otherwise be uniform. When a considerable quantity of sugar is added to a mixture it is best to use syrup, employing a fluidrachm of syrup for each drachm of sugar, and making allowance for the water contained in the syrup, which equals half its bulk.

Powders are often mixed together with difficulty, by means of a pestle and mortar, on account of their differing greatly in weight, or of their softness and compressibility, as charcoal and magnesia, or rhubarb and magnesia. In these cases the mixing should be completed with a spatula on a sheet of paper. In dividing powders into doses it is very desirable to fold the packages neatly and of a uniform size. The powder folder represented in the figure is very useful for this purpose. It may be made of mahogany or other hard wood. Instruments of this kind with a movable cheek, so as to be widened or contracted by a screw, and made of brass, are used in some of the shops. When volatile or deliquescent substances, as camphor and carbonate of potassa, are prescribed in several powders, these should be enveloped separately in tin foil or waxed paper; and when the number of doses is more than two they should be enclosed in a paper box.



In ordering pills care must be taken to avoid the use of deliquescent salts, and to deprive those which are efflorescent of their water of crystallization. The mass must be thoroughly incorporated previously to being divided; and this is particularly important when extracts of different degrees of hardness enter into the composition. A section of the mass should be throughout of uniform colour and consistency. Pills are to be rolled and preserved in powdered liquorice root, which ought to be kept for use in a tin box with a perforated lid, like a pepper box. When pills are of too soft a consistence, a little liquorice powder may be incorporated with them to render them more firm. Pills, into the composition of which gum Arabic enters, should be softened with syrup, and not with water,

as the latter renders the mass difficult to roll. For further remarks relative to the formation of masses for pills, see *Pilulæ*.

The proper cleanliness of his vessels is an object of great importance to the apothecary. Open vessels, as mortars and measures, are easily cleansed, and should be wiped dry immediately after being washed. Fats and resins are readily removed by pearlash, or tow and damp ashes, or sand; red precipitate and other metallic substances by a little nitric or muriatic acid; Prussian blue by means of pearlash. Bottles may be cleansed from the depositions which accumulate on their sides and bottom from long use in the shop, by a few shreds of grocers' paper, and a little clean water. They are to be shaken so as to give the paper and water a centrifugal motion, which effectually removes the dirt from the sides. They may be freed from oil by a little strong nitric acid, after the action of which water will thoroughly cleanse them. Long sticks armed with sponge, or dry linen or cotton cloth, should be provided for wiping dry the interior of flasks and bottles.* A wire bent at the end into a sort of hook will be found useful for getting corks out of bottles. Wire instruments with three prongs are made specially for this purpose. In the absence of these, a loop of twine will often be found a convenient means of effecting the same object. When the glass stopper of a bottle is fast, it may often be loosened by gently tapping its sides alternately with the handle of a spatula. Sometimes a drop or two of oil, alcohol, or water, will soften the cementing substance. It will sometimes answer to wrap the stopper in a cloth, insert it in a crevice or hole, in a table or door, and twist the bottle gently and dextrously. Sometimes the stopper may be loosened by quickly expanding the neck in the flame of a lamp, and tapping the stopper before the heat has reached it. The bottle should be constantly turned in the hand during the heating process, to avoid unequal expansion and fracture. In the absence of a flame, a piece of twine turned twice around the neck and drawn back and forward rapidly will soon heat it sufficiently, in most instances. When the stopper of a bottle containing caustic alkali adheres in consequence of the neck not having been wiped thoroughly dry, it is almost impossible to loosen it, and the neck must be cut off.

The apothecary should be provided with spatulas of wood, whalebone, and horn, as well as of steel. It should be an invariable rule to clean every knife and graduated measure immediately after it is used, and to put the dirty mortars apart from those which are clean. Too much particularity and order in all the minute details of the shop cannot be practised. The counters should be cleaned every day, and wiped as often as they become dusty. The scales should be thoroughly cleaned every week, and wiped always after using them for dusty substances; and the prescription *balance* should be kept carefully enclosed in a glass case, and the dishes wiped after each time of using. The beam should occasionally be wiped with a soft cotton or silk cloth. The mortar stand should pass through the floor and cellar, into the ground, so as not to jar the counter during the contusion of substances, and thus injure the balance. Bottles should be replaced as soon after being taken down and used as possible, and should on no account be changed from their accustomed place on the shelf. For the proper preservation of leaves, flowers, aromatic powders, calomel, and other medicines to which light is injurious, the bottles should be coated with tin foil or black varnish.

No apothecary should be unprovided with a set of *troy weights*, as without them

* The odour of volatile oils, and other strong smelling substances, such as musk, may be removed from bottles, mortars, &c., by means of the pulp of bitter almonds or peach kernels, bruised peach leaves, or other substances containing hydrocyanic acid. But fatty matters should first be removed by an alkaline solution, and resins by alcohol. (*Journ. de Chim. Méd.*, 1845, p. 535.) It is asserted that the powder of black mustard has the same effect. (*Ibid.*, 2*e sér.*, iii. 727.)

he will find it difficult to comply with the officinal directions for the preparation of his medicines; and the drawer in which his smaller weights are kept should be clean and free from dust, so that the weights may be accurate. In dispensing medicines, no vial or parcel should be suffered to leave the shop without its appropriate label, and this, in the case of prescriptions, should always be the physician's direction as to the manner of taking it, and not the name of the medicine, unless it be so directed by him. The prescription, or a copy of it, should be retained and numbered, and the same number marked on the parcel or bottle. Everything connected with the shop, and the dispensing and putting up of medicines and parcels, should be characterized by *neatness*, *accuracy*, *system*, and *competent knowledge*.

The apprentice who desires to qualify himself for his business, should carefully study Turner's, Graham's, or Fownes' Elements of Chemistry, Mohr and Redwood's Practical Pharmacy, and Faraday's Treatise on Chemical Manipulation, which may be termed the hand-books of his profession. D. B. S.

General Officinal Directions.

As all the processes of the United States and British Pharmacopœias are either described or fully detailed in the following pages, it is proper that the prefatory explanations of the several Pharmacopœias should be introduced in this place, in order that the reader may be prepared to understand the precise signification of the terms employed.

The Pharmacopœias recognised in this work, excepting that of the Dublin College, unite in the use of the *troy* or *apothecaries'* pound, and its divisions of ounces, drachms, scruples, and grains, for the expression of weights. Upon this subject the United States Pharmacopœia has the following note, to which the attention of apothecaries is particularly invited. "It is highly important that those engaged in preparing or dispensing medicines should be provided with *Troy* weights of all denominations; but, when these are not to be had, the same end may be attained by calculating the Avoirdupois pound at 7000 Troy grains, and the Avoirdupois ounce at 437·5 grains, and making the requisite allowance. Thus 42·5 grains added to the Avoirdupois ounce will make it equal to the Troy ounce, and 1240 grains deducted from the Avoirdupois pound will reduce it to the Troy pound." As the common weights of the country are the avoirdupois weights, and every apothecary is in possession of the lower denominations of the apothecaries' weight, viz. grains, scruples, and drachms, there can be no difficulty in complying with the officinal directions. The Dublin College, in the last edition of their Pharmacopœia, have abandoned the troy weights, and substituted the avoirdupois pound and ounce, in common use, but make a new division of the ounce into drachms and scruples, which are different in value from any denomination of weight hitherto used. Thus their ounce is divided into eight drachms of 54·68 grains each, and the drachm into three scruples of 18·22 grains each. The difference in value of these weights from others of the same denomination, and the fractions of grains contained in them, are likely to lead to much confusion and inconvenience.

Both in the *United States* and *British* Pharmacopœias, the quantity of fluids is generally indicated by the liquid measure, consisting of the gallon and its divisions of pints, fluidounces, fluidrachms, and minims. It is highly necessary that the apothecary should understand that this distinction is rigidly observed in all the details which follow, and that whenever the simple terms pound, ounce, and drachm are employed, they must be considered as belonging to the denomination of troy weight. This caution is the more necessary, as these terms are often confounded with the corresponding divisions of liquid measure, viz. the pint,

fluidounce, and fluidrachm. (See tables of weights and measures in the Appendix.)

All the British Colleges have adopted the Imperial gallon and its divisions instead of the wine gallon which they before employed. In the United States Pharmacopœia the wine gallon is still retained. This discrepancy is very unfortunate, as no one denomination of the imperial measure corresponds exactly with the same denomination of the wine measure; and the formulæ, therefore, of the British Colleges, so far as measures are concerned, when they agree in terms with those of the United States Pharmacopœia, differ from them in reality; while in other cases, though differing in terms, they may be quite or very nearly identical. It is very important that the apothecary should bear this distinction in mind; and, when he has occasion to carry into effect one of the foreign formulæ, that he should make the due allowances. He will find, among the Tables in the Appendix of this work, a statement of the relative value of the several denominations of the Imperial and wine measures, and by consulting this statement will be enabled to convert the former into the latter without difficulty. The measures kept in the shop should be graduated according to the divisions of the wine gallon; as this is recognised by our own officinal standard.

In the *Pharmacopœia of the United States*, and in that of the *Edinburgh College*, when the specific gravity of a body is given, it is considered to be at the temperature of 60°, of Fahrenheit; in the *London Pharmacopœia*, at 62°.

The *United States* and *London Pharmacopœias* explain the term *gentle heat* as signifying a temperature between 90° and 100°. Fahrenheit's scale is referred to by all the officinal standards.

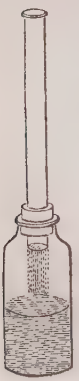
The *London College* directs that, when not otherwise ordered, glass, porcelain, or stoneware vessels shall be used for preparing and preserving medicines, at the same time guarding especially against the employment of earthen vessels glazed with lead. The same College also directs that acid, alkaline, and metallic preparations, and salts of every kind, be kept in stopped glass bottles, which, for certain substances, should be of black or green glass.

Whenever, in the *United States* and *London Pharmacopœias*, an acid or an alkali is directed to be saturated, the point of saturation is to be ascertained by means of litmus or turmeric. For this purpose litmus or turmeric paper is usually employed, the latter being rendered brown by the alkalies, the former being reddened by the acids, and having its blue colour restored by the alkalies. (See *Lacmus* and *Curcuma*.) The *London College* provides that, when the solution of carbonate of soda is employed to saturate an acid, all the carbonic acid be driven off by heat, before the test is applied. It directs, moreover, that in making experiments no other water than the distilled should be used; and that, unless otherwise ordered, white bibulous paper should be employed both for filtering liquids and drying crystals.

The *London College* uses Hessian or Cornish crucibles exclusively. It defines a *water bath* to be an arrangement by which anything, contained in its own vessel, is exposed either to hot water itself, or to the vapour of boiling water; and a *sand bath*, as consisting of sand to be gradually heated, in which anything, contained in its own vessel, is placed.

Percolation, or *Filtration by Displacement.* In relation to this process, the following directions are given in the *United States Pharmacopœia*. "The kind of filtration commonly designated as the *process of displacement*, which is employed in many of the processes of this Pharmacopœia, is to be effected in the following manner, unless otherwise specially directed. A hollow cylindrical instrument, called a *Percolator*, is to be used, somewhat conical towards the inferior extremity, having a funnel-shaped termination so as to admit of being inserted into the mouth of a bottle, and provided internally, near the lower end,

with a transverse partition or diaphragm, pierced with numerous minute holes, or, in the absence of such a partition, obstructed with some insoluble and inert substance, in such a manner that a liquid poured into the cylinder may percolate slowly. [See *page* 782.] The substance to be acted upon, having been reduced to a coarse powder, and mixed with enough of the menstruum to moisten it thoroughly, is, after a maceration of some hours, to be introduced into the instrument, and slightly compressed upon the diaphragm. Any portion of the macerating liquid which may not have been absorbed by the powder, is afterwards to be poured upon the mass in the instrument, and allowed to percolate. Sufficient of the menstruum is then to be gradually added to drive before it, or displace, the liquid contained in the mass; the portion introduced is in like manner to be displaced by another portion; and so on till the required quantity of filtered liquor is obtained. If the liquor which first passes should be turbid, it is to be again introduced into the instrument. Care must be taken that the powder be not, on the one hand, too coarse or loosely pressed, lest it should allow the liquid to pass too quickly, nor, on the other, too fine or compact, lest it should offer an unnecessary resistance. Should the liquor flow too rapidly, it is to be returned to the instrument, which is then to be closed beneath for a time, in order that the finer parts of the powder may subside, and thus cause a slower percolation."



The *Edinburgh College* gives directions for percolation under the head of Tinctures. According to that College, "the solid materials, usually in coarse or moderately fine powder, are moistened with a sufficiency of the solvent to form a thick pulp; in twelve hours, or frequently without any delay, the mass is put into a cylinder of glass, porcelain, or tinned iron, open at both ends, but obstructed at the lower end by a piece of calico or linen, tied tightly over it as a filter (*see figure in the margin*); and the pulp being packed by pressure, varying as to degree with various articles, the remainder of the solvent is poured into the upper part of the cylinder, and allowed gradually to percolate. In order to obtain the portion of the fluid which is kept in the residuum, an additional quantity of the solvent is poured into the cylinder, until the tincture which has passed through, equals in amount the spirit originally prescribed."

The advantages of the process of percolation or displacement are, that the active soluble principles of medicinal substances are in general extracted by it more speedily, thoroughly, and economically than by any other mode; that concentrated solutions of these principles are more easily obtained; and that no portion of the impregnated menstruum need be lost by remaining in the solid mass. It is, however, liable to the objection, that considerable experience and skill are necessary to carry it properly into effect, and that, if improperly performed, it must often result in preparations very different from those contemplated in the formulæ. It should not, therefore, be resorted to in the fulfilment of officinal directions, when any alternative is given, unless by individuals who have acquired the requisite skill by much practice. Hence, both the United States and Edinburgh Pharmacopœias, when directing displacement in any particular case, frequently give another mode of accomplishing the same object, better adapted to inexperience in the operator.

The sources of failure in this process are chiefly an improper degree of comminution in the substance to be acted upon, and an improper condition of the mass after it has been introduced into the instrument. If the material be in too fine a powder, it resists or obstructs the passage of the fluid; if too coarse, it allows the fluid to pass too rapidly, and at the same time opposes its cohesion to the solvent power of the menstruum. If merely bruised, especially if fibrous pieces of some length are intermixed, it causes the fluid to make irregular chan-

nels, and thus to act upon it partially. An improper packing of the material occasions similar inconveniences. If too compact it impedes, if too loose it injuriously facilitates the passage of the solvent, and if not uniform, it produces an irregular flow which necessarily vitiates the result. The liquid, finding an easier passage at one part than another, flows more rapidly in that direction, and thus makes channels by which it may in great measure or wholly escape, with little influence upon the mass. Besides, the uniform progression by which each superadded portion displaces that immediately beneath it is broken, the successive layers become intermingled, and thus one of the peculiar advantages of the process is lost. The following observations may be of some use in assisting the operator to avoid these consequences.

The solid material should in general be in the state of a uniform coarse powder, to which it is most conveniently brought by grinding in a common coffee-mill. If its texture, however, be very hard, firm, and not easily permeable by moisture, as in certain barks, woods, and ligneous roots, it should be rather finely powdered. If, on the contrary, the texture be loose and spongy, and especially if the material be disposed to swell up and form a viscid mass with water, so as to impede percolation, as in the case of gentian and squill, it may be advisable merely to bruise it in a mortar; though care should be taken to do this as equably as possible; and the substances which require this treatment when water is used, may come under the general rule with another solvent, as alcohol or ether.

It is generally advisable, before introducing the material into the instrument, to mix it with a portion of the solvent, and allow it to stand for some time in another vessel. It thus becomes more penetrable and more easily acted on by the menstruum, admits of a more uniform packing, and, if liable to swell with water, undergoes this expansion where it cannot have the effect of checking percolation. The quantity of liquid should be sufficient to form a soft pulp-like mass with the powder. In general, a weight about half that of the solid material will be sufficient, though a much larger quantity may be used, if on any account deemed advisable. The maceration may continue on the average about twelve hours; but a much shorter time will often answer. It has sometimes been recommended to perform this preliminary maceration in the displacement filter, its lower orifice being closed for a time. With some substances this may be done without disadvantage; but in all those instances in which the material is liable to swell considerably with water, and thus to choke the passage, the maceration should take place in another vessel.

The packing of the material in the instrument is that part of the process which most requires experience in the operator, and about which the least precise rules can be given. When mixed with a considerable portion of fluid, it will often subside of itself into the proper state; but generally it requires some shaking or pressure, and the degree of the latter must be in proportion to the looseness of texture in the material; reference, however, being always had to its disposition to swell with water. Certain substances in which this property is found, such as gentian and rhubarb, must not be pressed compactly, when water is the solvent. As the percolation advances, and portions of the substance acted on are dissolved, the mass often becomes too loose, and requires to be again pressed down. Substances which are apt to form with the menstruum an adhesive and impermeable mass, such as the resins and gum-resins, may be advantageously mixed, in the state of coarse powder, with about half their weight of perfectly clean white sand, as suggested by the late Mr. Duhamel. (See *Am. Journ. of Pharm.*, x. 15.) The sand separates the particles of the mass, and allows the menstruum a readier access.

After the moistened material has been properly packed, the upper surface

should be made quite level, and then covered with a circular disk of tin or filtering paper pierced with numerous minute holes; and, if the disk be of paper, it should be kept in its place by pieces of glass rod. The solvent is thus made to enter into the mass equably, and prevented from forming partial passages by bearing upon one or a few points. The liquid is now to be introduced in successive portions, as stated in the officinal directions above given, and in the general account of the process given at page 782.

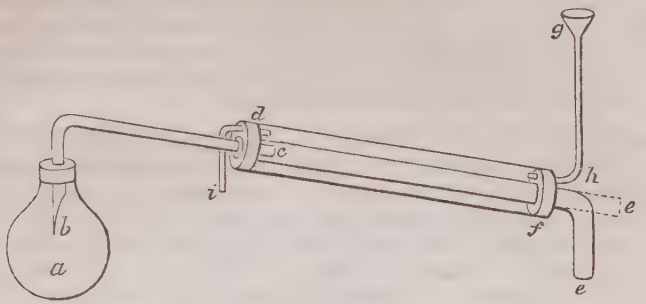
The fluid which first passes is turbid, unless the diaphragm has been covered by a close filtering material. Should it be turbid, it should be returned into the instrument, before the addition of any displacing menstruum; and the same thing should continue to be done, until the liquid comes away perfectly clear. If the percolation be too rapid, pressure may be made upon the upper diaphragm so as to render the mass more compact, or the instrument may be closed below for a time, as stated in the officinal direction. Hence the advantage of having a stop-cock near the lower end for regulating the discharge. In the absence of a stop-cock, a soft cork may be used, with a small groove cut lengthwise for a short distance from its smaller end. By withdrawing the cork until the groove appears, a passage for the fluid can be opened at will. When the percolation is too slow, it may be increased by the pressure of a column of liquid, and this plan may sometimes be advantageously resorted to when the powder is very fine, or large masses of material are operated upon. (See *page* 783.) When the object is to keep up a constant supply of the percolating fluid, it may be accomplished by filling a long-necked bottle or matrass with the fluid, and inverting it over the filtering instrument, with its mouth beneath the surface of the liquid in the latter.

Hot liquids may be used in the process as well as cold, and are sometimes preferable when the substance yields its active principles more largely at an elevated temperature. But there is often an inconvenience in employing hot water; as it dissolves or renders glutinous substances not affected by cold water, which are not requisite, and may even be injurious in the preparation, and which tend to embarrass the process by filling up the interstices of the mass, and thus rendering it less permeable. An instrument has been invented by Mr. C. A. Smith, of Cincinnati, by which the menstruum is made to enter the contents of the percolator in the state of hot vapour, and, being condensed by means of a refrigerating vessel surrounding the percolator, passes out in the liquid form, highly impregnated with the soluble principles of the material operated on. (See *Am. Journ. of Pharm.*, xviii. 98.)

The first portion of filtered liquid is very strongly impregnated, and the portions which subsequently come away, are successively less so. It is sometimes desirable to obtain the whole of the particular solvent employed. This end may be very nearly attained by adding, at the close of the process, enough of another liquid to supply the place of that retained in the mass. It was Boullay's idea that the whole of the liquid contained in the moist material might be thus driven out of it or displaced by the one added, without any admixture of the two. This, however, has been ascertained not to be exactly true; and, however carefully the process may be conducted, some mixture will take place. Hence, it is recommended, when one liquid is added in order to displace another, to introduce first a shallow layer of the same liquid with that contained in the mass. In some instances, the solvent, if consisting of two liquids, is resolved into these in the process. Thus, when myrrh is subjected to percolation with proof spirit, the first liquid which comes away is alcohol holding the oil and resin of the myrrh in solution.

There are very few substances to which the mode of filtration by displacement will not be found applicable, if due attention be paid to the circumstances which require variations in the process.

Distillation. In the preface to the last edition of the *Edinburgh Pharmacopœia*, the following remarks are made in relation to this process. "In the process of distillation, complete success cannot be easily attained, especially on



the small scale, without the substitution of a different apparatus for the retort and receiver commonly used. In all operations, except where inorganic acids are to be distilled, it is greatly preferable to use a globular matrass (*a*), to which is fitted with a cork a tube (*bc*), cut obliquely at its lower end (*b*), curved above at a somewhat acute angle, and fitted at the other end to a refrigeratory. This refrigeratory consists of a long narrow cylinder (*df*) slightly inclined to the horizon, and of a tube (*ce*) which passes along the centre of the cylinder, and is fixed at each end, so that the space between them is air-tight; and by means of a funnel (*gh*) entering at the lower end of this interspace, and an exit tube (*di*) from its upper extremity, a stream of cold water may be kept constantly running, by which refrigeration and the condensation of vapours within the inner tube are far more effectually accomplished than by any other mode that has hitherto been devised." This is *Liebig's distillatory apparatus.* The object of the oblique ending of the tube at *b*, is to prevent any of the fluid which may be driven against it, during the ebullition, from passing along the tube. The inner tube of the refrigeratory should be made of glass or block-tin, the outer may consist of glass, brass, copper, or common tinned iron. The end *e* of the central tube is either straight, or curved downward so that it may be inserted into a bottle, when the liquid distilled is very volatile. By connecting the funnel with a cistern by means of a syphon, and allowing the water to flow out from the bent tube *di* into a bucket or sink, the distillation may be allowed to go on for a long time without supervision. Dr. Christison states that a refrigeratory, with the outer tube a foot long, and an inch and a quarter in diameter, will be sufficient to condense the whole vapour from a matrass holding two pints of alcohol briskly boiling. W.

ACETA.

Vinegars.

Under this title, in the United States Pharmacopœia, are included both Distilled Vinegar and those preparations usually denominated *Medicated Vinegars.* The latter are infusions or solutions of various medicinal substances in vinegar or acetic acid. The advantage of vinegar as a menstruum is that, in consequence of the acetic acid which it contains, it will dissolve substances not readily soluble, or altogether insoluble, in water alone. It is an excellent solvent of the organic alkalies, which it converts into acetates, thereby modifying, in some measure, though not injuriously, the action of the medicines of which they are ingredients. As ordinary vinegar contains principles which promote its decomposition, it should be purified by distillation before being used as a solvent. In-

fusions prepared with it, even in this state, are apt to spoil in a short time; and a portion of alcohol is usually added to contribute to their preservation. A small quantity of acetic ether is said to result from this addition; and, on the continent of Europe, the place of the alcohol is frequently supplied by an equal amount of concentrated acetic acid. At present diluted acetic acid is generally preferred as the menstruum to distilled vinegar, as being of more uniform strength. In consequence of their liability to change, the medicated vinegars should be made in small quantities, and kept but for a short time. W.

ACETUM DESTILLATUM. *U.S.*, *Lond.*, *Ed.* *Distilled Vinegar.*

"Take of Vinegar *a gallon*. Distil the Vinegar, by means of a sand-bath, from a glass retort into a glass receiver. Discontinue the process when seven pints shall have been distilled, and keep these for use." *U. S.*

The *London* process is the same as that of the U. S. Pharmacopœia. The *Edinburgh* process is as follows. "Take of Vinegar (French by preference) *eight parts:* distil over with a gentle heat, *seven parts:* dilute the product, if necessary, with distilled water till the density is 1·005."

Vinegar is a very heterogeneous liquid, containing colouring matter, gum, sugar, alcohol, &c.; and the object of its distillation is to purify it. (See *Acetum.*) The first portion which distils contains alcohol and pyroacetic spirit (acetone), these being the most volatile ingredients; next the acetic acid comes over much purified, but weaker than it exists in the vinegar, on account of its being less volatile than water; and, if the distillation be stopped when the pure vinegar ceases to come over, there will be found in the retort a liquid of a deep-brown colour, very sour and empyreumatic, and containing free tartartic and malic acids, bitartrate of potassa, and other substances. This statement explains why the last portion (one-eighth) is not distilled; the seven-eighths which first come over being alone preserved. The residuary liquid in the retort, if diluted with an equal bulk of hot water, may be made to yield, by a fresh distillation, a quantity of weak acetic acid equal to the residuary liquid, and of about the strength and purity of officinal distilled vinegar.

Wine vinegar furnishes a stronger and more aromatic distilled vinegar than malt or cider vinegar. The London College gives 1·0065 as the density of distilled vinegar. The Edinburgh College, assuming that distilled vinegar will have the sp. gr. of at least 1·005, directs that its density, when above that number, shall be reduced to it. The U. S. Pharmacopœia does not give the density, on account of its being an uncertain criterion of strength. The saturating power is the proper test of the acid present. This is given in the different Pharmacopœias as follows. A fluidounce is saturated by about 35 grains of crystallized bicarbonate of potassa (*U. S.*); an Imperial fluidounce by 57 grains of crystallized carbonate of soda (*Lond.*); and 100 minims by 8 grains of the same carbonate (*Ed.*) The saturating power, thus given, of the different officinal distilled vinegars indicates the following proportions of monohydrated acetic acid per cent., assuming the sp. gr. of the U. S. distilled vinegar to be 1·005;—*U. S.* Pharmacopœia 4·5, *London* 5·4, *Edinburgh* 3·6. Considering the ordinary pharmaceutical uses of distilled vinegar, variations in its strength, limited as they are by the qualities of different vinegars, are not very important. Its purity is the point of importance. If, however, precision be attempted, the saturating power and not the density must be indicated; and directions should be given for bringing a distilled vinegar, which varies from the standard of saturating power, to that standard by the addition either of pure acetic acid, or of distilled water. The reason why density cannot be depended upon, is that the specific gravity is not in proportion to the strength. If the vinegar contain a good deal of alcohol and pyroacetic spirit, the distilled product will be light, but not necessarily weak. This remark applies particularly to distilled wine vinegar.

The U. S. Pharmacopœia directs the distillation of vinegar to be conducted in glass vessels; but it is generally distilled in a copper alembic furnished with a pewter worm. The use of these metals, however, is hazardous, on account of the danger of metallic impregnation. Mr. Brande has suggested that the condenser might be made of very thin silver, a metal not acted on by acetic acid of any strength. If this cannot be procured, the head and worm should be of glass or earthenware. Empyreuma is effectually prevented by distilling by means of steam.

Properties. Distilled vinegar is a limpid, colourless liquid, of a weak acetous taste and smell, less agreeable than those of common vinegar. It is wholly volatilized by heat. It is not a perfectly pure solution of acetic acid in water; but contains a portion of organic matter which rises in the distillation. It is on account of the partial decomposition of this impurity that distilled vinegar, when saturated with an alkali, is liable to become of a reddish or brownish colour. When distilled in metallic vessels, it is apt to contain traces of copper, lead, and tin. Copper is detected, after saturating with ammonia, by the addition of ferrocyanuret of potassium, which produces a brown cloud; lead by iodide of potassium, which occasions a yellow precipitate; and tin by a solution of chloride of gold, which causes a purplish appearance. The two latter metals are discovered also by sulphuretted hydrogen, which occasions a dark-coloured precipitate. The non-action of this gas proves the absence of metals generally. Distilled vinegar should have neither an empyreumatic taste nor a sulphurous smell. As usually prepared, however, it is somewhat empyreumatic. British malt vinegar is allowed by law to contain one-thousandth of sulphuric acid; but, when it is distilled, this acid does not come over. If, however, sulphuric acid should be accidentally present in distilled vinegar, it may be detected by chloride of barium or acetate of lead. If muriatic acid be present, it may be shown by a precipitate being formed with nitrate of silver; and if nitric acid be an impurity, the vinegar will possess the property, by digestion, of dissolving silver, which may be detected afterwards by muriatic acid.

Medical Properties and Uses. The medical properties of distilled vinegar are the same as those of common vinegar (see *Acetum*); but the former, being purer, and not liable to spontaneous decomposition, is preferable for pharmaceutical purposes. Still, it is less pure than the officinal diluted acetic acid, which has been substituted for it in a number of preparations.

Off. Prep. Acetum Colchici; Acetum Opii; Acetum Scillæ; Ammoniæ Acetatis Aqua; Emplastrum Ammoniaci. B.

ACETUM CANTHARIDIS. (*Epispasticum.*) *Lond.* ACETUM CANTHARIDIS. *Ed., Dub. Vinegar of Spanish Flies.*

"Take of Spanish Flies, in very fine powder, *two ounces;* Acetic Acid *a pint* [Imperial measure]. Macerate the Spanish Flies with the acid for eight days, occasionally shaking. Finally express and filter." *Lond.*

"Take of Cantharides, in powder, *three ounces;* Acetic Acid *five fluidounces;* Pyroligneous Acid *fifteen fluidounces;* Euphorbium, in coarse powder, *half an ounce.* Mix the acids, add the powders, macerate for seven days, strain and express strongly, and filter the liquor." *Ed.*

"Take of Spanish Flies, in fine powder, *four ounces;* Strong Acetic Acid *four fluidounces;* Acetic Acid of Commerce (sp. gr. 1·044) *sixteen fluidounces.* Mix the Acids, and, having added the Flies, macerate in a close vessel for fourteen days; then strain through flannel with expression, and filter so as to obtain a clear liquor." *Dub.*

This preparation is intended exclusively for external use, as a speedy epispastic. It is said, when lightly applied by a brush, to act as a rubefacient; and, when rubbed freely upon the skin for three minutes, to be followed, in two or

three hours, by full vesication. The pain produced by the application, though more severe, is also more transient than that occasioned by the blistering cerate. From experiments made by Mr. Redwood, it may be inferred that the preparation proves epispastic chiefly if not exclusively in consequence of its acetic acid, and that it contains little of the active principle of the flies. (*Lond. Pharm. Journ. and Trans.*, Oct. 1841.) Prof. Procter finds that, by digestion at a temperature of 212° F., the active principle of the flies is readily taken up by officinal acetic acid, though a portion of the cantharidin is deposited upon cooling. (*Am. Journ. of Pharm.* xxiv. 299.) It would seem, therefore, that the vinegar of Spanish flies would be best prepared with the aid of heat. W.

ACETUM COLCHICI. *U. S., Lond., Ed., Dub. Vinegar of Colchicum.*

"Take of [dried] Colchicum Root, bruised, *two ounces;* Diluted Acetic Acid *two pints.* Macerate the Colchicum Root with the Diluted Acetic Acid, in a close glass vessel, for seven days; then express the liquor, and set it by that the dregs may subside; lastly, pour off the clear liquor.

"Vinegar of Colchicum may also be prepared by macerating the Colchicum Root, in coarse powder, with a pint of Diluted Acetic Acid for two days, then putting the mixture into a percolator, and gradually pouring upon it Diluted Acetic Acid until the quantity of filtered liquor equals two pints.

"In the above processes, Distilled Vinegar may be substituted for Diluted Acetic Acid." *U. S.*

"Take of dried Colchicum Cormus *three drachms and a half;* Diluted Acetic Acid *a pint* [Imperial measure]; Proof Spirit *a fluidounce and a half.* Macerate the Colchicum with the Acid in a covered vessel for three days; then express, and set apart that the dregs may subside; lastly, add the spirit to the filtered liquor." *Lond.*

"Take of Colchicum-bulb, fresh and sliced, *one ounce;* Distilled Vinegar *sixteen fluidounces;* Proof Spirit *one fluidounce.* Macerate the Colchicum in the Vinegar for three days in a covered glass vessel; strain and express strongly; filter the liquors, and add the spirit." *Ed.*

"Take of Colchicum Bulbs, dried and bruised, *one ounce;* Acetic Acid of Commerce (sp. gr. 1·044) *four fluidounces;* Distilled Water *twelve ounces* [*fluidounces*]. In the Acid, diluted with the Water, macerate the Colchicum, in a close vessel for seven days; then strain with expression, and filter." *Dub.*

Of these processes the American and Dublin yield the strongest preparation, and on this account are preferable. They also agree in omitting the spirit, which, in the London and Edinburgh processes, is intended to retard the spontaneous decomposition to which this, like the other medicated vinegars, is liable, but is of little use.

Vinegar is an excellent solvent of the active principle of colchicum; and the organic alkali of the latter loses none of its efficacy by combination with the acetic acid of the former.

Medical Uses. This preparation has been extolled as a diuretic in dropsy, and may be given in gout, rheumatism, and neuralgia; but the wines of colchicum are usually preferred. It is recommended by Scudamore to be given in connexion with magnesia, so as to neutralize the acetic acid of the menstruum. The dose is from thirty drops to two fluidrachms. W.

ACETUM OPII. *U. S., Ed., Dub. Vinegar of Opium. Black Drop.*

"Take of Opium, in coarse powder, *eight ounces;* Nutmeg, in coarse powder, *an ounce and a half;* Saffron *half an ounce;* Sugar *twelve ounces;* Diluted Acetic Acid *a sufficient quantity.* Digest the Opium, Nutmeg, and Saffron with a pint and a half of the Diluted Acetic Acid, on a sand-bath, with a gentle heat,

for forty-eight hours, and strain. Digest the residue with an equal quantity of the Diluted Acetic Acid, in the same manner, for twenty-four hours. Then put the whole into a percolator, and return the filtered liquor, as it passes, until it comes away quite clear. When the filtration has ceased, pour Diluted Acetic Acid gradually upon the materials remaining in the instrument, until the whole quantity of filtered liquor equals three pints. Lastly, add the Sugar, and, by means of a water bath, evaporate to three pints and four fluidounces.

"In the above process, Distilled Vinegar may be substituted for Diluted Acetic Acid." *U. S.*

"Take of Opium *four ounces;* Distilled Vinegar *sixteen fluidounces.* Cut the Opium into small fragments, triturate it into a pulp with a little of the Vinegar, add the rest of the Vinegar, macerate in a closed vessel for seven days, and agitate occasionally. Then strain and express strongly, and filter the liquor." *Ed.*

"Take of Opium, in coarse powder, *one ounce and a half;* Dilute Acetic Acid *one pint* [Imperial measure]. Macerate for seven days in a close vessel, with occasional agitation; then strain with expression, and filter." *Dub.*

The vinegar of opium has been introduced into the Pharmacopœias as an imitation of or substitute for a preparation, which has been long in use under the name of *Lancaster* or *Quaker's black drop*, or simply *black drop.* The formula of the first edition of the U. S. Pharmacopœia was so deficient in precision, and so uncertain in its results, that it was abandoned in the second edition; but, as this objection was obviated in a process by Mr. Charles Ellis, published in the *American Journal of Pharmacy* (vol. ii. page 202), and as the preparation continued to enjoy a considerable degree of professional and popular favour, it was deemed proper to restore it to its officinal rank at the subsequent revision of the Pharmacopœia. The U. S. formula above given is essentially that of Mr. Ellis. It is, we think, preferable to the Edinburgh and Dublin formulæ. In the former of these we cannot but suspect that there is some waste of opium, as it is the same as the old Dublin formula; and Dr. Montgomery, in his observations on the former Dublin Pharmacopœia, states that twenty drops of the preparation are equivalent to thirty of the common tincture of opium, though, in making the latter, somewhat less than one-third the quantity of opium is used. In the present Dublin process, much less opium is employed, and the resulting vinegar, is probably of about the same strength as laudanum. In the last U. S. formula, diluted acetic acid has been substituted for distilled vinegar. The advantages of the black drop over laudanum are, probably, that disturbing principles contained in opium and soluble in alcohol are left behind by the aqueous menstruum employed; while the meconate of morphia is converted by the acetic acid into the acetate. In the original process, published by Dr. Armstrong, who found it among the papers of a relative of the proprietor in England, *verjuice*, or the juice of the wild crab, was employed instead of vinegar. Other vegetable acids also favourably modify the narcotic operation of opium; and lemon juice has been employed in a similar manner with vinegar or verjuice, and perhaps not less advantageously.*

* The following is the formula given in the first edition of the U. S. Pharmacopœia. "Take of Opium *half a pound;* Vinegar *three pints;* Nutmeg, bruised, *one ounce and a half;* Saffron *half an ounce.* Boil them to a proper consistence; then add Sugar *four ounces;* Yeast *one fluidounce.* Digest for seven weeks, then place in the open air until it becomes a syrup; lastly, decant, filter, and bottle it up, adding a little sugar to each bottle." The boiling to a *proper consistence*, the digestion in the open air *until a syrup is formed*, and the addition of a *little sugar* to each bottle, are all indefinite directions which must have led to uncertain results. Independently of this want of precision, the point in which the old process chiefly differs from that at present officinal is, that, in the former, fermentation is induced by the addition of yeast. But fermentation is of very doubtful value in the process; at least its advantages have not been proved.

The vinegar of opium may sometimes be advantageously used when opium itself, or the tincture, in consequence of peculiarity in the disease or in the constitution of the patient, occasions so much headache, nausea, or nervous disorder, as to render its employment inconvenient if not impossible. It exhibits all the anodyne and soporific properties of the narcotic, with less tendency to produce these disagreeable effects, at least in many instances. The U. S. preparation is of about double the strength of laudanum, six and a half minims containing the soluble parts of about one grain of opium, supposing the drug to be completely exhausted by the menstruum. The dose may be stated at from seven to ten drops or minims. W.

ACETUM SCILLÆ. *U. S., Lond., Ed., Dub. Vinegar of Squill.*

"Take of Squill, bruised, *four ounces;* Diluted Acetic Acid *two pints.* Macerate the Squill with the Diluted Acetic Acid, in a close glass vessel, for seven days; then express the liquor, and set it by that the dregs may subside; lastly, pour off the clear liquor.

"Vinegar of Squill may also be prepared by macerating the Squill, in coarse powder, with a pint of Diluted Acetic Acid for two days, then putting the mixture into a percolator, and gradually pouring upon it Diluted Acetic Acid until the quantity of filtered liquor equals two pints.

"In the above processes, Distilled Vinegar may be substituted for Diluted Acetic Acid." *U. S.*

The *London College* directs *two ounces and a half* of recently dried squill, *a pint* (Imperial measure) of diluted acetic acid, *a fluidounce and a half* of proof spirit, and maceration with a gentle heat for three days. The *Edinburgh College* directs *five ounces* of dried squill, *two pints* (Imp. meas.) of distilled vinegar, *three fluidounces* of proof spirit, and maceration for seven days. The *Dublin College* takes *two ounces* of dried squill, *four fluidounces* of acetic acid of commerce (sp. gr. 1·044), and *twelve fluidounces* of distilled water; and macerates for seven days.

In the United States process by percolation, the whole of the diluted acid employed in the maceration, and introduced with the squill into the instrument, should be allowed to enter the mass, before the fresh portion is added. The preparations of the several Pharmacopœias are so nearly the same that, for all practical purposes, they may be considered identical. In the present U. S. and Dublin processes the alcohol has been omitted. Its only object is to retard the decomposition of the vinegar of squill; while its presence is medically injurious by rendering the preparation too stimulating. It is best, therefore, to prepare the vinegar of squill frequently, and in small quantities, so as not to require alcohol for its preservation. In the preparation of the oxymel and syrup of squill, for which purpose the vinegar is chiefly used in this country, it should be employed without alcohol. The vinegar of squill deposits, upon standing, a precipitate which consists, according to Vogel, of citrate of lime and tannic acid.

Medical Uses. This preparation has all the properties of the squill in substance, and is occasionally prescribed as a diuretic and expectorant in various forms of dropsy and of pulmonary disease; but the oxymel and syrup are usually preferred, as they keep better, and are less unpleasant to the taste. The dose is from thirty minims to two fluidrachms; but the latter quantity would be apt to produce vomiting. It should be given in cinnamon water, mint water, or some other aromatic liquid calculated to conceal its taste and obviate nausea.

Off. Prep. Oxymel Scillæ; Syrupus Scillæ. W.

ACIDUM ACETICUM CAMPHORATUM. *Ed., Dub. Camphorated Acetic Acid.*

"Take of Camphor *one ounce* [half an ounce, *Ed.*]; Rectified Spirit *one fluidrachm;* Strong Acetic Acid *ten fluidounces* [Acetic Acid six fluidounces and

a half, *Ed.*]. Reduce the camphor to powder by means of the spirit; then add the Acid, and dissolve." *Dub., Ed.*

The use of the alcohol is simply to facilitate the pulverization of the camphor, and a few drops are sufficient. Acetic acid in its concentrated state readily dissolves camphor. In this preparation, the whole of the camphor is taken up by the acid. In consequence of the powerful chemical agency of the solution, and its extreme volatility, it should be kept in glass bottles accurately fitted with ground stoppers.

Camphorated acetic acid is an exceedingly pungent perfume, which, when snuffed up the nostrils, produces a strongly excitant impression, and may be beneficially resorted to in cases of fainting or nervous debility. It is an officinal substitute for Henry's *aromatic spirit of vinegar.*

At Apothecaries' Hall, in London, an *aromatic vinegar* is prepared by dissolving the oils of cloves, lavender, rosemary, and calamus, in highly concentrated acetic acid. It is used for the same purpose as the officinal camphorated acetic acid, being dropped on sponge and kept in smelling bottles. A similar preparation may be made extemporaneously by adding to a drachm of acetate of potassa, contained in a stoppered bottle, three drops of one or more of the aromatic volatile oils, and twenty drops of sulphuric acid. (*Pereira's Mat. Med.*)

A preparation called *Marseilles vinegar*, or *thieves' vinegar* (*vinaigre des quatres voleurs*), consisting essentially of vinegar impregnated with aromatic substances, was formerly esteemed a prophylactic against the plague and other contagious diseases. It is said to have derived its name and reputation from the circumstance, that four thieves, who, during the plague at Marseilles, had plundered the dead bodies with impunity, confessed, upon the condition of a pardon, that they owed their safety to the use of it. The *aromatic acetic acid* of the former Edinburgh Pharmacopœia was intended as a simplification of this nostrum. It was made by macerating for a week an ounce of rosemary, an ounce of sage, half an ounce of lavender, and half a drachm of cloves, with two pounds of distilled vinegar, then expressing the liquor and filtering. Origanum was afterwards substituted for sage, and thirty fluidounces of acetic acid for the two pounds of distilled vinegar. In the last edition of the Pharmacopœia the preparation was abandoned. In the present state of knowledge, it is hardly necessary to observe that neither the original nostrum, nor its substitute, has any other power of protecting the system against disease than such as may depend on its slightly stimulant properties, and its influence over the imagination. W.

ACIDA.

Acids.

Acids, in chemical classification, are compounds which are capable of uniting in definite proportions with alkalies, earths, and ordinary metallic oxides, with the effect of producing a combination, in which the properties of its constituents are mutually destroyed. Such combinations are said to be neutral, and are denominated salts. Most acids have a sour taste, and possess the power of changing vegetable blues to red; and, though these properties are by no means constant, yet they afford a ready means of detecting acids, applicable in practice to most cases. The above explanation of the nature of an acid is that usually given; but, according to strict definition, acids are compounds having a strong electro-negative energy, and, therefore, possessing a powerful affinity for electro-positive compounds, such as alkalies, earths, and ordinary oxides. It is this antagonism in the electrical condition of these two great classes of chemical compounds that gives rise to their mutual affinity, which is so much the stronger as the contrast

in this respect is greater. In the majority of cases, the electro-negative compound or acid is an oxidized body, but by no means necessarily so. When an acid does not contain oxygen, hydrogen is usually present. These peculiarities in composition have given rise to the division of acids by some writers into *oxacids* and *hydracids*. *Vegetable acids*, for the most part, contain both hydrogen and oxygen.

The number of acids used in medicine is small; but among these are to be found examples of the three kinds above mentioned. B.

ACIDUM ACETICUM DILUTUM. *U. S.*, *Lond.*, *Dub.* *Diluted Acetic Acid.*

"Take of Acetic Acid [sp. gr. 1·041] *a pint;* Distilled Water *seven pints.* Mix them." *U. S.* The sp. gr. of this acid is 1·004, and 100 grains of it saturate 7·5 grains of crystallized bicarbonate of potassa.

"Take of Acetic Acid [sp. gr. 1·048] *twenty-three fluidrachms* [Imp. meas.], Distilled Water *a pint* [Imp. meas.]. To the Acid add enough of the Water to fill accurately the measure of a *pint* [Imp. meas.], and mix." *Lond.* The sp. gr. of this acid is 1·008, and an Imperial fluidounce of it is saturated by 57 grains of crystallized carbonate of soda.

"Take of Acetic Acid of Commerce (sp. gr. 1·044) *one pint;* Distilled Water *seven pints.* Mix." *Dub.* The sp. gr. of this acid is 1·006.

The object of having this preparation is to possess a weak solution of pure acetic acid, which may be substituted for distilled vinegar in all formulæ in which nicety is required. Distilled vinegar contains a portion of organic matter, which is always darkened or precipitated when this acid is saturated with an alkali, an occurrence which does not take place when the diluted acetic acid is employed. The saturating strength of the diluted acids of the U. S. and London Pharmacopœias indicates the same per centage of monohydrated acetic acid as is contained in the corresponding distilled vinegars; namely, 4·5 *U. S.*, and 5·4 *London*. The *Dublin* diluted acid, being intermediate in density, may be assumed to be intermediate in strength. While the London distilled vinegar and diluted acid have precisely the same saturating strength, the former is lighter than the latter in the proportion of 1·0065 to 1·008. This arises from the fact that the acetic acid in distilled vinegar is in part diluted with alcohol and pyroacetic spirit, which are lighter than water.

The acetic acid diluted in making this preparation, is known in commerce as "No. 8." In all cases in which the apothecary is doubtful as to its being of the officinal strength, it will be his duty to ascertain its saturating power, and, if this should vary from the standard, to vary the dilution accordingly.

Off. Prep. Acetum Colchici; Acetum Opii; Acetum Scillæ; Emplastrum Ammoniaci; Extractum Colchici Aceticum; Liquor Ammoniæ Acetatis; Syrupus Allii; Unguentum Plumbi Compositum. B.

ACIDUM BENZOICUM. *U. S.*, *Lond.*, *Ed.*, *Dub.* *Benzoic Acid.*

"Take of Benzoin, in coarse powder, *a pound.* Put the Benzoin into a suitable vessel, and, by means of a sand-bath, with a gradually increasing heat, sublime until vapours cease to rise. Free the sublimed matter from oil by pressure in bibulous paper, and again sublime." *U. S.*

The *London College* has transferred benzoic acid to the Materia Medica list, directing, however, that it shall be prepared by sublimation. The *Edinburgh College* puts a convenient quantity of benzoin into a glass matrass, and operates in the manner directed in the U. S. Pharmacopœia.

"Take of Benzoin *any convenient quantity.* Place it in a small cylindric pot of sheet iron, furnished with a flange at its mouth; and having fitted the pot into a circular hole in a sheet of pasteboard, interpose between the pasteboard and

flange a collar of tow, so as to produce a nearly air-tight junction. Let a cylinder of stiff paper, open at one end, eighteen inches high, and having a diameter at least twice that of the pot, be now placed in an inverted position on the pasteboard, and secured to it by slips of paper and flour paste. A couple of inches of the lower part of the pot being passed through a hole in a plate of sheet tin, which is to be kept from contact with the pasteboard by the interposition of a few corks, let a heat just sufficient to melt the benzoin (that of a gas-lamp answers well) be applied, and continued for at least six hours. Let the product thus obtained, if not quite white, be enveloped in bibulous paper, then subjected to powerful pressure, and again sublimed." *Dub.*

The Pharmacopœias now unite in procuring benzoic acid by sublimation. In the former U. S. process, the benzoin was mixed with an equal weight of sand; but this was omitted in the last edition of the Pharmacopœia, as not only useless, but probably injurious by favouring the production of empyreumatic substances. The acid, which exists in the benzoin combined with resin, is volatilized by the heat, and condensed in the upper part of the apparatus. Unless the temperature is very carefully regulated, a portion of the resin is decomposed, and an oily substance generated, which rises with the acid and gives it a brown colour, from which it cannot be entirely freed by bibulous paper; and this result sometimes takes place even with the greatest caution. The process for subliming benzoic acid may be conducted in a glazed earthen vessel, surmounted by a cone of paper, or by another vessel with a small opening at top, and a band of paper pasted round the place of junction. After the heat has been applied for an hour, the process should be suspended till the condensed acid is removed from the upper vessel or paper cone, when it may be renewed, and the acid again removed, and thus alternately till coloured vapours rise. Mohr, after many experiments, recommends the following plan as unobjectionable. In a round cast-iron vessel, eight or nine inches in diameter and two inches deep, a pound or less of coarsely powdered benzoin is placed, and uniformly strewed over the bottom. The top of the vessel is closed by a sheet of bibulous paper, which is secured to the sides by paste. A cylinder of thick paper in the form of a hat, just large enough to fit closely around the sides of the pot, is then placed over it, and in like manner secured by paste. A moderate heat is now applied by means of a sand-bath, and continued for three or four hours. The vapours pass through the bibulous paper, which absorbs the empyreumatic oil, and are condensed within the hat in brilliant white flowers, having an agreeable odour of benzoin. (*Annal. der Pharm.*, xxix. 178.) The remaining acid of the benzoin may be extracted, if deemed advisable, by treating the residue of the balsam with lime or carbonate of soda. From the mode of preparing benzoic acid by sublimation, it was formerly called *flowers of benzoin.*

Another mode of separating the acid from benzoin is by combining it with a salifiable base, and precipitating with an acid. Such is the process of Scheele. It consists in boiling the powdered benzoin with hydrate of lime and water, filtering the solution of benzoate of lime thus obtained, and precipitating the benzoic acid with muriatic acid. Carbonate of soda or of potassa may be substituted for the lime, and sulphuric for the muriatic acid; and the precipitated benzoic acid may be purified by dissolving it in boiling water, which will deposit it upon cooling. Stenhouse unites the process of Scheele with one proposed by Liebig. After concentrating the solution of benzoate of lime, procured by boiling equal parts of benzoin and hydrate of lime with water, he adds a strong solution of chloride of lime, and subsequently a slight excess of muriatic acid, and boils till the chlorine is dissipated. The bleaching effect of the chlorine on the crystals of benzoic acid is thus obtained. The acid, however, requires to be still further purified by repeated crystallization from small portions of boiling water.

A little animal charcoal may be employed to render the crystals quite colourless. These processes afford a purer product than that obtained by sublimation, but not preferable in a medicinal point of view; as the small quantity of oil present in the sublimed acid adds to its stimulant properties, and at the same time renders it pleasant to the smell.

Several other modes of extracting the acid have been recommended. The following is the process of Stolze. One part of the balsam is dissolved in three parts of alcohol, the solution filtered and introduced into a retort, and the acid saturated by carbonate of soda dissolved in a mixture of eight parts of water and three of alcohol. The alcohol is distilled off; and the benzoate of soda contained in the residuary liquid is decomposed by sulphuric acid, which precipitates the benzoic acid. This is purified by solution in boiling water, which lets fall the acid when it cools. By this process Stolze obtained 18 per cent. of acid from benzoin containing 19·425 per cent. By the process of Scheele he obtained 13·5 per cent.; by the agency of carbonate of soda, 12 per cent.; by sublimation only 7·6 per cent. Nevertheless, Mr. Brande says that the last process is on the whole the most economical. According to this author, good benzoin affords by sublimation from 10 to 15 per cent. of the acid contaminated with empyreumatic oil, and about 9 per cent. of the purified acid. Professor Scharling has prepared benzoic acid by means of heated steam, and obtained 8 per cent. (*Am. Journ. of Pharm.*, xxiv. 236.)

Properties. Sublimed benzoic acid is in white, soft, feathery crystals, of a silky lustre, and not pulverulent. From solution the acid crystallizes in transparent prisms. When quite pure it is inodorous; but, prepared by sublimation from the balsam, it has a peculiar agreeable aromatic odour, dependent on the presence of an oil, which may be separated by dissolving the acid in alcohol, and precipitating it with water. Its taste is warm, acrid, and acidulous. It is unalterable in the air, but at 230° melts, and at a somewhat higher temperature rises in suffocating vapours. It is inflammable, burning without residue. It is soluble in 200 parts of cold water (*Annals of Pharmacy*, i. 206), and in about twenty-four parts of boiling water, which deposits it upon cooling. It is soluble in alcohol, and in concentrated sulphuric and nitric acids, from which it is precipitated by water. The fixed oils also dissolve it. It is entirely dissolved by solutions of potassa, soda, ammonia, and lime, from which it is precipitated by muriatic acid. Its solution reddens litmus paper, and it forms salts with salifiable bases; but its acid properties are not powerful. Benzoic acid consists of *benzyle* and oxygen, and in the uncombined state usually contains water. The anhydrous acid has, however, been isolated by Gerhardt. (*Chem. Gaz.* x. 237.) Benzyle consists of fourteen eqs. of carbon 84, five of hydrogen 5, and two of oxygen 16=105. The crystallized acid contains one eq. of benzyle 105, one of oxygen 8, and one of water 9=122. It cannot be deprived of its water by heat, but sometimes loses it in combination. Benzoic acid is a characteristic constituent of the balsams, and has been found in various other vegetable, and some animal products.*

Medical Properties and Uses. Benzoic acid is irritant to the alimentary mucous membrane, and stimulant to the system, and has been thought to be expectorant; but it is seldom used internally except as a constituent of one or two officinal preparations. It was proposed by Dr. Alexander Ure as a remedy for uric acid deposits in the urine, and for the chalk-like concretions, consisting of

* *Benzyle*, which was at first hypothetical, has been isolated. When benzoate of copper is cautiously distilled without water, it yields a product which crystallizes on cooling. This substance has the smell of geranium, melts at 158° F., and has a composition represented by the formula $C_{14}H_5O_2$. When heated with hydrate of potassa, it is converted into benzoic acid, with the escape of hydrogen. It is, therefore, benzyle. It was discovered by Ettling, and afterwards investigated by Stenhouse. (*Fowne's Chemistry*, Am. Ed., 1853, p. 401.)

urate of soda, in the joints of gouty individuals. He supposed it to operate by converting the uric into hippuric acid, and consequently the insoluble urates into soluble hippurates. It appears, however, from the observations of Dr. Garrod and Mr. Keller, that such a transformation of uric acid does not take place, but that the benzoic acid is itself converted into hippuric acid, which is always found in the urine, when the former acid is taken freely. The quantity of uric acid in the urine remains undiminished. In consequence of the acid state of urine produced by benzoic acid, it has been found useful in the phosphatic variety of gravel; though its beneficial influence, being purely chemical, continues only during its use. (*Journ. de Pharm.*, 3e *sér.*, ii. 327, iii. 41, iv. 397.) It is said to have cured nocturnal incontinence of urine. Mr. White Cooper has employed it with supposed advantage in a case of rheumatic sclerotitis. (See *Am. Journ. of Med. Sci.*, N. S., xxv. 518.) A convenient mode of exhibition is to give the acid with four parts of phosphate of soda, or one part and a half of biborate of soda, which enable it to be readily dissolved by water. The dose is from 10 to 30 grains. It is an ingredient in some cosmetic washes, and has been employed by way of fumigation as a remedy in affections of the skin.

ACIDUM GALLICUM. *U. S.*, *Lond.*, *Dub.* *Gallic Acid.*

"Take of Galls, in powder, *three pounds;* Distilled Water, Animal Charcoal, each, a *sufficient quantity*. Mix the Galls with sufficient Distilled Water to form a thin paste, and expose the mixture to the air, in a shallow glass or porcelain vessel, in a warm place, for a month, occasionally stirring it with a glass rod, and adding from time to time sufficient Distilled Water to preserve the semi-fluid consistence. Then submit the paste to expression, and, rejecting the expressed liquor, boil the residue in a gallon of Distilled Water for a few minutes, and filter while hot through Animal Charcoal. Set the hot liquor aside that crystals may form, which may be dried on bibulous paper. If the crystals be not sufficiently free from colour, they may be purified by dissolving them in boiling Distilled Water, filtering through a fresh portion of Animal Charcoal, and crystallizing." *U. S.*

The *London College* places Gallic Acid in its Materia Medica catalogue, directing simply that it be in crystals, and prepared from galls.

The *Dublin College* gives two processes, of which the first is essentially the same as that of the U. S. Pharmacopœia. It differs in requiring an exposure of six weeks instead of a month, in not expressing the paste before boiling in water, and in expressing the impure acid deposited from the filtered decoction, before redissolving it in boiling water. The second process is as follows.

"Take of powdered Galls *one pound* [avoirdupois]; Oil of Vitriol of Commerce *twenty-six fluidounces;* Water *five pints* [Imp. meas.] and *fourteen* [*fluid*] *ounces*. Steep the galls for twenty-four hours in one part of the water, then transfer them to a glass or porcelain percolator, and pour on a pint and a half of the water in successive portions. Dilute five ounces of the oil of vitriol with an equal bulk of water, and, when the mixture has cooled, add it to the infusion obtained by percolation, stirring well, so as to bring them into perfect contact. Let the viscid precipitate which forms be separated by a filter, and to the solution which passes through add five ounces more of the oil of vitriol, which will yield an additional precipitate. This being added to that previously obtained, let both be enveloped in calico, and subjected to powerful pressure. Dissolve the residue in the rest of the oil of vitriol, this latter being first diluted with what remains of the water; boil the solution for twenty minutes, then allow it to cool, and set it by for a week. Let the deposit which has formed at the end of this period be pressed, dried, and then dissolved in three times its weight of

boiling water, clearing the solution, if necessary, by filtration, and, when it has cooled down to 80°, decant the liquid from the crystalline sediment which has formed, and wash the latter with three ounces of ice-cold water. Finally, let it be transferred to blotting paper, and when deprived by this of adhering liquid, let it be dried perfectly at a temperature not exceeding 212°. The gallic acid obtained may be rendered nearly white by dissolving it in twenty times its weight of boiling distilled water, and causing the solution to traverse a stratum of prepared animal charcoal spread upon a calico filter. When the liquid passes through colourless it should be evaporated to one-sixth of its volume, and then suffered to cool in order to the separation of the crystallized acid." *Dub.*

The U. S. process is founded upon the fact that, when galls in decoction or in the state of moistened powder, are exposed to the air, their tannic acid is gradually converted into gallic acid, with the absorption, as generally believed, of oxygen, and the escape of an equivalent quantity of carbonic acid. The gallic acid, being freely soluble in boiling but very sparingly in cold water, is extracted from the altered galls by decoction, and is deposited as the water cools. A repetition of the solution and deposition renders the acid more pure; but it cannot be obtained wholly free from colour unless by the aid of animal charcoal. In the U. S. Pharmacopœia it was neglected, no doubt through inadvertence, to direct *purified* animal charcoal. There are few processes in which it is more necessary that this decolorizing agent should be purified. The presence of the slightest quantity of sesquioxide of iron interferes with the bleaching of the acid; and it is even advisable to examine the filtering paper employed, lest it may contain sufficient of this substance to vitiate the results of the process. The first crop of crystals in the U. S. process retains a very large proportion of water; and it will be found convenient to subject them to strong expression between folds of bibulous paper.

Dr. C. Wetherill, believing that gallic acid differs from the tannic simply in containing water, conceived the idea of preparing the former from the latter by the fixation of water. This he effected through the agency of sulphuric acid. Having mixed 13 drachms of tannic acid with 22 fluidounces of sulphuric acid and four times that bulk of water, he heated the mixture to the boiling point, and then allowed it to stand. In a few days an abundant precipitate of white gallic acid took place, amounting to 87·4 per cent. of the tannic acid. (See *Am. Journ. of Pharm.*, xx. 112.) Upon the same principle is based the second process of the Dublin College. Dr. Christison, in his Dispensatory, states that the process was originally suggested by Liebig.

Some new and interesting views have been advanced in relation to the formation of gallic acid from the tannin of galls. The elder Robiquet first suggested that galls contain a principle capable of converting tannic into gallic acid, with the presence of water, and in the absence of atmospheric air. M. Larocque proved that this principle acts as a ferment, and that the change referred to is the result of a *gallic acid fermentation* in the galls. M. Edmund Robiquet has shown that galls contain *pectose* and *pectase*, the former of which, according to the experiments of M. Fremy, is the principle out of which pectin is formed in plants, and the latter a peculiar ferment which effects the transformation. It appears that in galls the pectase, aided by a proper temperature and the presence of water, changes not only pectase into pectin, but also tannic into gallic acid. Strecker had previously advanced the opinion that tannic acid is a combination of gallic acid and sugar, the latter of which is destroyed in the process for procuring gallic acid, which is thus simply set free from the combination. It would seem, if this view is correct, that the pectase acts upon the saccharine matter of the tannic acid, causing its conversion into carbonic acid and alcohol, and liberating the gallic acid, and that the process is in fact an example of the vinous fermentation. M. E. Robiquet admits the occasional transformation of tannic

acid into gallic acid and sugar, but does not believe that the sugar pre-exists as such in the tannin; and this point yet remains to be determined. (*Journ. de Pharm.*, 3e *ser.*, xxiii. 241.) Wittstein, in endeavouring to obtain gallic acid from *Chinese galls* (see *page* 357) by forming them into a paste with water, found that but a very small proportion of the acid was generated at the end of six weeks. Thinking that this might have resulted from the want of the ferment in the Chinese galls, he added to these one-eighth of their weight of common galls, and at the end of three weeks obtained an amount of gallic acid nearly equal to one-half the weight of the galls employed. The same result, though more slowly, followed the addition of yeast to the Chinese galls. Wittstein obtained both carbonic acid and alcohol as products of this operation, thus favouring the views of Strecker as to the constitution of tannic acid. (See *Am. Journ. of Pharm.*, xxv. 258.)

Properties. Gallic acid is in delicate, silky, acicular crystals, which, as ordinarily found in the shops, are slightly brownish, but when quite pure are colourless. It is inodorous, and of a sourish astringent taste. It is soluble, according to Braconnot, in 100 parts of cold and 3 of boiling water, is very soluble in alcohol, and but slightly so in ether. It reddens litmus, and produces a deep bluish-black colour with solutions of the salts of the sesquioxide of iron, which disappears when the solution is heated. It does not precipitate gelatin, or a solution of sulphate of protoxide of iron. On exposure to the air, its solution undergoes spontaneous decomposition. The formula of gallic acid is $C_7H_3O_5$, and its combining number 85. Heated to 420° it gives out carbonic acid, and is converted into *pyrogallic acid.** Thrown on red-hot iron it is entirely dissipated.

Medical Properties. Forming an ingredient in all astringent products containing gallo-tannic acid, it was at one time supposed to be the active principle of the vegetable astringents. This reputation it afterwards lost when the properties of tannic acid became well known. But it has recently again come into notice, and is now thought by many to be a very valuable astringent, having the property of arresting hemorrhages when taken internally, especially those from the uterus and urinary passages. In all cases of hemorrhage in which the bleeding vessels must be reached through the route of the circulation, it is believed by some to be more efficient even than tannic acid, as its chemical affinities do not afford the same impediment to its absorption as those of the latter acid. But in hemorrhage from the alimentary mucous membrane or from any other part with which tannic acid can be brought into direct contact, this astringent is by far the most effectual. Gallic acid is said not to constipate the bowels. The dose is from five to fifteen grains three or four times a day, and may be given in the form of pill or powder. W.

ACIDUM HYDROCYANICUM DILUTUM. *U. S.*, *Lond.*, *Dub.* Acidum Hydrocyanicum. *Ed. Diluted Hydrocyanic Acid. Prussic Acid. Cyanohydric Acid.*

"Take of Ferrocyanuret of Potassium *two ounces;* Sulphuric acid *an ounce and a half;* Distilled Water *a sufficient quantity.* Mix the acid with four fluid-ounces of Distilled Water, and pour the mixture, when cool, into a glass retort. To this add the Ferrocyanuret of Potassium, previously dissolved in ten fluid-

* In consequence of the great sensitiveness of *pyrogallic acid* to light, in connexion with certain metallic salts, it has come into use as an agent in *photography.* According to Löwig, it is best prepared by heating gallic acid, previously dried at 212° F., in a glass retort, by means of a chloride of zinc bath, to 410° F., when pure pyrogallic acid sublimes. It is white, foliated, inodorous, very bitter, soluble in three and a half parts of water, readily dissolved by alcohol and ether, fusible at 239° F., and sublimable at 410° F., in irritating vapours. Chlorine, iodine, and acids which readily yield oxygen decompose it instantaneously.—*Note to the tenth edition.*

ounces of Distilled Water. Pour eight fluidounces of Distilled Water into a cooled receiver, and, having attached this to the retort, distil, by means of a sand-bath, with a moderate heat, six fluidounces. Lastly, add to the product five fluidounces of Distilled Water, or as much as may be sufficient to render the Diluted Hydrocyanic Acid of such strength, that 12·7 grains of nitrate of silver, dissolved in distilled water, may be accurately saturated by 100 grains of the Acid.

"Diluted Hydrocyanic acid may also be prepared, when wanted for immediate use, in the following manner.

"Take of Cyanuret of Silver *fifty grains and a half;* Muriatic Acid *forty-one grains;* Distilled Water *a fluidounce.* Mix the Muriatic Acid with the Distilled Water, add the Cyanuret of Silver, and shake the whole in a well-stopped vial. When the insoluble matter has subsided, pour off the clear liquor and keep it for use. Diluted Hydrocyanic Acid should be kept in closely stopped bottles from which the light is excluded." *U. S.*

The process of the *London College* for diluted hydrocyanic acid is the same as that of the U. S. Pharmacopœia; the latter having been adopted from the former. The following is the *Edinburgh* formula, Imperial measure being used.

"Take of Ferrocyanide of Potassium *three ounces;* Sulphuric Acid *two fluidounces;* Water *sixteen fluidounces.* Dissolve the salt in eleven fluidounces of the Water, and put the solution in a matrass with a little sand: add the Acid, previously diluted with five fluidounces of the Water and allowed to cool: connect the matrass with a proper refrigeratory: distil with a gentle heat, by means of a sand-bath or naked gas-flame, till fourteen fluidounces pass over, or till the residuum begins to froth up. Dilute the product with distilled water till it measures sixteen fluidounces." *Ed.*

The *Dublin College,* in its Pharmacopœia of 1850, has abandoned the employment of cyanuret of mercury and muriatic acid as the source of this acid, and adopted the use of ferrocyanuret of potassium and sulphuric acid, in imitation of the other British Pharmacopœias. The process adopted is virtually the same as those just given, and, therefore, need not be quoted.

Hydrocyanic acid was admitted into the French Codex in 1818, into the United States Pharmacopœia in 1820, into the Dublin in 1826, into the London in 1836, and into the Edinburgh in 1839. It is now made by one chief process; namely, from the ferrocyanuret of potassium by the action of sulphuric acid. It is also obtained by an extemporaneous process, when wanted for immediate use, in the U. S. Pharmacopœia, by decomposing the cyanuret of silver. When ferrocyanuret of potassium is decomposed by sulphuric acid, the residue in the retort is bisulphate of potassa, mixed with a compound of two eqs. of cyanuret of iron and one of cyanuret of potassium (*Everitt's salt*). Two eqs. of ferrocyanuret $2(FeCy+2KCy)$, react with six eqs. of hydrated sulphuric acid $6(SO_3+HO)$, and produce three eqs. of hydrated bisulphate of potassa $3(KO,2SO_3+HO)$, together with one eq. of Everitt's salt $2FeCy+KCy$, which remain in the retort, and three eqs. of hydrocyanic acid $3HCy$, which distil over. Everitt's salt, so named from its discoverer, called *biferrocyanuret of potassium* by Dr. Pereira, is yellow according to Mr. Everitt; but Dr. Pereira, who prepared it with the greatest care, always found it white. Its constitution $(2FeCy+KCy)$ is precisely the converse of that of ferrocyanuret of potassium $(FeCy+2KCy)$.

According to Mr. Phillips, the proportion of sulphuric acid, directed by the Edinburgh College, is so large that there is great risk of the production of formic acid. (*Observations on the Ed. Pharm., &c.*) The acid, instead of exceeding the weight of the ferrocyanuret, should only form three-fourths of its weight. In relation to the most convenient method of bringing the hydrocyanic acid to the standard strength, and to some other points in its preparation by the officinal formula, the reader is referred to a paper by Prof. Procter, contained in the *Amer. Journ. of Pharmacy,* xix. 259.

The rationale of the U. S. process for obtaining hydrocyanic acid extemporaneously is exceedingly simple. The reacting materials are single equivalents respectively of cyanuret of silver and muriatic acid. These, by double decomposition, generate hydrocyanic acid which dissolves in the water, and chloride of silver which subsides, and from which the acid is poured off when clear. (See *Argenti Cyanuretum.*) The extemporaneous process is useful to country practitioners; because the acid will not generally keep. A portion of hydrocyanic acid, if procured by a practitioner, may spoil on his hands, before he has occasion to use it; but if he supplies himself with cyanuret of silver, he may readily at any moment prepare a small portion of the acid, by following the directions of the formula.

The French Codex of 1837 gives the following process for hydrocyanic acid, in place of the three formerly contained in that work. Take of bicyanuret of mercury thirty parts; muriatic acid (sp. gr. 1·17) twenty parts. Reduce the bicyanuret to powder, and introduce it into a small tubulated glass retort, placed over a furnace. Adapt to its neck a tube about 13 inches long, and half an inch in diameter, and filled one-half with pieces of marble, and the remainder with chloride of calcium. To this tube, arranged nearly horizontally, adapt a smaller one, bent at a right angle, and plunging into a graduated tube, surrounded with a mixture of common salt and pounded ice. The apparatus being thus arranged, and the junctures well luted, add the muriatic acid; and, having allowed the action to take place for a few moments in the cold, apply the heat gradually. When the action is over, drive forward any acid which may have condensed in the large tube, by means of a live coal brought near to it, and passed along its whole length. The quantity of acid found in the graduated tube is mixed with either six times its bulk, or eight and a half times its weight of distilled water.

The above process is Gay-Lussac's, and, therefore, the same in principle as the former Dublin. In the first part of it, Gay-Lussac's strong acid is obtained in the graduated tube, and this is afterwards diluted to a given extent with water. The object of the marble and chloride of calcium is to detain, the former muriatic acid, the latter water.

Another process for obtaining medicinal hydrocyanic acid, proposed by Dr. Clarke, and adopted by Mr. Laming, is by the reaction of tartaric acid on cyanuret of potassium in solution. Laming's formula is as follows. Dissolve twenty-two grains of the cyanuret in six fluidrachms of distilled water, and add fifty grains of crystallized tartaric acid, dissolved in three fluidrachms of rectified spirit. Crystallized bitartrate of potassa precipitates, and each fluidrachm of the clear decanted liquor contains one grain of pure hydrocyanic acid. The reaction in this process takes place between two eqs. of tartaric acid, one of cyanuret of potassium, and one of water. The water is decomposed, and the tartaric acid, potassium, and oxygen unite to form the bitartrate, and the cyanogen and hydrogen to form the hydrocyanic acid. Dr. Pereira considers this process to have several advantages, but very properly objects to it on account of the trouble and expense of obtaining the cyanuret of potassium pure, and its liability to undergo spontaneous decomposition. (See *Potassii Cyanuretum.*)

Liebig recommends the decomposition of cyanuret of potassium with hydrated sulphuric acid. In this case the products of the double decomposition are sulphate of potassa and hydrocyanic acid. Any cyanate of potassa present as an impurity is at the same time decomposed, and the ammonia resulting from the cyanic acid unites with the sulphuric acid, so as to form a supersulphate. The mode of proceeding is to distil one part of the cyanuret, dissolved in two parts of water, with one part of sulphuric acid, diluted with three parts of water. The hydrocyanic acid obtained is much stronger than the medicinal acid; but it may be reduced to any desired standard by the addition of the proper proportion of distilled water.

The processes, thus far given, are intended to furnish a *dilute* hydrocyanic acid for medicinal purposes. The methods of obtaining the *anhydrous* or pure acid are different. Vauquelin's process for the pure acid is to pass a current of hydrosulphuric acid gas over the bicyanuret of mercury contained in a glass tube, connected with a receiver kept cold by a freezing mixture of ice and salt. The first third only of the tube is filled with the bicyanuret; the remaining two-thirds being occupied, half with carbonate of lead, and half with chloride of calcium; the carbonate being intended to detain the hydrosulphuric acid gas, the chloride to separate water. Another process for the anhydrous acid is that of Gautier, the details of which are thus given by Berzelius. The ferrocyanuret of potassium is fused without access of air, whereby it is converted into a mixture of cyanuret of potassium and carburet of iron. The mass obtained, after having been pulverized and placed in a flask, is slightly moistened with water, and acted on with muriatic acid, added by small portions at a time. By a double decomposition between the cyanuret and muriatic acid, chloride of potassium and hydrocyanic acid are formed. The flask is then plunged into hot water, which causes the hydrocyanic acid to be disengaged in the form of vapour. This is passed through a tube containing chloride of calcium, and finally received in a small flask kept cool by a freezing mixture.

The process of Wöhler for the anhydrous acid is substantially the same as that of Liebig. The cyanuret of potassium selected is a black cyanuret, formed by fusing together 8 parts of dry ferrocyanuret, 3 of ignited cream of tartar, and 1 of charcoal in fine powder in a covered crucible. This is better than Liebig's cyanuret, which contains a large amount of cyanate of potassa. The cyanuret, while still warm, is exhausted by 6 parts of water, and the clear solution, placed in a retort, is decomposed by cold dilute sulphuric acid, gradually added. The hydrocyanic acid is condensed first in a U-shaped tube, containing chloride of calcium, and surrounded with ice-cold water, and afterwards in a small bottle, connected with the U-shaped condenser by a narrow tube, and immersed up to the neck in a mixture of ice and salt. After the acid has been condensed and dehydrated in the U-tube, the cold water surrounding it is withdrawn by a siphon, and replaced by water at a temperature between 85° and 90° Fahr., whereby the anhydrous acid is made to distil over into the small bottle.

Properties of the Medicinal Acid. Diluted hydrocyanic acid, of the proper medicinal strength, is a transparent, colourless, volatile liquid, possessing a taste at first cooling, afterwards somewhat irritating, and a peculiar smell. It imparts a slight and evanescent red colour to litmus. If it reddens litmus strongly and permanently, the fact shows the presence of some acid impurity. It is not reddened by the iodo-cyanuret of potassium and mercury. The non-action of this test shows the absence of contaminating acids, which, if present, would decompose the test, and give rise to the red iodide of mercury. It is liable to undergo decomposition if exposed to the light, but is easily kept if the bottle containing it is covered with black paint, or black paper. Its most usual impurities are sulphuric and muriatic acids; the former of which may be detected by chloride of barium, which will produce a precipitate of sulphate of baryta; and the latter, by precipitating with nitrate of silver, when so much of the precipitate as may be chloride of silver will be insoluble in boiling nitric acid, while the cyanuret of silver is readily soluble. The presence of these acids in slight amount is injurious, only in so far as they render the strength of the acid uncertain. Indeed, Mr. Barry, of London, adds a small proportion of muriatic acid to all his medicinal hydrocyanic acid, in order to preserve it. (*Pereira.*) But the presence of a mineral acid is not necessary for its preservation; for Dr. Christison has known medicinal hydrocyanic acid from ferrocyanuret of potassium to keep perfectly well, although nitrate of baryta, added to it, did not produce the slightest muddiness. If lead be present, it may be detected by hydrosulphuric

acid gas, which will cause a blackish precipitate. Hydrocyanic acid is incompatible in prescriptions with nitrate of silver, the salts of iron and copper, and most of the salts of mercury.

The medicinal acid is of different strengths, as ordered by the different pharmaceutical authorities. Formerly its strength was indicated by its specific gravity, which is lower in proportion as it is stronger; but this unprecise mode of estimate has been generally abandoned. The Pharmacopœias now, with the exception of the Dublin, rely on the saturating power as an index of strength. According to the *United States* formula, 100 grains of the acid must accurately saturate 12·7 (12.59, *Lond.*) grains of nitrate of silver, dissolved in distilled water, and produce a precipitate (cyanuret of silver), which, when washed and dried at a temperature not exceeding 212°, shall weigh 10 grains, and be wholly soluble in boiling nitric acid. An acid of this strength contains 2 per cent. of the pure anhydrous acid. The test of entire solubility in boiling nitric acid, applied to the precipitate obtained by nitrate of silver, is intended to verify its nature; for, if the hydrocyanic acid contain muriatic acid, part of this precipitate would be chloride of silver, not soluble in the boiling acid. The *Edinburgh* acid is directed to contain about 3·22 per cent. of anhydrous acid. The mode laid down by the College for testing its strength by nitrate of silver, admits of a variation in this particular; the stronger allowable acid being one-tenth stronger than the weaker. The *Dublin* acid is directed to have the sp. gr. 0·997, and probably contains a little over 2 per cent. of the anhydrous acid. Its saturating strength is not given. Scheele's medicinal hydrocyanic acid contains five per cent. of anhydrous acid; and, therefore, two minims of it are equal to five of the U. S. acid. The use of Scheele's acid should be discouraged as unnecessary, and as leading to mistakes.

MM. Fordos and Gélis have proposed as a test of the strength of the preparations containing cyanogen, an alcoholic solution of iodine of known strength; as, for example, three grains to the fluidounce. The test solution is added, drop by drop, to the cyanogen compound, until a permanent yellowish tinge is produced. The iodine unites with the cyanogen in the ratio of their equivalents; and hence the cyanogen present is easily calculated from the iodine expended. This test is commended for its accuracy by Mr. James Roberton, of Manchester. (See *Am. Journ. of Pharm.*, Nov. 1853, p. 551.)

Properties of the Anhydrous Acid. Hydrocyanic acid, perfectly free from water, is a colourless, transparent, inflammable liquid, of extreme volatility, boiling at 80°, and congealing at 5°. Its sp. gr. as a liquid is 0·6969, at the temperature of 64°; and as a vapour 0·9423. Its taste is at first cooling, then burning, with an after-taste in the throat like that of bitter almonds; but, from its extremely poisonous nature, it must be tasted with the utmost caution. Its odour is so strong as to produce immediate headache and giddiness; and its vapour so deleterious that it cannot be inhaled without the greatest danger. Both water and alcohol dissolve it readily. It is much more prone to undergo decomposition than the dilute acid. In the course of a few hours it sometimes begins to assume a reddish-brown colour, which becomes gradually deeper, till at length the acid is converted into a black liquid, which exhales a strong smell of ammonia. It is a very weak acid in its chemical relations, and reddens litmus but slightly. It does not form solid compounds with metallic oxides, but a cyanuret of the metal, the elements of water being exhaled. According to Sobero, hydrocyanic acid is generated, in sensible quantities, by the action of weak nitric acid on the volatile oils and resins. Though a product of art, it exists in some plants. It is, however, a matter of doubt, in many cases in which it is extracted from vegetables, whether it is an educt or a product. (See *Amygdala Amara.*)

Composition, &c. Hydrocyanic acid consists of one eq. of cyanogen 26, and one of hydrogen 1=27; or, in volumes, of one volume of cyanogen and one

volume of hydrogen without condensation. *Cyanogen* is a colourless gas, of a strong and penetrating smell, inflammable, and burning with a beautiful bluish-purple flame. Its sp. gr. is 1·8157. It was discovered in 1815 by Gay-Lussac, who considered it a compound radical, which, when acidified by hydrogen, becomes hydrocyanic acid. It consists of two eqs. of carbon 12, and one of nitrogen 14=26; or, in volumes, of two of carbon vapour, and one of nitrogen, condensed into one. The ultimate constituents of hydrocyanic acid are, therefore, two eqs. of carbon, one of nitrogen, and one of hydrogen.

Hydrocyanic acid, in a dilute state, was discovered in 1780 by Scheele, who correctly stated its constituents to be nitrogen, carbon, and hydrogen; but the peculiar way in which they are combined was first pointed out by Gay-Lussac, by whom also the anhydrous acid was first obtained.

Medical and Toxicological Properties. Hydrocyanic acid is one of the most deadly poisons known, proving, in many cases, almost instantaneously fatal. According to Dr. Christison, a grain and a half of the anhydrous acid is capable of producing death in the human subject. In the opinion of Dr. Meyer, it acts by paralysing the heart, being conveyed into the blood, and operating directly on that organ. One or two drops of the pure acid are sufficient to kill a vigorous dog in a few seconds. Notwithstanding its tremendous energy as a poison, it has been ventured upon in a dilute state as an anodyne and antispasmodic. Though occasionally resorted to as a remedy previously to 1817, yet it did not attract much attention until that year, when Magendie published his observations on its use in diseases of the chest, and recommended its employment to the profession. When given in medicinal doses gradually increased, it produces the following symptoms in different cases:—peculiar bitter taste; increased secretion of saliva; irritation in the throat; nausea; disordered respiration; pain in the head; giddiness; faintness; obscure vision; and tendency to sleep. The pulse is sometimes quickened, at other times reduced in frequency. Occasionally salivation and ulceration of the mouth are produced. It has been highly recommended and extensively used in complaints of the respiratory organs, and is supposed to exert a control over pulmonary inflammation, after the excitement has been diminished by bloodletting; and there is no doubt that, in some instances, it may be beneficial under such circumstances. Dr. Joseph Johnson, of Charleston, S. C., has found it useful in pneumonia. (*Charleston Med. Journ.*, Sept. 1853, p. 643.) In phthisis it may be resorted to with advantage as a palliative for the cough. In various other affections of the chest, attended with dyspnœa or cough, such as asthma, hooping-cough, and chronic catarrh, it has often been decidedly beneficial, by allaying irritation or relaxing spasm. In hypertrophy of the heart, and aneurism of the aorta, it has also been used with advantage. In various affections of the stomach, characterized by pain and spasm, and sometimes attended with vomiting, but unconnected with inflammation, it has proved beneficial in the hands of several practitioners. It has also been administered as an anodyne in several painful affections, as cancer, tic douloureux, &c., but with doubtful advantage. Sometimes it is used externally, diluted with water, as a wash in cutaneous diseases. The late Dr. A. T. Thomson, from personal observation, insisted particularly on its efficacy in allaying the itching in impetiginous affections.

The dose of the medicinal hydrocyanic acid of the U. S. Pharmacopœia, is from two to six drops, dissolved in distilled water, or mixed with gum water or syrup. It requires to be administered with the greatest caution, on account of the minuteness of the dose, and the great variableness in strength of the acid as found in the shops. The proper plan, therefore, is to begin with a small dose, two drops, for example, and gradually to increase the quantity until some obvious impression is produced. If giddiness, weight at the top of the head, sense of tightness at the stomach, or faintness come on, its use should be discontinued.

In all cases in which a fresh portion of medicine is used, the dose should be lowered to the minimum quantity, lest the new sample should prove stronger than that previously employed. When resorted to as a lotion, from thirty minims to a fluidrachm may be dissolved in a fluidounce of distilled water.

Hydrocyanic acid is so rapidly fatal as a poison that physicians have seldom an opportunity to treat its effects. When not immediately fatal, the symptoms produced are sudden loss of sense, trismus, difficult and rattling respiration, coldness of the extremities, smell of the acid proceeding from the mouth, though this is sometimes absent, smallness of the pulse, swelling of the neck, dilatation, immobility, and sometimes contraction of the pupils, convulsions, &c. The antidotes and remedies most to be relied on, are chlorine, ammonia, cold affusion, and artificial respiration. Chlorine in the form of chlorine water, or weak solutions of chlorinated lime or soda, may be exhibited internally, or applied externally. When chlorine is not at hand, water of ammonia, largely diluted, may be given, and the vapour arising from it cautiously inhaled. A case is related in the *Dublin Med. Journal*, for Nov., 1835, of poisoning by this acid, in which the diluted aromatic spirit of ammonia applied to the mouth, and the solid carbonate assiduously applied to the nostrils, produced speedy and beneficial effects. Cold affusion was first proposed in 1828 by Herbst, of Göttingen, and its utility was subsequently confirmed by Orfila. Its efficacy is strongly supported by experiments performed in 1839 by Dr. Robinson and M. Lonyet, who quickly resuscitated rabbits, apparently dead from hydrocyanic acid, by pouring on their head and spine a stream of water artificially refrigerated. A case of poisoning reported by Dr. Christison in Feb. 1850, in which the patient recovered, strongly supports the value as a remedy of a stream of cold water, poured upon the head from a moderate height. Messrs. T. & H. Smith, of Edinburgh, have recommended as an antidote a mixture of the sulphates of the protoxide and sesquioxide of iron, swallowed after a solution of carbonate of potassa. So soon as the antidote comes in contact with hydrocyanic acid, sulphate of potassa is formed, and the poison is converted into Prussian blue. This antidote is proposed by the Messrs. Smith for the medicinal acid only. It may be prepared extemporaneously, according to the same chemists, by adding ten grains of sulphate of protoxide of iron and a drachm of the tincture of chloride of iron to a fluidounce of water, contained in one vial, and twenty grains of carbonate of potassa to a fluidounce or two of water in another vial. The patient is made to swallow the solution of carbonate of potassa, and immediately afterwards the mixed ferruginous solution. The quantity of antidote, here mentioned, is estimated to be sufficient to render insoluble nearly two grains of the anhydrous acid.

After death from suspected poison, it is sometimes necessary to ascertain whether the event was caused by this acid. If death has taken place a long time, it would be needless to search for so volatile a poison; but it has been recognised in one instance seven days after death. The best test is that proposed by Liebig in January 1847, consisting in the conversion of the hydrocyanic acid into sulphocyanate of ammonia, which salt is then tested with a sesquioxide salt of iron. Two drops of the acid, so dilute as not to afford the least blue tint with the salts of iron, upon being mixed with a drop of bihydrosulphate of ammonia, and heated upon a watch-glass until the mixture is colourless, yields a solution of sulphocyanate of ammonia, which becomes of a deep blood-red colour upon the addition of the sulphate of sesquioxide of iron, in consequence of the formation of the sulphocyanuret of iron. (*Chem. Gaz.*, April 1, 1847, from Liebig's *Annalen*.) This test is praised by Mr. A. S. Taylor, who found it to act characteristically on two grains of dilute hydrocyanic acid, containing only 1-3930th of a grain of anhydrous acid. To render the test thus delicate, Mr. Taylor deems it necessary to evaporate the liquid gently to dryness, after the addition of the bihydrosulphate of ammonia, in order to bring the sulphocyanate

to the solid state, before adding the iron test, a fractional part of a drop of which will commonly suffice to produce the characteristic colour. In case the acid is mixed with organic matters, Mr. Taylor proposes a modification of Liebig's test as follows. Place the contaminated acid in a watch-glass, and invert over it another, holding in its centre a drop of the bihydrosulphate of ammonia. In from half a minute to ten minutes, without the application of heat, the bihydrosulphate will be converted into the sulphocyanate of ammonia; and upon removing the upper glass, and evaporating its contents to dryness, the addition of the iron test will produce the blood-red colour. B.

ACIDUM MURIATICUM DILUTUM. *U. S.*, *Ed.*, *Dub.* ACIDUM HYDROCHLORICUM DILUTUM. *Lond.* *Diluted Muriatic Acid.*

"Take of Muriatic Acid *four fluidounces;* Distilled Water *twelve fluidounces.* Mix them in a glass vessel. The specific gravity of Diluted Muriatic Acid is 1·046." *U. S.*

The *London* and *Edinburgh* directions are the same as those of the U. S. Pharmacopœia. The London College gives the sp. gr. of the acid at 1·043, and states that a fluidounce of it is saturated by 168 grains of crystallized carbonate of soda. The U. S. and London diluted acids are identical; but the Edinburgh diluted acid is somewhat stronger (1·050), in consequence of the pure muriatic acid of that College having a density of 1·17, instead of 1·16 (*U. S.*, *Lond.*). The *Dublin College* mixes *four fluidounces* of pure muriatic acid with *thirteen* [*fluid*]*ounces* of distilled water, and states the density of the acid to be 1·045.

It is convenient to have an officinal diluted muriatic acid, and, at present, all the Pharmacopœias give a formula for it. The acids of the different Pharmacopœias virtually agree in strength; the variations being practically insignificant. For an account of the medicinal properties of muriatic acid, see *Acidum Muriaticum.* The dose of the diluted acid is from twenty to sixty drops, mixed with water or other convenient vehicle. The Dublin College employs this acid, as a chemical agent, in the preparation of *Calcis Phosphas Præcipitatum.* B.

ACIDUM NITRICUM DILUTUM. *U. S.*, *Lond.*, *Ed.*, *Dub.* *Diluted Nitric Acid.*

"Take of Nitric Acid [sp. gr. 1·42] *a fluidounce;* Distilled Water *six fluidounces.* Mix them in a glass vessel. The specific gravity of Diluted Nitric Acid is 1·07; and 100 grains of it saturate 20 grains of crystallized bicarbonate of potassa." *U. S.*

"Take of Nitric Acid [sp. gr. 1·42] *three fluidounces;* Distilled Water *seventeen fluidounces.* Mix. The sp. gr. is 1·082. A fluidounce of the Acid is saturated by 154 grains of crystallized carbonate of soda." *Lond.*

"Mix together *one fluidounce* of Pure Nitric Acid (D. 1·500), and *nine fluidounces* of Distilled Water. If the Commercial Nitric Acid of D. 1·390 be used, *one fluidounce and five fluidrachms and a half* are required. The density of this diluted acid is 1·077." *Ed.*

"Take of Pure Nitric Acid [sp. gr. 1·5] *four fluidounces;* Distilled Water *twenty-nine* [*fluid*]*ounces.* Mix. The sp. gr. of this Acid is 1·092." *Dub.*

All the Pharmacopœias embrace Diluted Nitric Acid, for convenience in prescribing. The acids of the U. S., London, and Edinburgh Pharmacopœias are nearly of the same strength, being, for equal volumes with the strong acid, a little more than one-tenth its strength. The acid of the Dublin College is somewhat stronger.

The medicinal properties of the diluted acid are the same as those of the strong acid. (See *Acidum Nitricum.*) The dose is from twenty to forty drops three times a day, sufficiently reduced with water at the time of taking it. A diluted nitric acid is used by the Edinburgh College for preparing the red oxide of mer-

cury; but it is directed to have the density of 1·280, and is, therefore, not the officinal diluted acid of that College.

Off. Prep. Plumbi Nitras. B.

ACIDUM NITRICUM PURUM. *Ed., Dub. Pure Nitric Acid.*

"Purify Nitrate of Potash, if necessary, by two or more crystallizations till nitrate of silver does not act on its solution in distilled water. Put into a glass retort *equal weights* of this purified Nitrate and of Sulphuric Acid; and distil into a cool receiver, with a moderate heat from a sand-bath or naked gas-flame, so long as the fused material continues to give off vapour. The pale-yellow Acid thus obtained may be rendered colourless, should this be thought necessary, by heating it gently in a retort." The density of this Acid is 1·5. *Ed.*

In preparing pure nitric acid, the *Dublin College* distils nitre with nearly an equal weight of sulphuric acid; but before the nitre is used, it is dissolved in boiling water, and purified from common salt by the addition of nitrate of silver, so long as it produces a precipitate. The solution is then strained from the chloride of silver, and evaporated to dryness. The pure nitric acid obtained is directed to have the sp. gr. 1·5.

The officinal pure nitric acid is colourless or pale-yellow. If previously diluted with distilled water, it is not affected by solutions of nitrate of silver or nitrate of baryta; the non-action of these tests showing the absence of muriatic and sulphuric acids. As an acid having the sp. gr. of 1·5, it is considered to be a sesquihydrate by Mr. Phillips; consisting of one eq. of dry acid 54, and one and a half eqs. of water 13·5=67·5. This acid is inconveniently strong, and might with advantage be replaced by a pure acid of the density 1·42. This substitution has been made in the U. S. and London Pharmacopœias of 1850 and 1851.

Nitric Acid has been fully treated of under *Acidum Nitricum*, page 40, to which article the reader is referred.

Pharm. Uses. Pure Nitric Acid is used merely as a chemical agent in preparing Calomelas; Ferri Oxidum Nigrum; Ferri Peroxydum Hydratum; Hydrargyri Oxydum Rubrum; Sublimatus Corrosivus; Tinctura Ferri Acetatis; Tinctura Ferri Sesquichloridi.

Off. Prep. Acidum Nitricum Dilutum; Acidum Nitro-muriaticum; Argenti Nitras; Bismuthi Subnitras; Ferri Pernitratis Liquor; Hydrargyri Pernitratis Liquor; Plumbi Nitras; Spiritus Ætheris Nitrici; Unguentum Hydrargyri Nitratis. B.

ACIDUM NITROMURIATICUM. *U. S., Dub. Nitromuriatic Acid.*

"Take of Nitric Acid [sp. gr. 1·42] *four fluidounces;* Muriatic Acid *eight fluidounces.* Mix them in a glass vessel, and, when effervescence has ceased, keep the product in a well-stopped glass bottle, in a cool and dark place." *U. S.*

"Take of Pure Nitric Acid *one fluidounce;* Pure Muriatic Acid *two fluidounces.* Mix in a green glass bottle, furnished with an accurately ground stopper, and keep in a cool place." *Dub.*

Nitromuriatic acid is the *aqua regia* of the earlier chemists, so called from its property of dissolving gold. Nitric and muriatic acids, when mixed together, mutually decompose each other. According to the researches of Gay-Lussac (June 1848), the reaction gives rise to two compounds, in variable proportions, of nitric oxide and chlorine (NO_2Cl_2 and NO_2Cl), mixed with free chlorine; the former being analogous in constitution to nitrous, the latter to hyponitrous acid. The power, however, of nitromuriatic acid to dissolve gold, and similar metals having a weak affinity for oxygen, is owing exclusively to the free chlorine present, and is in nowise dependent on the compounds above referred to, which remain entirely passive during the solution of the metal. (*Journ. de Pharm.*, Aug. 1848.) Adopting the views of Gay-Lussac, the proportion of the acids

for total mutual decomposition would be two eqs. of nitric and six of muriatic acid; and the products would be the two compounds of nitric oxide and chlorine, free chlorine, and water Assuming this proportion, it follows that a large excess of nitric acid is employed in the U. S. formula. According to the same views, the proportion of free chlorine must be variable, dependent upon the relative proportion of the nitric oxide compounds to each other. For every eq. of NO_2Cl_3 formed, one eq. of chlorine will be set free; while for every eq. of NO_3Cl, two eqs. of chlorine will be evolved. The precise circumstances that determine the simultaneous formation of the two nitric oxide compounds, and their constantly varying proportion to each other, have not been pointed out by Gay-Lussac in the paper above referred to. When nitromuriatic acid is made from strong acids, there is always a loss of the nitric oxide compounds and of free chlorine by effervescence, in consequence of these acids not containing sufficient water to hold the gaseous products in solution. Hence the substitution, in the U. S. Pharmacopœia of 1850, of nitric acid of 1·42 for the acid of the density 1·5 is an improvement. At the same time, as the measure of the nitric acid is not increased, its relative excess in the old formula is diminished.

Properties. Nitromuriatic acid has a golden-yellow colour, and emits the smell of chlorine. It possesses the power of dissolving gold and platinum. It should be kept in a cool dark place, on account of its liability to lose chlorine by heat, and to have it converted, by the action of light, into muriatic acid, through the decomposition of water. On account of its tendency to decomposition, it should not be made by the apothecary until wanted for use, and then only in the quantity ordered; care being taken not to transfer it to the bottle until effervescence has ceased, lest the pressure within should drive out the cork. Nitric and muriatic acids, as found in the shops, are sometimes so weak that when mixed they will not readily act on gold-leaf. In this case, their solvent power may be rendered effective by the addition of a little sulphuric acid, which, by its superior attraction for water, concentrates the other acids, and causes immediate action.*

Medical Properties and Uses. Nitromuriatic acid was brought into notice as a remedy, in consequence of the favourable report of its efficacy as an external remedy in hepatitis, made by Dr. Scott, formerly of Bombay. When thus employed, it produces a tingling sensation in the skin, thirst, a peculiar taste in the mouth, and occasional soreness in the gums and plentiful ptyalism; and at the same time stimulates the liver, as is evinced by an increased flow of bile. It is used either by sponging, or in the form of a local or general bath. When applied by sponging, the acid is first diluted so as to have the acidity of strong vinegar. When used as a foot-bath, three gallons of water, contained in a deep narrow wooden tub, may be acidulated with six fluidounces of the acid. In this the feet and legs are to be immersed for twenty minutes or half an hour. The bath may be employed at first daily, and afterwards twice or thrice a week; and the sponging may be used at the same time. The bath is said to be effective in promoting the passage of biliary calculi. The solution, prepared for a bath, as above mentioned, may be used for a week, adding to it daily a pint of water, acidulated with two fluidrachms of the acid, to make up for the waste by evaporation. The bath should have a temperature of about 97° F., which may be attained by heating part of the acid solution, and throwing it back into the remainder. For some good directions for the preparation and use of the nitromuriatic acid bath, by Mr. Ranald Martin, the reader is referred to the *Pharm. Journ. and Trans.* for July, 1851, p. 38.

* In relation to nitromuriatic acid, see a paper in the third volume of the Journal of the Philadelphia College of Pharmacy, by Daniel B. Smith.

Nitromuriatic acid is also used internally, principally in hepatic and syphilitic diseases, and in the oxalic lithiasis. The dose in this case is three or four drops, largely diluted with water. B.

ACIDUM PHOSPHORICUM DILUTUM. *Lond. Diluted Phosphoric Acid.*

"Take of Phosphorus *six drachms;* Nitric Acid [sp. gr. 1·42.] *four fluidounces;* Distilled Water *eight fluidounces.* Add the Phosphorus to the Acid, previously mixed with the Water in a retort placed in a sand-bath; then apply heat until six fluidounces are distilled. Return these into the retort, and again distil six fluidounces, which are to be rejected. Evaporate the remaining liquor in a platinum capsule until only two ounces remain. Lastly, add to the acid, when it is cold, as much distilled water as may be sufficient to make it accurately measure a pint, and mix." *Lond.* The sp. gr. of this acid is 1·064. An Imperial fluidounce of it is saturated by 132 grains of crystallized carbonate of soda, and nothing is thrown down. Imperial measure is used in this formula.

The process for this officinal preparation of the London College may be thus explained. Phosphorus, when added to strong nitric acid, decomposes it with explosion and rapid combustion; but when it is distilled with the diluted acid the action takes place slowly, the phosphorus gradually melts and becomes oxidized, and nitric oxide is evolved. Before, however, the whole of the phosphorus is acidified, the nitric acid will have distilled over; and hence the necessity of returning it into the retort, as directed by the College, in order to complete the acidification of the phosphorus. When this has been completed, all remains of nitric acid are driven off by evaporation in the platinum capsule; and the residue, which contains all the phosphoric acid that can be generated from six drachms of phosphorus, is brought to a standard degree of dilution, by the addition of sufficient distilled water to make it measure an Imperial pint. (See *Acidum Nitricum* and *Phosphorus.*)

Phosphoric acid may be obtained more economically than by the above process, by decomposing phosphate of lime (calcined bones) by sulphuric acid, saturating the superphosphate formed with carbonate of ammonia, which generates phosphate of ammonia in solution with precipitation of phosphate of lime, and finally decomposing the phosphate of ammonia by a red heat in a platinum crucible. The ammonia is thus expelled, and the solid residuum will be monohydrated phosphoric acid (HO,PO_5), called also *metaphosphoric acid, phosphate of water,* and *glacial phosphoric acid* from its resemblance to ice. Phosphoric acid in this form is a white, transparent, fusible solid, slowly soluble in water, and characterized by producing a white precipitate in a solution of albumen. Forty-five and a half grains of this acid, dissolved in a fluidounce of distilled water, form a solution of about the strength of the officinal acid.

Properties. Diluted phosphoric acid is a colourless, inodorous, sour liquid, acting strongly on litmus, and possessing powerful acid properties. Although evaporated so as to become dense, it is not powerfully corrosive like the other mineral acids. According to the late Mr. Phillips, it contains 8·7 per cent. of monohydrated phosphoric acid. (*Trans. of London Pharm. of* 1851, p. 71.) The officinal acid is not precipitated by chloride of barium or nitrate of silver. If precipitates are produced, chloride of barium indicates sulphuric acid or a sulphate; nitrate of silver, muriatic acid or a chloride. Strips of copper or silver are not affected by the acid, nor is it coloured by sulphuretted hydrogen. If carbonate of soda causes a precipitate, phosphate of lime, or some other phosphate insoluble in water, is probably held in solution. The presence of one-tenth of phosphorous acid, or of a minute quantity of arsenic acid, renders the medicinal acid poisonous. (*Weigel and Krug.*) Dry phosphoric acid consists of one eq. of phosphorus 32, and five of oxygen 40=72.

Medical Properties and Uses. Diluted phosphoric acid is deemed tonic and refrigerant. It is preferable in point of flavour to the diluted sulphuric acid, and is less apt to disturb the digestive functions. Various properties have been ascribed to it, such as allaying pain and spasm, strengthening the sexual organs, preventing the morbid secretion of bony matter, and correcting phosphatic deposits in the urine. The last two properties are attributed to its power of dissolving phosphate of lime. It has been recommended in hysteria, in diabetes, and in leucorrhœa when the secreted fluid is thin and acrid. In diabetes Dr. Paris found it to allay the thirst more effectually than any other acid drink. The dose is from twenty drops to a teaspoonful, diluted with water. B.

ACIDUM SULPHURICUM AROMATICUM. *U. S.*, *Ed.*, *Dub.* *Aromatic Sulphuric Acid.* *Elixir of Vitriol.*

"Take of Sulphuric Acid *three fluidounces and a half;* Ginger, in coarse powder, *an ounce;* Cinnamon, in coarse powder, *an ounce and a half;* Alcohol *a sufficient quantity.* Add the Acid gradually to a pint of the Alcohol, and allow the liquor to cool. Mix the Ginger and Cinnamon, and, having put them into a percolator, pour Alcohol gradually upon them until a pint of filtered liquor is obtained. Lastly, mix the diluted acid and the tincture." *U. S.*

"Take of Sulphuric Acid (commercial) *three fluidounces and a half;* Rectified Spirit *a pint and a half* [Imp. meas.]; Cinnamon, in moderately fine powder, *an ounce and a half;* Ginger, in moderately fine powder, *an ounce.* Add the acid gradually to the spirit, let the mixture digest at a very gentle heat for three days in a closed vessel; mix the powders, moisten them with a little of the acid spirit, let the mass rest for twelve hours, and then put it into a percolator and transmit the rest of the acid spirit. This preparation may also be made by digesting the powders for six days in the acid spirit, and then straining the liquor." *Ed.*

The *Dublin* process is substantially the same as the second process of the Edinburgh Pharmacopœia, and therefore need not be copied.

Properties. Aromatic sulphuric acid is a reddish-brown liquid, of a peculiar aromatic odour, and, when sufficiently diluted, of a grateful acid taste. It has been supposed by some to be a kind of ether, its main ingredients justifying such a suspicion; but the late Dr. Duncan, who originally held this opinion, satisfied himself that the alcohol and sulphuric acid, in the proportions here employed, do not produce a single particle of ether. It must, therefore, be viewed merely as sulphuric acid diluted with alcohol, and containing the essential oils of ginger and cinnamon.

Medical Properties and Uses. This valuable preparation, commonly called *elixir of vitriol*, is a simplification of *Mynsicht's acid elixir.* It is tonic and astringent, and affords the most agreeable mode of administering sulphuric acid. It is very much employed in debility with night sweats, in loss of appetite, and in the convalescence from fevers, especially those of the intermittent type. It is often given in conjunction with cinchona, the taste of which it serves to cover, and, by promoting the solubility of the febrifuge principles of the bark, appears to increase its efficacy. (See *Infusum Cinchonæ Compositum.*) In hæmoptysis and other hemorrhages, when not attended with obvious inflammation, it frequently proves useful in stopping the flow of blood. The dose is from ten to thirty drops in a wineglassful of water, repeated two or three times a day. Care must be taken that the teeth are not injured by the acid.

Off. Prep. Infusum Cinchonæ Compositum. B.

ACIDUM SULPHURICUM DILUTUM. *U. S.*, *Lond.*, *Ed.*, *Dub.* *Diluted Sulphuric Acid.*

"Take of Sulphuric Acid *a fluidounce;* Distilled Water *thirteen fluidounces.* Add the Acid gradually to the Water, in a glass vessel, and mix them. The

specific gravity of this acid is 1·09; and 100 grains of it saturate 25 grains of crystallized bicarbonate of potassa." *U. S.*

"Take of Sulphuric Acid *fifteen fluidrachms* [Imp. meas.]; Distilled Water *a pint* [Imp. meas.]. Add the Acid gradually to half a pint of the Water; then pour in sufficient of the remaining Water to fill accurately the measure of a pint, and mix. The sp. gr. is 1·103; and a fluidounce [Imp. meas.] of the Acid is saturated by 216 grains of crystallized carbonate of soda." *Lond.*

"Mix together *one fluidounce* of Sulphuric Acid and *thirteen fluidounces* of Water. The density of this preparation is about 1·090." *Ed.*

"Take of Pure Sulphuric Acid *one fluidounce;* Distilled Water *thirteen* [*fluid*]*ounces.* Mix. The specific gravity of this acid is 1.084." *Dub.*

This preparation is sulphuric acid, diluted to such an extent as to make it convenient for prescription. The *U. S.*, *Edinburgh*, and *Dublin* Pharmacopœias agree in making the strong acid to the water as *one* to *thirteen* in volume, equivalent nearly to *one* to *seven* in weight; but unfortunately the formula of the London College gives an acid considerably stronger. The coincident processes afford an acid containing about 13 per cent. of the strong liquid acid; while the London acid contains 15 per cent., and has a specific gravity as high as 1·103. The strong acid is added gradually to the water, to guard against the too sudden production of heat, which might cause the fracture of the vessel. During the dilution, when commercial sulphuric acid is used, the liquid becomes slightly turbid, and in the course of a few days deposits a grayish-white powder, which is sulphate of lead, and from which the diluted acid should be poured off for use. This noxious salt is thus got rid of, but sulphate of potassa, another impurity in the strong acid, still remains in solution. To avoid these impurities, the Dublin College directs the dilution of *pure* sulphuric acid. The presence of a small portion of sulphate of potassa will do no harm; but if it should be fraudulently introduced into the strong acid to increase its specific gravity, its amount may be ascertained by saturating the acid, after dilution, with ammonia, and expelling by a red heat the sulphate of ammonia formed. Whatever sulphate of potassa is present will remain behind.

Medical Properties and Uses. Diluted sulphuric acid is tonic, refrigerant, and astringent. It is given in low typhoid fevers, and often with advantage. In the convalescence from protracted fevers, it often acts beneficially as a tonic, exciting the appetite and promoting digestion. As an astringent, it is employed in colliquative sweats, passive hemorrhages, and diarrhœas dependent on a relaxed state of the mucous membrane of the intestines. In calculous affections attended with phosphatic sediments, it is the proper remedy, being preferable to muriatic acid, as less apt, by continued use, to disorder the stomach. Externally it is used as an ingredient in gargles for ulcerated sorethroat and for checking excessive ptyalism, and as a wash for cutaneous eruptions and ill-conditioned ulcers. The dose is from ten to thirty drops three times a day, in a wineglassful of plain or sweetened water. It is added with advantage to infusions of cinchona, the organic alkalies of which it tends to hold in solution. As it is apt to injure the teeth, it is best taken by sucking it through a quill. It is much less used in the United States than the elixir of vitriol, which possesses nearly the same medical properties. An elegant form for giving it is the compound infusion of roses. (See *Acidum Sulphuricum Aromaticum* and *Infusum Rosæ Compositum.*)

In the summer of 1851, attention was called by Mr. Buxton, of London, to the remarkable efficacy of diluted sulphuric acid in several forms of diarrhœa, especially choleraic diarrhœa. In October, 1853, Dr. H. W. Fuller, of St. George's Hospital, published a paper in the London *Medical Times and Gazette*, in which he strongly recommends it in choleraic diarrhœa, from his own expe-

rience and that of his friends, in more than ninety cases, without a single failure. The dose employed is half a fluidrachm, diluted with water, given every twenty minutes in ordinary cases; every quarter of an hour in severe cases. The vomiting, purging, and cramps usually cease after the third or fourth dose. For bilious diarrhœa the acid is not a suitable remedy.

Pharm. Uses. Diluted sulphuric acid is used as a chemical agent to prepare Acidum Citricum; Acidum Tartaricum; Aconitia; Antimonii Sulphuretum Præcipitatum; Strychnia.

Off. Prep. Atropiæ Sulphas; Infusum Rosæ Compositum; Morphiæ Sulphas; Potassæ Sulphas; Quinæ Sulphas; Zinci Sulphas. B.

ACIDUM SULPHURICUM PURUM. *Ed., Dub. Pure Sulphuric Acid.*

"If Commercial Sulphuric Acid contain nitrous acid, heat *eight fluidounces* of it with between *ten and fifteen grains* of sugar, at a temperature not quite sufficient to boil the acid, till the dark colour at first produced shall have nearly or altogether disappeared. This process removes nitrous acid. Other impurities may be removed by distillation, which on the small scale is easily managed by boiling the acid, with a few platinum chips, in a glass retort by means of a sand-bath or gas flame, rejecting the first half ounce." *Ed.*

"Take of Oil of Vitriol of Commerce *any convenient quantity.* Introduce it into a small plain retort, containing a few slips of platinum foil, and, passing the beak of the retort into a Florence flask which is to be used as a receiver, with the aid of a small charcoal fire or gas-lamp, distil over one-tenth of the acid. This being rejected, and a fresh receiver of the same kind connected with the retort, let the distillation be resumed, and continued until no more than about an ounce of liquid remains behind. The distilled product should now be transferred to and preserved in a well-stopped bottle. The sp. gr. of this Acid is 1·846." *Dub.*

The object of these processes is the purification of commercial sulphuric acid. This acid contains the sulphates of lead and potassa, amounting not unfrequently to three or four per cent.; and nitrous acid is almost always present. The salts mentioned, not being volatile, are effectually got rid of by distillation, as directed in the formula. The manner of conducting the distillation is explained at *page* 49, under the head of *Acidum Sulphuricum.* The mode of detecting nitrous acid is pointed out at *page* 48. If present in the commercial acid, the Edinburgh College directs, before distilling it, that it should be heated with a small proportion of sugar, according to the plan of Wackenroder. The acid impurity and sugar mutually decompose each other, and the products are dissipated by the heat. The acid is at first rendered dark and opaque, but gradually becomes pale-yellow, if kept for two hours near the boiling point. Nitrous acid is hurtful to the sulphuric, when the latter is used to obtain muriatic acid, which consequently becomes contaminated with chlorine. Hence the Edinburgh College uses *pure* sulphuric acid in the formula for preparing muriatic acid. If the commercial sulphuric acid contain arsenic, it should not be distilled, but rejected. The tests for this impurity are given at *page* 49.

The following tests are given by the Ed. College for pure sulphuric acid. "Density 1·845: colourless: dilution causes no muddiness: solution of sulphate of iron shows no reddening at the line of contact, when poured over it." The negative indication of the last mentioned test shows the absence of nitrous acid.

It is, perhaps, an advantage to have an officinal *pure* sulphuric acid, to be employed in making the preparations containing this acid; in order to avoid the danger of introducing lead into the system, through the use of the commercial acid. It is true that the commercial acid, upon dilution, lets fall the sulphate of

lead: but can we be certain that the precipitate is always removed from the preparations into which the acid enters? When the acid is required as a mere chemical agent, or for forming sulphates, the commercial acid is sufficiently pure.

There is a want of precision in the nomenclature of the officinal sulphuric acids in the Edinburgh Pharmacopœia. The College adopts the names "Acidum Sulphuricum" and "Acidum Sulphuricum Purum," and translates them in three ways in the formulas—"commercial sulphuric acid," "pure sulphuric acid," and "sulphuric acid." The last name is ambiguous, and may mean either the commercial or pure acid; but we shall assume that it is intended to designate the commercial acid.

According to the views here taken, pure sulphuric acid should be used especially in forming "diluted sulphuric acid" and "aromatic sulphuric acid." Nevertheless in neither of these preparations is it employed by the Edinburgh College. Where a dilute acid is required as a chemical agent, and not as a medicine, it might be directed, in the formula, to be formed by the addition of a determinate quantity of water to the commercial acid. While the Edinburgh College has omitted to order "pure sulphuric acid" in making preparations into which the acid enters as an ingredient, it has, with needless refinement, directed it for preparing *Acidum Aceticum* and *Acidum Muriaticum Purum;* though in these preparations it acts merely as a chemical agent.

Off. Prep. Acidum Sulphuricum Aromaticum; Acidum Sulphuricum Dilutum; Potassæ Bisulphas. B.

ACIDUM TANNICUM. *U. S., Lond., Dub. Tannic Acid.*

"Take of Galls, in powder, Ether, each, *a sufficient quantity.* Put into a glass adapter, loosely closed at its lower end with carded cotton, sufficient powdered Galls to fill about one-half of it, and press the powder slightly. Then fit the adapter accurately to the mouth of a receiving vessel, fill it with Ether previously washed with water, and close the upper orifice so as to prevent the escape of the Ether by evaporation. The liquid which passes separates into two unequal portions, of which the lower is much smaller in quantity and much denser than the upper. When the ether ceases to pass, pour fresh portions upon the Galls, until the lower stratum of liquid in the receiver no longer increases. Then separate this from the upper, put it into a capsule, and evaporate with a moderate heat to dryness. Lastly, rub what remains into powder.

"The upper portion of liquid will yield by distillation a quantity of ether, which, when washed with water, may be employed in a subsequent operation." *U. S.*

The *London College* places Tannic Acid in the catalogue of the Materia Medica, prescribing that it shall be prepared from galls. The process of the *Dublin College* is the same as that of the U. S. Pharmacopœia. In relation to the washing of the ether, it gives the more precise direction to incorporate the ether and water by agitation in the proportion of 12 parts, by measure, of the former to 1 of the latter.

The *U. S.* process is that of M. Pelouze. It may be conducted in an ordinary percolator. The ether employed should be that of the shops, containing a small proportion of water, which has been considered necessary to the success of the operation. It has therefore been advised, should the ether contain no water, to wash it with that fluid, which answers the double purpose of depriving it of alcohol and rendering it sufficiently hydrous. To obtain the tannic acid quite pure, the lower stratum may be washed with ether after the separation of the upper, and evaporated in a vacuum with sulphuric acid. The explanation first given of the process was that the water in the ether dissolves the tannic acid, to the exclusion of all the other principles of the galls, and forms a saturated solu-

tion, which separates from the ether, and constitutes the lower stratum in the receiver. But it has been satisfactorily proved that ether as well as water is present in the solution; and the idea was advanced by M. Beral that the tannic acid, ether, and water form a definite compound, which is essentially liquid, and is decomposed during the evaporation; the two fluids escaping, and the solid tannic acid being left behind. M. E. Robiquet considers the liquid not as a definite compound of these ingredients, but simply as a "juxtaposition of water, tannic acid, and ether" in various proportions; founding his belief upon the fact that, at 22° F. the liquid separates into two layers, of which one is ether and the other a watery solution of tannin, while at about 130° F. it is resolved into dry tannin and common sulphuric ether. The upper and larger stratum in the receiver consists of ether, holding colouring matter with a small proportion of gallic and tannic acids in solution. From 30 to 35 per cent. of tannic acid may be obtained from galls by this process, if properly conducted.

According to Sandrock, the presence of water in the ether is unnecessary; and crude ether acts better than the pure, in consequence of the small proportion of alcohol contained in it. If pure ether mixed with one-sixteenth of alcohol be employed as the menstruum, equally satisfactory results are obtained. The alcohol is supposed to operate by rendering the solution of tannin in ether less viscid, and thereby facilitating its percolation. (See *Am. Journ. of Pharm.*, xxv. 446.) Professor Procter informs us that his experience corresponds with that of Sandrock, but that the product is apt to contain a little of the brown colouring matter.

For practical purposes it is unnecessary to obtain the tannic acid quite pure. It is probably sufficiently so when extracted by the following simple process of Leconnet, given in Christison's Dispensatory. The powder of galls is macerated in a bottle, with just enough ether to moisten it, for twenty-four hours, and then expressed in a powerful press; and the process of maceration and expression is repeated, in the same way, until the powder is exhausted. The liquors are mixed, the ether distilled off, and the residue dried by means of a vapour bath. It is stated that 60 per cent. of tannic acid, but very slightly coloured, may be got in this way. As gallic acid exists but in small proportion in galls, being chiefly produced by the reaction of atmospheric air upon tannic acid in the process for extracting it, very little of that principle is found in the ethereal extract, and the amount of colouring matter taken up by the ether, will scarcely interfere with the medicinal efficacy of the preparation.

The term *tannin* was originally applied to a principle or principles existing in many vegetables, having a very astringent taste, and the property of producing a white flocculent precipitate with the solution of gelatin, and a black precipitate with the salts of the sesquioxide of iron. As obtained, however, from different plants, it was found to exhibit some difference of properties; and chemists have recognised two kinds, one existing in oak bark, galls, &c., distinguished by producing a bluish-black precipitate with the salts of the sesquioxide of iron, and the other existing in Peruvian bark, catechu, &c., and characterized by producing a greenish-black or dark-olive precipitate with the same salts. The former is the one which has received most attention, and from an examination of which the characters of tannin have generally been given. It is the substance described in this article. It will probably be found that the latter is essentially distinct from the tannin of galls, and probably different in different vegetables. One striking peculiarity of the tannin of galls is its facility of conversion into gallic acid, which is wanting in some at least of the other varieties. Since the publication of the experiments of M. Pelouze in relation to tannin, this substance has been universally admitted to rank with the acids, and is now, therefore, denominated *tannic acid*. The ordinary variety procured from galls is called, for

the sake of distinction, by some *gallo-tannic acid*, and by others *querci-tannic acid*.

Properties. Pure tannic acid is solid, uncrystallizable, white or slightly yellowish, inodorous, strongly astringent to the taste without bitterness, very soluble in water, much less soluble in alcohol and ether, especially when anhydrous, and insoluble in the fixed and volatile oils. It may be kept unchanged in the solid state; but its aqueous solution, when exposed to the air, gradually becomes turbid, and deposits a crystalline matter, consisting chiefly of gallic acid. During the change, oxygen is absorbed, and an equal volume of carbonic acid disengaged. But, according to M. E. Robiquet, this change does not always take place, and, when it does happen, is ascribable to the presence of pectase in the tannin. (See *Acidum Gallicum*, page 804.) If the solution of tannic acid be boiled for a long time, the pectase loses its property of acting as a ferment, and the solution may be kept indefinitely without change. (*Journ. de Pharm.*, April, 1853, p. 246.) Exposed to heat tannic acid partly melts, swells up, blackens, takes fire, and burns with a brilliant flame. Thrown on red-hot iron it is entirely dissipated. Its solution reddens litmus, and it combines with most of the salifiable bases. With potassa it forms a compound but slightly soluble, and is, therefore, precipitated by this alkali or its carbonates from a solution which is not too dilute, though a certain excess of alkali will cause the precipitate to be redissolved. Its combination with soda is much more soluble; and this alkali affords no precipitate, unless with a very concentrated solution of tannic acid. With ammonia its relations are similar to those with potassa. Baryta, strontia, lime, and magnesia, added in the state of hydrates, form with it compounds of little solubility. The same is the case with most of the metallic oxides, when presented, in the state of salts, to a solution of the tannate of potassa. Many of the metallic salts are precipitated by tannic acid even in the uncombined state, especially those of lead, copper, silver, uranium, chromium, mercury, teroxide of antimony, and protoxide of tin. With the salts of sesquioxide of iron it forms a black precipitate, which is a compound of tannic acid and the sesquioxide, and is the basis of ink. It does not disturb the solutions of the pure salts of protoxide of iron. Several of the alkaline salts precipitate it from its aqueous solution, either by the formation of insoluble compounds, or by simply abstracting the solvent. Tannic acid unites with all the vegetable organic alkalies, forming compounds which are for the most part of a whitish colour, and but very slightly soluble in water; though they are soluble in the vegetable acids, especially the acetic, and in alcohol, and in this latter respect differ from most of the compounds which tannic acid forms with other vegetable principles. On account of this property of tannic acid, it has been employed as a test of the vegetable alkalies; and it is so delicate, that it will throw down a precipitate from their solution, even when too feeble to be disturbed by ammonia. It has an affinity for several acids, and when in solution affords precipitates with the sulphuric, nitric, muriatic, phosphoric, and arsenic acids, but not with the oxalic, tartaric, lactic, acetic, or citric. The precipitates are compounds of tannic acid with the respective acids mentioned, and are soluble in pure water, but insoluble in water with an excess of acid. Hence, in order to insure precipitation, it is necessary to add the acid in excess to the solution of tannic acid. It precipitates also solutions of starch, albumen, and gluten, and forms with gelatin an insoluble compound, which is the basis of leather. Its ultimate constituents are carbon, hydrogen, and oxygen; and its formula, according to Liebig, is $C_{18}H_8O_{12}$ or $C_{18}H_5O_9+3HO$. Mulder, however, from recent investigations, considers it isomeric with gallic acid, and gives its formula $C_{28}H_9O_{17}+HO$. Strecker looks upon it as a compound of gallic acid and sugar, the latter of which is destroyed in the spontaneous change which moistened galls undergo by time. (See *Acidum Gallicum*, page 804.)

Medical Properties and Uses. Tannic acid, being the chief principle of vegetable astringents, is capable of exerting on the system the same effects with this class of medicines, and may be given in the same complaints. It has an advantage over the astringent extracts in the comparative smallness of its dose, which renders it less apt to offend an irritable stomach. In most of the vegetable astringents, it is associated with more or less bitter extractive, or other principle which modifies its operation, and renders the medicine less applicable than it otherwise would be to certain cases, in which there is an indication for pure astringency without any tonic power. Such is particularly the case in the active hemorrhages; and tannic acid, in its separate state, is in these cases preferable to the native combinations in which it ordinarily exists. Dr. Porta, an Italian physician, employed it with great success in the treatment of uterine hemorrhage, and published the results of his experience in 1827. M. Cavalier afterwards used it successfully in the same complaint, and found it effectual also in a case of bleeding from the rectum. It is, without doubt, a useful remedy in most forms of hemorrhage, after a sufficient reduction of arterial action by depletory measures. In diarrhœa it is probably more beneficial than ordinary astringents, as less liable to irritate the stomach and bowels. It has been found beneficial in colliquative sweats, in cases of chronic catarrh with excessive and debilitating expectoration, in the advanced stages of hooping-cough, and in cystirrhœa. The dose for ordinary purposes is from two to five grains, but in urgent cases it may be increased to ten grains. The only disadvantage which has been experienced from it, when taken in excess, is obstinate constipation. Locally, it may be used for all the purposes to which galls or other vegetable astringents are applicable; as for hemorrhages, relaxation of the uvula and chronic inflammation of the fauces, toothache, aphthæ, excessive salivation, leucorrhœa, gleet, gonorrhœa, flabby and phagedenic ulcers, piles, &c. As a wash it may be used in solution, in the proportion of five grains to a fluidounce of water. (*Am. Journ. of Med. Sci., N. S.*, ix. 192.) A Belgian surgeon, M. Hairion, recommends a strong solution, made in the proportion of one part of tannic acid to three of distilled water, as an application in various ophthalmic affections; as acute and chronic inflammation, ulcers and specks on the cornea, swelling of the conjunctiva, &c. (*Journ. de Pharm. et de Chim.*, xviii. 449.) An ointment may be made from it by rubbing two scruples first with twenty minims of water into a paste, and then with an ounce of lard. Given largely to a dog, it caused the urine to become dark-brown and opaque; and this secretion gave evidences of the presence of gallic and pyrogallic acids. (*Chem. Gaz.*, No. 136, p. 231.) W.

ACONITIA. *U. S.*

Aconitia.

"Take of Aconite Root, bruised, *two pounds;* Alcohol *three gallons;* Diluted Sulphuric Acid, Solution of Ammonia, Purified Animal Charcoal, each, *a sufficient quantity.* Boil the Aconite Root with a gallon of the alcohol, in a distillatory apparatus, for an hour. Pour off the liquor, and boil the root in the same manner, and for the same length of time, with another gallon of the Alcohol and the portion distilled. Again pour off the liquor, boil as before with the remaining gallon of the Alcohol and the portion distilled, and decant. Submit the residue to expression, mix all the liquors, distil off the alcohol, and evaporate, by means of a water-bath, to the consistence of an extract. Treat this with distilled water, filter the resulting solution, and evaporate with a gentle heat to the consistence of syrup. To the residue add as much Diluted Sulphuric Acid, mixed with distilled water, as may be sufficient to dissolve the

Aconitia. Precipitate this with Solution of Ammonia, and dissolve the precipitate in Diluted Sulphuric Acid mixed with distilled water as before. Mix the Animal Charcoal with the solution, shake the mixture frequently for fifteen minutes, filter, again precipitate the Aconitia with Solution of Ammonia, and, lastly, wash it with water, and dry it." *U. S.*

Aconitia probably exists in the plant combined with a vegetable acid, forming a soluble salt. In the above process, this is first extracted by alcohol, then taken up from the alcoholic extract by water, and afterwards converted into a sulphate by the addition of dilute sulphuric acid. The sulphate is decomposed by ammonia, which precipitates the aconitia, and this is purified by being once more combined with sulphuric acid, then decolorized by animal charcoal, and again precipitated by ammonia. Care is requisite, in conducting the process, not to add too great an excess of the solution of ammonia, which diminishes the product probably by dissolving the aconitia.*

Properties. Aconitia, when freshly precipitated, is said to be white and in the form of a hydrate; but it speedily parts with its water, and forms a brownish, brittle mass. (Soubeiran, *Trait. de Pharm.*, ii. 716.) It is thought not to be crystallizable. Obtained by evaporating its alcoholic solution, it is described as being in the form of a transparent, colourless mass, having a glassy lustre. In

* The following process, recommended by Mr. F. W. Headland, of London, as being the most satisfactory and the most productive, of those tried by himself, is given in the second edition of *Royle's Manual of Materia Medica*, p. 288. "Take of the root of *Aconitum ferox*, coarsely bruised, two pounds, of *rectified spirit* three gallons. Boil the Aconite with a gallon of the spirit for an hour, in a retort with a receiver adapted to it. Pour off the spirit. Boil the residue with another gallon, and with that which distilled over. Pour off again, and do the same a third time. Press the root, and mix the solutions. Filter. Distil off the spirit from the tincture thus obtained until this is of the consistence of thin syrup. Then pour it out of the retort, and mix with twice its bulk of *distilled water*, and excess of *sulphuric acid*. Filter carefully from the precipitate produced, until it is quite clear. Then again evaporate gently in a water-bath to the consistence of syrup. Pour this syrupy liquid, which should not exceed two fluidounces, into a stoppered bottle, of which it shall occupy about one-third. Add then an excess of *strong solution of ammonia*, and shake gently. To the white mass produced add an equal bulk of pure *ether*. Insert the stopper tightly, and, holding the bottle in a damp cloth, with a finger on the stopper, shake briskly for a few minutes. Allow then a sufficient time for the ether to rise above the water, and, when it has completely separated, remove the stopper, and take up carefully the ethereal solution from the surface of the water with a pipette or common glass syringe. Pour it into an open basin. Again shake up the watery solution with another equal bulk of *ether*, and remove this in the same manner. Do the same a third time. Let the ethereal solution evaporate spontaneously. The Aconitia is deposited.

"This process is quick and certain. It is not difficult; but great care should be taken throughout, on account of the very dangerous nature of the product.

"The *Aconitia* thus prepared is transparent and vitreous in appearance, and of a very light yellow colour, like good gum Arabic. With the exception of this tinge of colouring matter it is quite pure. If required white, it may be again dissolved in a small quantity of acid and water, precipitated by ammonia, and extracted by ether as before. But some of it will be lost by so doing, and there will be no increase in the medicinal virtue of the product."

According to Mr. Headland, the process of the former London Pharmacopœia, which is the one adopted in the U. S. Pharmacopœia, and given in the text, has generally if not invariably proved unsuccessful, even in skilful hands. The defects of this process are mainly the employment of so large an amount of water, the repeated solutions, and the use of animal charcoal, which has the property of absorbing the alkaloids.

The root of *Aconitum ferox*, from the E. Indies, is preferred in consequence of its greater yield. A specimen of this, which we have had the opportunity of examining, was in single roots, fusiform, from two and a half to three and a half inches long, from half an inch to an inch and a half thick at the thickest part near the top, gradually tapering to a point, unequally wrinkled from drying, of a dark-brown colour externally, yellowish internally, hard, with a shining wax-like fracture, and the characteristic taste of the aconites in a high degree.—*Note to the tenth edition.*

powder, it is white when quite pure. It is inodorous, and of a bitter and acrid taste, producing a benumbing impression on the tongue. The acrimony, however, is ascribed by some to a distinct principle associated with it, from which it may be freed by repeated solution in dilute acids and subsequent precipitation. It is unalterable in the air, and fusible by a gentle heat. At a high temperature it is decomposed, with the escape of ammonia, and by a continuance of the heat is entirely dissipated. It is sparingly soluble in water, requiring for solution 150 parts of cold and 50 of boiling water. (*Phillips.*) Alcohol and ether dissolve it readily. It neutralizes the acids; but its salts are not crystallizable. Their solution produces a white precipitate with bichloride of platinum, a yellowish with terchloride of gold, and a yellowish-brown with free iodine. That it contains nitrogen is proved by the evolution of ammonia, when it is decomposed by heat. Dr. A. von Planta gives as its formula $NC_{60}H_{47}O_{14}$. (See *Am. Journ. of Pharm.*, xxiii. 40, from *Liebig's Annalen.*) A spurious substance has sometimes been sold under the same name, which is nearly or quite inert; and at best the alkaloid is apt to be of uncertain strength, as found in the shops.

Medical Properties and Uses. This vegetable principle exercises a powerful influence over the animal economy. One-fiftieth of a grain dissolved in alcohol destroyed a sparrow in a few minutes; and the same quantity administered to an elderly female is said to have nearly proved fatal. In a case of poisoning by aconitia, recorded by Dr. Golding Bird, though two grains and a half were taken, the patient ultimately recovered. But, as vomiting almost immediately ensued, there is reason to believe that much of the poison was thus discharged from the stomach. Besides extreme general prostration, indicated by a cold pale surface, and a scarcely perceptible action of the heart, the prominent symptoms were convulsive vomiting, recurring every minute or two, and fearful spasms of the throat, resembling those of hydrophobia, upon any attempt at swallowing. There was no paralysis, the pupils were sensible to light, and the intellect remained perfectly clear. The remedies were the hot bath, mustard to the epigastrium, and enemata of oil of turpentine, laudanum, and nutriment. (*Lond. Med. Gaz.*, Jan. 1847.) Aconitia is not used internally as a remedy; but Dr. Turnbull has advantageously resorted to its external application. According to this writer, it produces in the skin a sensation of heat and prickling, followed by numbness and a feeling of constriction; and the effect continues, according to the quantity applied, from two to twelve hours or more. He found it not to act as a rubefacient, or at least but slightly so. Applied very much diluted and in minute quantity to the eye, it causes contraction of the pupil, with an almost intolerable sense of heat and tingling. The affections in which Dr. Turnbull employed it with benefit, were neuralgia, gout, and rheumatism. He recommends it either in alcoholic solution, in the proportion of a grain to a fluidrachm, or in the form of an ointment, made by rubbing up two grains of the alkali first with six drops of alcohol, and then with a drachm of lard. These proportions are sufficiently large to begin with, but may be gradually increased to four or five, or even eight grains to the drachm. The preparation should be applied by friction over the part affected, which should be continued till the peculiar sensation above described is produced, and may be repeated three or four times, or more frequently, during the day. No good can be expected unless the sensation alluded to be experienced in a greater or less degree. Care should be taken not to apply the medicine to an abraded surface, or to a mucous membrane, for fear of dangerous constitutional effects. It is very seldom used, and all its beneficial effects can be obtained from safer and cheaper preparations of aconite. W.

ÆTHEREA.

Ethers.

Ethers are peculiar, fragrant, sweetish, very volatile, and inflammable substances, generated for the most part by the action of acids on alcohol. Their composition varies with the acid employed in their formation. Sometimes this merely acts as a chemical agent on the alcohol, without entering into the composition of the ether generated; in which case the ether consists of etherine and water. In other instances the acid employed unites with etherine and water (the ether just mentioned), or with etherine only. On the basis of these differences of composition, the medicinal ethers may be divided into three kinds: 1. those consisting of etherine and water; 2. those consisting of an acid, etherine, and water; and 3. those composed of an acid and etherine only. Hydric ether is the only known ether of the first kind, hyponitrous ether is an example of the second, and muriatic ether of the third. In medicine, the hydric and hyponitrous ethers, and their modifications, are those most commonly employed; though occasionally the acetic and muriatic have been used.

Ethers, from their extreme inflammability, should never be decanted in the vicinity of flame. Hence it is prudent not to pour them out near a lighted candle. They should be kept in accurately stopped bottles in a cool place; otherwise they are liable to considerable loss by evaporation. B.

ÆTHER. *U. S.*, *Lond.* ÆTHER SULPHURICUS. *Ed.*, *Dub.* *Ether. Sulphuric Ether. Hydric Ether.*

"Take of Alcohol *four pints;* Sulphuric Acid *a pint;* Potassa *six drachms;* Distilled Water *three fluidounces.* To two pints of the Alcohol, in an open vessel, add gradually fourteen fluidounces of the Acid, stirring them frequently. Pour the mixture, while still hot, into a tubulated glass retort, placed upon a sand-bath, and connected by a long adapter with a receiver kept cold by ice or water; then raise the heat quickly until the liquid begins to boil. When about half a pint of ethereal liquid has passed over, introduce gradually into the retort the remainder of the alcohol, previously mixed with two fluidounces of the Acid, taking care that the mixture shall enter in a continuous stream, and in such quantity as shall supply the place, as nearly as possible, of the liquid which distils over. This may be accomplished by connecting a vessel containing the alcoholic liquid with the retort, by means of a tube provided with a stop-cock to regulate the discharge, and passing nearly to the bottom of the retort, through a cork accurately fitted into the tubulure. When all the Alcohol has been thus added, continue the distillation until about three pints have passed over, or until white vapours appear in the retort. To the product thus obtained add the potassa previously dissolved in the distilled Water, and shake them frequently. At the end of twenty-four hours, pour off from the alkaline solution the supernatant ether, introduce it into a retort, and, with a gentle heat, distil until two pints have passed over, or until the distilled liquid has the specific gravity 0·750." *U. S.*

"Take of Rectified Spirit *fifty fluidounces;* Sulphuric Acid *ten fluidounces.* Pour twelve fluidounces of the Spirit gently over the Acid contained in an open vessel, and then stir them together briskly and thoroughly. Transfer the mixture immediately into a glass matrass connected with a refrigeratory, and raise the heat quickly to about 280°. As soon as the ethereal fluid begins to distil over, supply fresh spirit through a tube into the matrass in a continuous stream, and in such quantity as to equal that of the fluid which distils over. This is best accomplished by connecting one end of the tube with a graduated vessel

containing the spirit,—passing the other end through a cork fitted into the matrass,—and having a stop-cock on the tube to regulate the discharge. When forty-two [fluid]ounces have distilled over, and the whole spirit has been added, the process may be stopped. Agitate the impure ether with sixteen fluidounces of a saturated solution of muriate of lime, containing about half an ounce of lime recently slaked. When all odour of sulphurous acid has been thus removed, pour off the supernatant liquor, and distil it with a gentle heat so long as the liquid which passes over has a density not above 0·735. More ether of the same strength is then to be obtained from the solution of muriate of lime. From the residuum of both distillations a weaker ether may be obtained in small quantity, which must be rectified by distilling it gently again." *Ed.*

"Take of Rectified Spirit *three pints* [Imp. meas.]; Oil of Vitriol of Commerce *eight fluidounces* [Imp. meas.]; Fresh burned Lime, in fine powder, *one ounce* [avoirdupois]. Mix the Acid in ten ounces of the Spirit in a glass matrass, capable of holding a quart at least, and, without allowing the mixture to cool, connect the matrass with a Liebig's condenser, and, applying a sufficient heat to maintain the liquid in brisk ebullition, commence the distillation. As it proceeds, admit gradually, through a glass tube traversing the cork of the matrass, the remainder of the spirit, regulating its influx so that the boiling liquid shall maintain a constant level; and, when the entire of it has been introduced, continue the application of the heat until the contents of the matrass become black, and show a tendency to froth over. (The tube through which the Spirit enters should dip by its lower extremity, where its diameter is contracted, at least half an inch beneath the surface of the liquid in the matrass; and the eduction pipe of the reservoir for the Spirit, with which the exterior extremity of the glass tube is connected, should be furnished with a stop-cock, to regulate the descent of the Spirit. This reservoir also should be placed at least three feet above the level of the boiling liquid.) The crude Ether thus obtained is to be agitated with the pulverized quicklime, and then rectified; the distillation being continued as long as the product, on being well shaken, continues to have a specific gravity lower than 0·750. The resulting liquid should be preserved in a cool place in accurately stopped bottles. A fresh receiver being attached to the further end of the condenser, and the distillation resumed, a product will be obtained which may be substituted for Rectified Spirit in a subsequent ether process." *Dub.*

In the last sentence of the above process, a misprint occurs in the Dublin Pharmacopœia of the word "reservoir" for receiver, which we have corrected.

The *London College*, in its Pharmacopœia of 1851, has transferred ether to the list of the Materia Medica, giving the following explanatory note and tests. "Ether prepared from alcohol by the action of sulphuric acid. It is free from colour, and its sp. gr. does not exceed 0·750. It wholly evaporates in the air, and reddens litmus slightly or not at all. A fluidounce requires for its complete solution ten fluidounces of water with which it quickly unites."

The preparation of ether embraces two stages; its generation, and its subsequent rectification to remove impurities. The formulas all agree in obtaining it by the action of sulphuric acid on alcohol. In the United States process, which is adopted, with modifications, from that of the French Codex, half the alcohol taken is mixed with seven-eighths of the acid, and, while still hot from the reaction, distilled from a glass retort, by a heat quickly applied, into a refrigerated receiver. When the distilled product equals one-fourth of this portion of the alcohol, the remainder of it, mixed with the reserved eighth of the acid, is allowed to enter the retort in a continuous stream, the supply being so regulated as to equal the amount of the liquid which distils over. By a complicated reaction which will be explained presently, the acid converts the alcohol into ether, and, were it not that the acid becomes more and more dilute as the process pro-

ceeds, it would be able to etherize an unlimited quantity of alcohol. Although the acid, before it becomes too dilute, is capable of determining the decomposition of a certain amount of alcohol, yet it is not expedient to add this amount at once; as a considerable portion of it would distil over undecomposed with the ether. The proper way of proceeding, therefore, is that indicated in the formula; namely, to commence the process with the use of part of the alcohol; and, when the decomposition is fully established, and a portion of ether has distilled, to add the remainder in a gradual manner, so as to replace that which, every moment during the progress of the distillation, is disappearing by its conversion into ether. As, however, the acid in the retort has already become somewhat weaker, it is considered advantageous to mix a small portion of acid with the alcohol which is thus gradually added. When a portion of ether has distilled, equal to about three-fourths of the alcohol employed, or when white vapours appear in the retort, the process is discontinued. These vapours indicate the commencement of a series of reactions different from those which generate the ether.

The *Edinburgh* and *Dublin* processes for the generation of ether are, in their general features, the same with that of the U. S. Pharmacopœia. In the Edinburgh process less than a fourth of the alcohol is placed in the distilling vessel, previously mixed with the *whole* of the acid, which forms one-fifth of the bulk of the alcohol, instead of one-fourth as in the U. S. formula. As soon as the ether begins to distil by a quick heat, the remainder of the alcohol is added in a continuous stream as in the U. S. process; and the distillation is continued until a quantity of ether has come over, equal to somewhat less than six-sevenths of the bulk of all the alcohol. The ether is conveniently condensed by means of Liebig's excellent refrigeratory, described and figured at *page* 793.

The appearance of white vapours in the retort, or the passing over of a heavier portion in the distillation, is the signal for discontinuing the process. If it were continued afterwards, the boiling point would gradually rise, very little ether would be obtained, and at the temperature of 320° there would be generated, in consequence of new reactions, sulphurous acid, heavy oil of wine, olefiant gas, and a large quantity of resino-carbonaceous matter, blackening and rendering thick the residuary liquid; all products arising from the decomposition of a portion of sulphuric acid, alcohol, and ether. Notwithstanding the process may be stopped in time, yet the ether obtained is contaminated with sulphurous acid, heavy oil of wine, alcohol, and water; and hence its purification becomes necessary. This is conducted in various ways, according to the different Pharmacopœias. The U. S. Pharmacopœia directs for this purpose an aqueous solution of potassa, the Edinburgh a saturated solution of chloride of calcium (muriate of lime), to which a portion of recently slaked lime has been added, and the Dublin fresh burned lime. In all cases, the crude ether is agitated with the purifying agent, and submitted to a new distillation at a gentle heat, called the *rectification*.

The purifying substances are potassa for sulphurous acid and water, and water for alcohol in the U. S. formula; lime for acid, and a saturated solution of chloride of calcium for alcohol and water, in the Edinburgh; and lime alone in the Dublin. The Edinburgh substances for purifying are stated by Dr. Christison to be convenient, and to act perfectly and promptly. The chloride of calcium solution, after having been used, yields, on distillation, a further portion of ether of the officinal density; and by concentrating it, filtering while hot, and separating the crystals of sulphite of lime which form on cooling, the chloride may be recovered for future operations.

The process for forming ether is conducted with most advantage on a large scale. At Apothecaries' Hall, where the operation is performed in this way, the apparatus employed is thus described by Mr. Brande. It "consists of a leaden still, heated by means of high pressure steam carried through it in a con-

torted leaden pipe. A tube enters the upper part of the still, for the purpose of suffering alcohol gradually to run into the acid. The still-head is of pewter, and is connected, by about six feet of tin pipe, with a very capacious condensing apparatus, duly cooled by a current of water. The receivers are of pewter, with glass lids, and have a side tube to connect them with the delivering end of the condensing-pipe." (*Manual of Chemistry*, Ed. 1848.)

Properties. Ether is a colourless very limpid liquid, of a strong and sweet odour, and hot pungent taste. As prepared for medical use, it generally reddens litmus slightly, though this is not a property belonging to the pure substance; but if it reddens litmus strongly, it shows that the ether has been imperfectly prepared or too long kept. When perfectly pure it has the specific gravity 0·713, boils at 95°, and forms a vapour which has the density of 2·586. It is not frozen by a cold of 166° below zero. (Faraday, *Philos. Mag. and Journ. of Sci.* for March, 1845.) The officinal strength of the United States ether is 0·750; of the London, 0·750 or under; of the Edinburgh, 0·735 or under; of the Dublin, under 0·750. That sold in the shops varies from 0·733 to 0·765. Its sp. gr. as directed by the French Codex is 0·758. For medicinal purposes its density should not be greater than 0·750. In the opinion of Dr. Christison, it should not exceed 0·735; because, according to that writer, commercial ether is generally of this density, and may be obtained of such purity without difficulty. It is a very volatile liquid, and, when of the sp. gr. 0·720, boils at about 98°. Its extreme volatility causes it to evaporate speedily in the open air, with the production of a considerable degree of cold. When good it evaporates from the hand without leaving a disagreeable odour. Its inflammability is very great, and the products of its combustion are water and carbonic acid. In consequence of this property the greatest care should be used not to bring it in the vicinity of flame, as, for example, a lighted candle, for fear of its taking fire. One of the great advantages of using steam as the source of heat is that it obviates, in a great measure, the danger of its accidental inflammation. When too long kept it undergoes decomposition, and is converted in part into acetic acid. It dissolves iodine and bromine, and sulphur and phosphorus sparingly. The latter substance is generally exhibited in ethereal solution. (See *Phosphorus.*) Its power to dissolve corrosive sublimate makes it a useful agent in the manipulations for detecting that poison. It is also a solvent of volatile and fixed oils, many resins and balsams, tannic acid, caoutchouc, and most of the organic vegetable alkalies. It does not dissolve potassa and soda, in which respect it differs from alcohol. Water dissolves a tenth of its volume of ether, and reciprocally ether takes up about the same proportion of water. When water dissolves more than a tenth of its volume, the ether is shown to contain an undue quantity of water or alcohol, or both. Ether unites in all proportions with alcohol.

Impurities and Tests. The impurities found in ether, besides acids and fixed substances, are alcohol, water, and heavy oil of wine. Acids are detected by litmus and removed by agitation with potassa; and fixed substances, by their remaining upon the evaporation of the ether. Alcohol is an admissible substance in the officinal ethers; for it is contained in the Edinburgh ether, which has the lowest density of them all. If, however, it is present in too large a quantity, the density of the ether will be too high. It may be separated by *washing* the ether, as it is called; that is, agitating it with twice its bulk of water, which will unite with the alcohol, forming a heavier stratum after rest, from which the ether may be poured off. The ether by this treatment dissolves about a tenth of its bulk of water, from which it may be purified by agitation with fresh burnt lime, and subsequent distillation. An easy method for detecting and measuring any alcohol which may be present in ether, is that given by the Edinburgh College; namely, to agitate it in a minim measure, with half its

volume of a concentrated solution of chloride of calcium. This will remove the alcohol, and the reduction of the volume of the ether, when it rises to the surface, will indicate the amount of the former. Heavy oil of wine may be discovered by the ether becoming milky upon being mixed with water.

Composition, and Theory of its Production. Ether consists of four eqs. of carbon, five of hydrogen, and one of oxygen, and its empirical formula is C_4H_5O. In volumes it consists of four volumes of carbon vapour, five volumes of hydrogen, and half a volume of oxygen, condensed into one volume of ether vapour. Its proximate constituents may be considered to be one eq. of etherine and one of water; or, in volumes, one volume of etherine vapour and one volume of aqueous vapour, condensed into one volume. This view makes it a *hydrate of etherine* (C_4H_4+HO). The sp. gr. of its vapour, calculated on this constitution in volume, is 2·5817, which is very near 2·586, the number obtained by experiment. By the generality of chemists, however, the constituents of the etherine, together with the hydrogen of the alleged water, are supposed to form a peculiar radical, consisting of C_4H_5, to which the name of *ethyle* has been given. On this view, ether is an *oxide of ethyle* (C_4H_5+O). This view of its composition is confirmed by Dr. E. Frankland, who has isolated ethyle by acting on iodide of ethyle with zinc. As described by him, it is a colourless, inflammable gas, of the sp. gr. 2, incondensible at zero, but condensible, under a pressure of 2·25 atmospheres at 37·5° F., into a colourless, mobile liquid. Ether is generally called *sulphuric* ether, in allusion to the *sulphuric* acid usually employed in its preparation; but it contains no sulphuric acid, and an identical ether may be obtained by the action of other substances on alcohol. Hence the epithet sulphuric is improperly applied to it; and, accordingly, its name has been changed from *Æther Sulphuricus* to *Æther* in the U. S. and London Pharmacopœias of 1850 and 1851. In allusion to the water which ether is supposed to contain, it is sometimes called *hydric ether*. *Etherine*, considered as a constituent of ether, is a hypothetical 4-4 carbohydrogen (C_4H_4).

With a view to determine in what manner sulphuric acid acts upon alcohol in order to convert it into ether, it is necessary that a comparison should be instituted between the composition of the two latter. Now alcohol is a hydrated oxide of ethyle, and ether, oxide of ethyle without water. It follows, therefore, that to convert alcohol into ether, it is only necessary to abstract the water of the former. The agent in effecting this abstraction is evidently the sulphuric acid, which is known to have a strong affinity for water; but its action is not direct as originally supposed, but intermediate, as was first pointed out by the late Mr. Hennell. This chemist found that, when two eqs. of sulphuric acid and one of alcohol were merely mixed, the acid lost a portion of its saturating power, and a new acid was formed, to which he gave the name of *sulphovinic acid* (the *etherosulphuric acid* of Liebig). In view of its composition it may be called a bisulphate of alcohol, or, which is the same thing, a bisulphate of ether with one eq. of water, that is, a double sulphate of ether and water. When one eq. of this acid is heated it is decomposed; two eqs. of sulphuric acid with one eq. of water remain in the retort, while one eq. of ether distils over.

If the original proportion of acid and alcohol continued the same throughout the whole of the distillation, all the alcohol would be resolved into ether and water; but, during the progress of the process, the alcohol is constantly diminishing, and of course the relative excess of the acid becoming greater; and at last a point of time arrives when the excess of acid is so great that the generation of ether ceases. As these results depend upon the relative deficiency of the alcohol, while the acid remains but slightly changed in amount, it is easy to understand why it is advantageous to add alcohol gradually to the distilling vessel during the progress of the distillation; for, by this addition, the proper

proportion of the alcohol to the acid is maintained. But the decomposing power of the acid has its limit; as it becomes at last too dilute to act upon the alcohol, notwithstanding a considerable portion of water, towards the close of the distillation, passes over with the ether.

The theory here given of etherification is at present (1851) called in question. Prof. Graham, of London, has succeeded in producing ether without distillation or the formation of sulphovinic acid, using a larger proportion of alcohol than is ordinarily employed. The reaction was made to take place in sealed glass tubes, heated for a short time to a temperature between 284° and 352°. The sulphuric acid appears to act by mere contact with the alcohol, in determining the production of ether, without combining with anything.

Medical Properties and Uses. Ether is a powerful diffusible stimulant, possessed also of expectorant, antispasmodic, and narcotic properties. In low fevers attended with subsultus tendinum, it proves beneficial as a stimulant and antispasmodic. In these cases it is frequently conjoined with laudanum. It is useful also in nervous headache unattended with vascular fulness, and generally in nervous and painful diseases which are unaccompanied by inflammation. In nausea it is given as a cordial; and in cramp of the stomach and flatulent colic, it sometimes acts with singular efficacy. It is also useful, given alone, or mixed with oil of turpentine, in relieving the pain and spasm caused by the passage of biliary calculi. According to Mr. Brande, a small teaspoonful of ether, mixed with a glass of white wine, is often an effectual remedy in sea-sickness. When externally applied it may act either as a stimulant or refrigerant. If its evaporation be repressed, it operates as a powerful rubefacient, and may even vesicate; but, when this is allowed to take place freely, it is refrigerant in consequence of the cold which it produces. In the latter way it is sometimes employed in strangulated hernia, dropped on the tumour and allowed to evaporate. It sometimes produces immediate relief when dropped into the ear in earache. For external use, the unrectified ether may be employed. The dose of sulphuric ether is from fifty drops to a teaspoonful, to be repeated frequently when the full effect of the remedy is desired. When used habitually the dose must be much larger, to produce a given effect. It may be perfectly incorporated with water or any aqueous mixture, by first rubbing it up with spermaceti, employed in the proportion of two grains for each fluidrachm of the ether. (*Durand.*)

Ether is conveniently administered in capsules, each containing four or five drops, according to the plan of M. Clertan, of Dijon. The ether capsules are inodorous, will keep for a year at least without loss, and furnish the means of introducing ether into the stomach, without irritating the mouth and throat.

Ether may be exhibited by inhalation. Many years ago, its use in this way was proposed by Drs. Beddoes, Pearson, and Thornton, in England, as a remedy in certain diseases of the lungs. As early as 1805, Dr. Warren, of Boston, employed ethereal inhalation to relieve the distress attending the last stage of pulmonary inflammation. About the year 1812, in Philadelphia, at a time when the nitrous oxide was the subject of popular lectures, the vapour of ether was frequently breathed from a bladder for experiment or diversion; and its effects in producing a transient intoxication, analogous to that caused by the nitrous oxide, were observed. It was not, however, until October, 1846, that attention was particularly drawn to ethereal inhalation as a remedy for pain. In that month, Dr. Warren, of Boston, was applied to by Dr. W. T. G. Morton, dentist of the same city, to ascertain by trial whether an agent which he had successfully employed to render painless the extracting of teeth, would be equally successful in preventing the pain of surgical operations. This agent is now known to have been the vapour of ether. Dr. Warren acceded to this request, and shortly afterwards, at the Massachusetts General Hospital, performed a severe

operation, without pain to the patient, under the influence of ether, administered by Dr. Morton. A few days subsequently, Dr. C. T. Jackson, of Boston, in conversation with Dr. Warren, claimed to have first made known to Dr. Morton the use of ethereal vapour for the prevention of pain in dental operations.

From this beginning, the employment of ether by inhalation for the prevention and removal of pain, has spread throughout the civilized world. The effect produced, called *etherization*, probably takes place through the medium of the blood. It is sometimes partial, suspending sensibility, without abolishing consciousness; so that the patient, without feeling pain, is aware of everything that is passing around him. At other times, a perfect unconsciousness is produced.

Etherization is usefully resorted to in all severe operations, not merely as a remedy for pain, but as a means of preventing the shock which the system would otherwise suffer as a consequence of pain. Under full etherization, even the actual cautery may be extensively applied, without causing the least suffering. In many cases, the incidental power of ethereal vapour as a relaxing agent is usefully brought into play; as in the treatment of strictures of the urethra and œsophagus, strangulated hernia, retention of urine, dislocations, fractures, anchylosis, &c. In all these cases, the necessary surgical manipulations are very much interfered with by the muscular contractions excited by pain. This is particularly the case in dislocations, and in fractures attended with shortening of the limb. In partial anchylosis, etherization enables the surgeon in many cases to break up the adhesions, without pain to the patient, or resistance from the muscles. Even in lithotomy and lithotrity, the incidental advantage is gained of preventing or lessening the inordinate contraction of the muscular coat of the bladder. In short, in most cases in which the necessary surgical measures are likely to involve severe pain, or to encounter resistance, as in children, etherization may be usefully employed.

Etherization has been employed for the detection of feigned diseases, as a means of suspending the operation of the will; in neuralgia, as a palliative; in tetanus and in the spasms produced by an over-dose of strychnia, as an antispasmodic; in asthma and chronic bronchitis, as an expectorant; and in dysmenorrhœa, as an anodyne and relaxing remedy. Dr. Warren found it useful in relieving the agonizing sufferings which often attend the latter complaint. In vivisections, humanity calls for the use of ether vapour or other anæsthetic agent.

Etherization, employed in midwifery as an anæsthetic, is growing in favour as a safe agent; and, while it does not seem materially to interfere with the due contraction of the uterus, it promotes the relaxation and lubricating secretions of the soft parts.

Ethereal vapour is most conveniently inhaled through a soft sponge, hollowed out on one side to receive the projection of the nose, and saturated with ether of the purest quality. The sponge, thus prepared, is applied over the nostrils, through which the inhalation should be made in preference to the mouth. When the inhalation is thus conducted through a sponge, the ethereal vapour is copiously mixed with air, and there is no fear of inducing asphyxia. At first a short cough is generally produced, but this soon disappears; and after a lapse of from two to five minutes, and the expenditure of about two fluidounces of ether, the quantity being very variable in different cases, the patient becomes insensible, and appears as if in a deep, almost apoplectic sleep. The usual signs of the full effect of the ether are the closure of the eyelids, muscular relaxation, and inability to answer questions. During the whole process of etherization, the fingers should be kept on the pulse; and, in case it becomes feeble and very slow, the sponge should be removed until the circulation becomes more free. At first there is redness, afterwards paleness of the face and neck, succeeded by

cold perspirations. In case the etherization proves excessive, or convulsions supervene, an event which rarely happens, the ether must be immediately withdrawn, and cold water freely applied. This is the mode of proceeding in surgical operations; in midwifery cases, partial etherization is often sufficient. In a few cases persons become unmanageable under the operation of the ethereal vapour; and hence the propriety of a preliminary trial of its effects on a patient, before submitting him to a surgical operation. Sometimes death has ensued from ethereal inhalation; but the number of fatal cases has been small, compared with the great number of instances in which ether has been used in this way. (See the *Treatise on Etherization*, by John C. Warren, M.D., Boston, 1848.)

Pharm. Uses. Ether is used as a chemical agent in preparing Acidum Tannicum; Extractum Cubebæ Fluidum; Extractum Piperis Fluidum; Extractum Valerianæ Fluidum; Morphiæ Acetas.

OLEUM ÆTHEREUM. *U.S.*, *Lond.* *Ethereal Oil. Heavy Oil of Wine. Sulphate of Ether and Etherine.*

"Take of Alcohol *two pints;* Sulphuric Acid *three pints;* Solution of Potassa *half a fluidounce;* Distilled Water *a fluidounce.* Mix the Acid cautiously with the Alcohol, and allow the mixture to stand twelve hours; then pour it into a large glass retort, to which a receiver kept cool by ice or water is adapted, and distil by means of a sand-bath until a black froth rises, when the retort is to be removed immediately from the sand-bath. Separate the lighter supernatant liquid in the receiver from the heavier, and expose it to the air for a day; then add to it the Solution of Potassa previously mixed with the Distilled Water, and shake them together. Lastly, separate the Ethereal Oil as soon as it has subsided. The specific gravity of Ethereal Oil is 1·096." *U. S.*

"Take of Rectified Spirit *two pints* [Imp. meas.]; Sulphuric Acid *thirty-six fluidounces* [Imp. meas.]; Solution of Potassa, Distilled Water, each, *a fluidounce* [Imp. meas.], or as much as may be sufficient. Mix the Acid cautiously with the Spirit. Let the liquor distil until a black froth arises; then immediately remove the retort from the fire. Separate the lighter supernatant liquor, and expose it to the air for a day. Add to this the Solution of Potassa previously mixed with the Water, and shake them together. Lastly, when sufficiently washed, separate the Ethereal Oil which subsides. The specific gravity is 1·05." *Lond.*

When alcohol is distilled with a large excess of sulphuric acid, the same products are generated as those mentioned in the last article as being formed towards the close of the distillation of ether. (See *page* 827.) These were stated to be sulphurous acid, heavy oil of wine, olefiant gas, and carbonaceous matter. In the *U. S.* process such an excess of sulphuric acid is employed, for the purpose of obtaining the oil. The product of the distillation is in two layers, a heavier one, consisting of water holding sulphurous acid in solution, and a lighter, formed of ether containing the oil of wine. The lighter liquid is separated and exposed for twenty-four hours to the air, in order to dissipate the ether by evaporation; and the oil which is left is shaken with a dilute solution of potassa to deprive it of all traces of sulphurous acid; after which, as soon as it subsides, it is to be separated. The *London* process is substantially the same as that of the U. S. Pharmacopœia. The differences are, that the London College omits to direct a prolonged contact between the alcohol and acid, and dispenses with a refrigerated receiver.

The nature and mode of formation of heavy oil of wine are not well understood. It has been explained, in the preceding article that, in the early stage of the distillation of a mixture of sulphuric acid and alcohol, sulphovinic acid, or double sulphate of ether and water is formed. During its progress this is

decomposed so as to yield ether. When, however, the alcohol is distilled with a large excess of sulphuric acid, the sulphovinic acid is decomposed so as to form a small quantity of the heavy oil of wine, now considered to be a double sulphate of ether and etherine, having the formula $C_4H_5O,SO_3+C_4H_4,SO_3$. It is conceived to be generated from two eqs. of sulphovinic acid (double sulphate of ether and water), which are resolved into one eq. of heavy oil of wine, two of sulphuric acid, and three of water. When the heavy oil is gently heated with four parts of water, sulphovinic acid is reproduced, and the separated etherine floats on the surface as an oily substance, called, when thus isolated, *light oil of wine*. Light oil of wine, as thus obtained, consists of two substances, which are separated from each other by time; namely, a thick oil called *etherole*, and a concrete substance in crystals, isomeric with it, called *concrete oil of wine*, or *oil of wine camphor*, injudiciously denominated etherine by some chemists.

Properties. The *officinal ethereal oil* is a yellowish liquid, possessing an oleaginous consistency, a penetrating aromatic odour, and rather sharp and bitter taste. It boils at 540°. Its sp. gr. is, according to the U. S. Pharmacopœia, 1·096, according to the London College, after Mr. Hennell's results, 1·05. By Dumas and Serullas its density is stated to be as high as 1·133, which is probably the more correct number for the *pure* oil. When dropped into water it sinks, assuming the form of a globule. It is very sparingly soluble in water, but readily dissolves in alcohol and ether. It is devoid of acid reaction, the sulphuric acid present in it being completely neutralized by the ether and etherine united with it. The sulphuric acid present is not precipitated by the usual reagents; because they furnish a base, which, replacing the etherine, gives rise to one of the salts of sulphovinic acid, all of which are soluble in water and hydrous alcohol. The process by which the heavy oil of wine is formed yields but a small product, being only about one part in weight to thirty-one of the alcohol employed, even when performed on the large scale; and, when conducted on the small scale of the Pharmacopœias, the product is only one part of the oil to about seventy-five of the alcohol. *Etherole* is a pale-yellow oily liquid, having an aromatic odour. Its sp. gr. is 0·921, boiling point 500°, and freezing point 31° below zero. It communicates a greasy stain to paper. *Concrete oil of wine* crystallizes in long, transparent, brilliant, tasteless prisms, soluble in alcohol and ether, insoluble in water, fusible at 230°, boiling at 464°, and having the sp. gr. 0·980.

Composition, &c. The officinal oil of wine is essentially the double sulphate of ether and etherine, or heavy oil of wine; but, as prepared by the officinal formula, it always contains more or less light oil of wine, in addition to that present in the heavy oil. This fact accounts for the different densities assigned to the officinal oil by different authorities.

The article sold in our shops as ethereal oil, is generally a mixture of alcohol and ether, with but a trace of the oil. Four samples of so-called ethereal oil, as imported from England, were examined by Mr. E. N. Kent, of New York, and found to have the composition above stated. (*N. Y. Journ. of Pharm.*, i. 65.) It is much to be wished that our manufacturing chemists would make the officinal ethereal oil for the apothecaries, who could then prepare the genuine compound spirit of ether (Hoffmann's anodyne) for themselves.

SPIRITUS ÆTHERIS SULPHURICI. *Ed.* *Spirit of Sulphuric Ether.*

"Take of Sulphuric Ether *a pint;* Rectified Spirit *two pints.* Mix them. The density of this preparation ought to be 0·809." *Ed.*

This preparation is merely ether diluted with twice its volume of alcohol.

When prepared with materials of proper strength, its sp. gr. is 0·809. Its medical properties are similar to those of ether. The dose is from one to three fluidrachms, given with a sufficient quantity of sweetened water.

Off. Prep. Tinctura Lobeliæ Ætherea. B.

SPIRITUS ÆTHERIS COMPOSITUS. *U. S.*, *Lond.* SPIRITUS ÆTHEREUS OLEOSUS. *Dub.* *Compound Spirit of Ether. Hoffmann's Anodyne Liquor.*

"Take of Ether *half a pint;* Alcohol *a pint;* Ethereal Oil *three fluidrachms.* Mix them." *U. S.*

"Take of Ether *eight fluidounces;* Rectified Spirit *sixteen fluidounces;* Ethereal Oil *three fluidrachms.* Mix them." *Lond.*

"Take of Rectified Spirit *one pint and a half* [Imp. meas.]; Oil of Vitriol of Commerce *one pint and a half* [Imp. meas.]; Sulphuric Ether *five fluidounces* [Imp. meas.]. Mix the Oil of Vitriol with one pint of the Rectified Spirit, in a matrass of glass, and, connecting this with a Liebig's condenser, apply heat, and distil, till a black froth begins to rise. Separate the uppermost or lighter stratum of the distilled liquid, and having exposed it in a capsule for twenty-four hours to the atmosphere, let the residual oil be transferred to a moist paper filter, and washed with a little cold water, so as to remove any adhering acid. Let it now be introduced into a bottle, containing the remainder of the Spirit mixed with the Ether, and dissolved." *Dub.*

This preparation is an alcoholic solution of ether, impregnated with ethereal oil. In the U. S. and London Pharmacopœias, determinate measures of ether, alcohol and oil are taken, the ether having half the volume of the alcohol. In the Dublin formula, the same relation is preserved between the ether and alcohol; but as the Dublin College has no separate formula for ethereal oil, it mixes five fluidounces of ether and ten fluidounces of alcohol with all the oil produced by the reaction of thirty fluidounces of sulphuric acid on twenty of alcohol. The objections to this process are that the quantity of ethereal oil produced is uncertain, and that washing alone is employed for its purification.

Compound spirit of ether is a volatile liquid, having a burning, slightly sweetish taste, and the peculiar odour of ethereal oil. Its sp. gr. is 0·816, according to the U. S. Pharmacopœia. When pure it is wholly volatilized by heat, and devoid of acid reaction. It becomes milky on being mixed with water, owing to the precipitation of the ethereal oil; but this change does not prove its goodness, as the same property may be given to the spirit of sulphuric ether by the addition of various fixed oils. This sophistication may be detected, according to Prof. Procter, by mixing the suspected preparation with water, drawing a piece of paper over the surface of the liquid to absorb the oily globules, and exposing the paper to heat. If the globules are fixed oil, the greasy stain will be permanent; if ethereal oil, the stain will disappear.

It is much to be regretted that our manufacturing chemists do not follow the Pharmacopœia in making Hoffmann's anodyne. In rectifying crude ether, the distillation is continued, so long as the ether comes over of the proper specific gravity; after which the receiver is changed, and an additional distillate is obtained, consisting of ether and alcohol, impregnated with ethereal oil. Now it is this second distillate, variously modified by the addition of alcohol, ether, or water, so as to make it conform in taste, smell, opalescence, &c., to a standard preparation, that the manufacturer sells as Hoffmann's anodyne. (See Prof. Procter's paper on Hoffmann's anodyne in the *Am. Journ. of Pharm.* for July, 1852, p. 213.) Nothing could be more uncertain in its results than a proceeding like this; and we cannot be surprised that the medicine, as obtained from different apothecaries, varies very much in properties, and often disappoints the expecta-

tions of the physician. The chief excuse for the departure from the officinal directions is the costliness of the ethereal oil; but it can be shown that the oil at nine dollars an avoirdupois pound would increase the cost of a pint and a half of the preparation only twenty-two cents.

Medical Properties. This preparation is intended as a substitute for the anodyne liquor of Hoffmann, which it closely resembles. In addition to the stimulating and antispasmodic qualities of the ether which it contains, it possesses anodyne properties, highly useful in nervous irritation, and want of sleep from this cause. These additional virtues are probably derived from the officinal oil of wine, which is a more important substance than is generally supposed. Mr. Brande supposes that the only effect of it, in the preparation under notice, is to alter the flavour of the ether. In this opinion he is certainly in error. Dr. Hare, in his Chemical Compendium, reports the opinion of Drs. Physick and Dewees in favour of the efficacy of the officinal oil of wine, dissolved in alcohol, in certain disturbed states of the system, as a tranquillizing and anodyne remedy. Such indeed are the generally admitted effects of Hoffmann's anodyne, when made with a due admixture of the ethereal oil. Hoffmann's anodyne is on many occasions a useful adjunct to laudanum, to prevent the nausea which is excited by the latter in certain habits. Its dose is from one to two fluidrachms, given in water sweetened with sugar. B.

SPIRITUS ÆTHERIS NITRICI. *U. S.*, *Lond.*, *Ed.* Spiritus Ætherеus Nitrosus. *Dub.* Spiritus Nitri Dulcis. *Spirit of Nitric Ether. Sweet Spirit of Nitre.*

"Take of Nitrate of Potassa, in coarse powder, *two pounds;* Sulphuric Acid *a pound and a half;* Alcohol *nine pints and a half;* Diluted Alcohol *a pint;* Carbonate of Potassa *an ounce.* Mix the Nitrate of Potassa and the Alcohol in a large glass retort, and, having gradually poured in the Acid, digest with a gentle heat for two hours; then raise the heat and distil a gallon. To the distilled liquor add the Diluted Alcohol and Carbonate of Potassa, and again distil a gallon." *U. S.*

"Take of Rectified Spirit *forty fluidounces;* Nitric Acid [sp gr. 1·42] *three fluidounces and a half.* Add the Acid gradually to the Spirit and mix them; then distil *twenty-eight fluidounces.*" *Lond.*

"Take of Rectified Spirit *two pints and six fluidounces* [Imperial measure]; Pure Nitric Acid (D. 1·500) *seven fluidounces* [Imp. meas.]. Put fifteen fluidounces of the Spirit, with a little clean sand, into a two pint matrass, fitted with a cork, through which are passed a safety-tube terminating an inch above the Spirit, and another tube leading to a refrigeratory. The safety-tube being filled with Pure Nitric Acid, add through it gradually three fluidounces and a half of the acid. When the ebullition which slowly rises is nearly over, add the rest of the acid gradually, half a fluidounce at a time, waiting till the ebullition caused by each portion is nearly over before adding more, and cooling the refrigeratory with a stream of water, iced in summer. The ether thus distilled over, being received in a bottle, is to be agitated first with a little milk of lime, till it ceases to redden litmus paper, and then with half its volume of concentrated solution of muriate of lime. The pure hyponitrous ether thus obtained, which should have a density of 0·899, is then to be mixed with the remainder of the Rectified Spirit, or exactly four times its volume. Spirit of Nitric Ether ought not to be kept long, as it always undergoes decomposition, and becomes at length strongly acid. Its density by this process is 0·847." *Ed.*

"Take of Rectified Spirit *forty-eight fluidounces;* Pure Nitric Acid *three fluidounces;* Water *one* [*fluid*]*ounce;* Solution of Ammonia *a sufficient quantity.* Place six [fluid]ounces of the Spirit in a glass matrass capable of holding forty

fluidounces, and connect this with a Liebig's condenser, whose further extremity is fitted loosely by a collar of tow into a thin eight ounce vial. Add now the Water to the Nitric Acid, and, having introduced half of the resulting solution into the matrass, through a safety syphon tube, close the mouth of this tube with a cork, and apply for a few moments a gentle heat, so as to cause a commencement of ebullition. When the *action* (which, shortly after commencing, proceeds with much violence, and should be moderated by the external application of cold water) has relaxed, introduce gradually the remainder of the Acid, so as to restore it. The action having entirely ceased, agitate the distilled product with half its bulk of the Solution of Ammonia, allow the mixture to rest for a few minutes, and, having separated the supernatant ethereal liquid, mix four [fluid]ounces of it with the rest of the Spirit, and preserve the product in small, strong, and accurately stopped bottles. In the performance of the preceding distillation, the condenser should be fed with ice-cold water, and the vial, in which the distilled liquid is received, should be surrounded by a mixture of one part salt and two of pounded ice; or, when ice cannot be procured, with a mixture of eight parts of sulphate of soda in small crystals and five of commercial muriatic acid." *Dub.*

The officinal spirit of nitric ether is a mixture, in variable proportions, of hyponitrous ether and alcohol (rectified spirit). Hyponitrous ether is always generated by the reaction of nitric acid and alcohol; and it matters not whether the alcohol be mixed with nitric acid directly, or with the materials for generating it, namely, nitre and sulphuric acid. When the materials for forming the ether contain an excess of alcohol, this distils over with the ether, and forms the preparation under consideration.

The processes of the Pharmacopœias differ considerably. The U. S. Pharmacopœia obtains the requisite nitric acid by using the materials for generating it; while the British Colleges mix the acid ready formed with the alcohol. The London process, however, differs from the Edinburgh and Dublin in one important point; namely, that while the London College distils the nitric acid with an excess of alcohol, which comes over largely with the ether, forming, at once, the sweet spirit of nitre; the other Colleges form a concentrated hyponitrous ether, and dilute it with a determinate quantity of alcohol.

The *United States* formula is modeled after a recipe communicated by Mr. John Carter, manufacturing chemist, to the Philadelphia College of Pharmacy, and recommended for adoption by a committee of that body. The nitre and alcohol being mixed in the retort, the sulphuric acid is gradually added, and a gentle heat applied. Nitric acid is set free, and by reacting with a part of the alcohol produces the hyponitrous ether. Upon the subsequent increase of the heat, the ether and the remainder of the alcohol distil over as the sweet spirit of nitre. The distilled product, however, contains some acid, and hence is rectified by a distillation from carbonate of potassa. The diluted alcohol is added before commencing this distillation, to enable the operator to obtain a quantity of distilled product equal to that procured at first, without distilling to dryness, which would endanger the production of empyreuma. The alcohol is first mixed with the nitre, and the sulphuric acid afterwards gradually added. Were the alcohol and sulphuric acid previously mixed, the risk would be run of generating ether, before their addition to the nitre in the retort. The retort should be of such a size as to be capable of holding twice the amount of the materials employed.

The above process, as conducted by Mr. Carter on a large scale, is performed in a copper still of about twenty gallons capacity, and furnished with a pewter head and worm. The materials for the first distillation are 18 pounds of purified nitre, 12 gallons of alcohol of 34° Baumé (0·847), and 12 pounds of sulphuric acid; and 10 gallons are drawn off. The distilled product is then mixed with

a gallon of diluted alcohol, and rectified by a new distillation from lime or a carbonated alkali; the same quantity being distilled as at first. When large quantities of this preparation are thus obtained, the several portions require to be mixed in a large glass vessel, to render the whole of uniform strength; as the portion which first comes over in the rectification is strongest in hyponitrous ether. Previously to the redistillation, the head and worm must be washed thoroughly with water to remove a little acid which comes over in the first distillation. (*Journ. of the Phil. Col. of Pharm.*, i. 308.)

In the *London* process, nitric acid, ready formed, is mixed with the alcohol; the proportion of acid to the spirit being as 7 to 80 in volume. The proportion of liberated nitric acid to the alcohol in the U. S. formula may be assumed to be the same as that in the London process; since the preparation obtained by the two processes has the same specific gravity. The proportion of sweet spirit of nitre by measure drawn off to the alcohol employed is seven-tenths in the London formula, and about five-sixths in that of the U. S. Pharmacopœia. When the distillation is pushed too far, the product is high-coloured, specifically heavier than it should be, very acid so as to act strongly on litmus paper, decomposes the alkaline carbonates with effervescence, and contains aldehyd, which gives it a pungent odour. (*Dr. Golding Bird.*) The impurities arising from a distillation carried too far may, according to Dr. Bird, be entirely avoided by following the directions of the London Pharmacopœia. The residue of the process, if further distilled, will yield a small additional portion of sweet spirit of nitre, nearly pure, of higher specific gravity than the officinal portion; but, on continuing the process, the hyponitrous ether ceases to come over, and about the same time aldehyd appears in the distilled product, and in the residue, oxalic acid, which replaces the oxalhydric (saccharic) acid, formed at an earlier stage of the reaction. Admitting Dr. Bird's results, it is probable that the sweet spirit of nitre which comes over in the first distillation of the U. S. process will contain aldehyd; as considerably more liquid is drawn over than is distilled in the London process. Supposing this to be the case, it is presumable that this impurity would be separated, together with any contaminating acid, by the second distillation from carbonate of potassa. According to Mr. Alsop and Mr. Scanlan, of London, the process of the London College is a precarious one, and at the same time not economical. (*Pharm. Journ. and Trans.*, iii. 425.) It is probably not economical, but it gives a good preparation when the London College directions are strictly complied with.

The *Edinburgh* process for sweet spirit of nitre consists of two steps: first, the formation of hyponitrous ether, and, secondly, its dilution with four times its volume of alcohol. Dr. Christison, commenting on this process, states that it may be conducted with safety and despatch, when the precautions are attended to which are enjoined by the Edinburgh College. The conditions for success are to add no more acid to the spirit at first than what is necessary to commence the action; to wait until the ebullition thus arising shall have ceased; to add the rest of the acid in small successive portions; to let the acid drop from the height of about an inch into the spirit; to have some clean sand in the bottom of the matrass; and to employ a refrigeratory, such as that figured at *page* 793. Should the ebullition increase too rapidly, it may be repressed by blowing cool air across the matrass. The presence of the sand prevents the dangerous succussions arising from the sudden liberation of ethereal vapour. The ethereal product is first agitated with milk of lime to separate acid, and then with half its volume of a concentrated solution of chloride of calcium, to remove water and alcohol. The density given for this hyponitrous ether is 0·899, which is lower than that of the pure ether. The last step in the process is to mix this ether with the prescribed quantity of alcohol, which gives a sweet spirit of nitre of the density of

0·847. The hyponitrous ether of this process may be presumed to measure, on an average, $7\frac{3}{4}$ fluidounces, and, consequently, the sweet spirit of nitre obtained from it $38\frac{3}{4}$ fluidounces. The degree of dilution was fixed, so as to make it conform in ethereal strength with the same preparation of the former Edinburgh Pharmacopœia. The preparation is intended to contain one-fifth of its volume of ether, and is probably between three and four times as strong as the sweet spirit of nitre of the U. S. and London Pharmacopœias. For making this preparation, Dr. Christison prefers the present plan of the Edinburgh College, of diluting the pure hyponitrous ether to a determinate degree, on the ground that it secures a pure and uniform preparation. Many years ago the same plan was proposed by Dr. Hare.

The *Dublin* process proceeds on the same principle as the Edinburgh; namely, that of forming hyponitrous ether, and diluting this with alcohol. But the dilution is carried to a much greater extent; four fluidounces of the ether being mixed with forty-two fluidounces of alcohol, or in the proportion of one to ten and a half. This dilution makes it a little less than two-fifths as strong in hyponitrous ether as the Edinburgh preparation. The sp. gr. of sweet spirit of nitre is not given by the Dublin College; but it may be presumed that the dilution ordered by the College makes it conform in density to the London spirit.

Theory of the Production of Hyponitrous Ether, &c. One eq. of nitric acid, by reacting with one eq. of alcohol, forms one eq. of hyponitrous acid, one eq. of *aldehyd* ($C_4H_4O_2$), and two eqs. of water. Thus NO_5 and $C_4H_6O_2 = NO_3$ and $C_4H_4O_2$ and 2HO. The hyponitrous acid, as soon as formed, reacts with a second eq. of alcohol, so as to form one eq. of hyponitrous ether, with separation of one eq. of water. It has, however, been shown by Dr. Golding Bird that, when an excess of alcohol is used, *oxalhydric* (*saccharic*) acid is first formed, and that, when the formation of the hyponitrous ether has nearly ceased, aldehyd appears in the distilled product, and simultaneously oxalic acid in the contents of the retort, before which time the latter cannot be discovered. All these products result from the oxidizing action of the nitric acid upon the alcohol, increasing the proportion of oxygen in the substances formed, either by removing the hydrogen, or by abstracting this element and adding oxygen at the same time. The reader who may wish to pursue this subject, is referred to an interesting paper by Dr. Bird, in the *Lond. and Ed. Philos. Mag.*, xiv. 324, for May, 1839.

Properties of Hyponitrous Ether. *Pure* hyponitrous ether is pale-yellow, has the smell of apples and Hungary wines, boils at 62° (below 65° Hare), and has the sp. gr. 0·947 at 60°. The density of its vapour is 2·627. Litmus is not affected by it. When it is mixed with an alcoholic solution of potassa, hyponitrite of potassa and alcohol are formed, without producing a brown colour, showing the absence of aldehyd. It is soluble in 48 parts of water, and in all proportions in alcohol or rectified spirit. It is highly inflammable, and burns with a white flame without residue. The *impure* ether, as obtained by the Edinburgh and Dublin processes for subsequent dilution to form sweet spirit of nitre, boils at 70°, and has the density of 0·886 at 40°. The specific gravity assigned to it by the Edinburgh College is 0·899. Mixed with an alcoholic solution of potassa, it becomes dark-brown, with production of *aldehyd resin.* (See *page* 14.) This discoloration shows the presence of aldehyd. When kept it becomes acid in a short time, as shown by litmus; and nitric oxide is given off, which often causes the bursting of the bottle. Its tendency to become acid is rendered greater by the action of the air, and depends on the absorption of oxygen by the aldehyd, which thereby becomes acetic acid. These facts show the propriety of preserving this ether in small, strong bottles, kept full and in a cool place. Hyponitrous ether consists of one eq. of hyponitrous acid and one of ether, and its formula is C_4H_5O,NO_3. It is, therefore, improperly called *nitrous* and *nitric*

ether. Considered as a salt its proper name would be *hyponitrite of ether*. In its pure or concentrated state it is never used in medicine.

Properties of Spirit of Nitric Ether. This is a colourless volatile liquid, of a fragrant ethereal odour, and pungent, aromatic, sweetish, acidulous taste. It slightly reddens litmus, and does not effervesce with carbonate of soda. The Edinburgh preparation is yellow, and contains twenty per cent. of hyponitrous ether. Its officinal sp. gr. is 0·834 *U. S., Lond.;* 0·847 *Ed.* High density is not necessarily an index of deficient strength; as it may arise, as in the Edinburgh preparation, from containing a large proportion of hyponitrous ether. When heated by means of a water-bath, the U. S. sweet spirit of nitre begins to boil at 160°. It mixes with water and alcohol in all proportions. It is very inflammable, and burns with a whitish flame.

Impurities and Tests. Sweet spirit of nitre, when the product of a distillation too long continued, at first contains aldehyd, which afterwards becomes acetic acid by the absorption of oxygen—rapidly if the preparation be insecurely kept. The presence of aldehyd may be detected by its imparting a pungent odour and acrid flavour, and by the preparation containing it assuming a yellow tint on the addition of a weak solution of potassa, owing to the formation of aldehyd resin. Another test for aldehyd is the addition of an equal volume of sulphuric acid to the sweet spirit of nitre. If the sample be good, the change of colour will be slight, and the mixture will become considerably viscid; but if it contain much aldehyd, it will become dark-coloured. If water or spirit be present in undue proportion, the viscidity will be less. (*Phillips.*) As aldehyd appears to be the chief source of impurity in sweet spirit of nitre, and as it is detected by producing a characteristic colour with a solution of potassa, it would seem easy to make this test available as an index when the distillation should be discontinued. For if the distilled product were made to pass through a small portion of this alkaline solution, it would probably give indications of the first appearance of aldehyd, and thus enable the operator to stop the distillation in time. Acetic acid, as well as other acids (usually nitrogen acids) that may happen to be present, may be discovered by the taste, by their acting on litmus strongly, and by their decomposing the alkaline carbonates or bicarbonates with effervescence. These acids often operate injuriously by their chemical reactions with other substances, when associated in mixtures. Thus they liberate iodine from iodide of potassium, gradually decolorize compound infusion of roses, and, in the compound mixture of iron, hasten the conversion of the protoxide into the sesquioxide of iron. To obviate these effects, Mr. Harvey, of Leeds, keeps the sweet spirit of nitre standing on crystals of bicarbonate of potassa, and states that, if the preparation be of full strength, no appreciable portion of the alkali will be dissolved. (*Pharm. Journ. and Trans.*, Jan. 1842.) When acid sweet spirit of nitre is rectified from calcined magnesia, it becomes acid again in a short time; but, according to M. Klauer, when rectified from neutral tartrate of potassa, it continues unchanged for months. The rationale of the action of this salt, however, is not obvious. A deep-olive colour being produced with the sulphate of protoxide of iron, shows the presence of a nitrogen oxide or acid, and a blue tint with tincture of guaiac, passing through various shades of green, a nitrogen acid.

According to Mr. Bastick, sweet spirit of nitre contains about one-fifth of one per cent. of anhydrous hydrocyanic acid, when made from hyponitrous ether, formed by impregnating alcohol with hyponitrous acid, evolved by the action of nitric acid on starch, according to the process of Liebig. The same contaminating acid has been detected by M. Dalpaiz, in the preparation made according to the London Pharmacopœia, though not found in it by Mr. Bastick.

Alcohol and water are often fraudulently added to sweet spirit of nitre. When in undue proportion, they may be detected in the Edinburgh preparation, as

stated by the College, by agitating it with twice its volume of a concentrated solution of chloride of calcium. If the sweet spirit of nitre be of the full strength of this College, twelve per cent. of ether will slowly separate; showing that the chloride of calcium has taken up eight per cent., together with eighty per cent. of alcohol and water. If less ether separates, it shows the presence of too much alcohol and water. This test is hardly applicable to the U. S., London, and Dublin preparations, which are much weaker than the Edinburgh. Dr. Christison states that the London sweet spirit of nitre, when subjected to it, has never yielded in his trials more than four per cent. of ether. But it must be recollected that, when it yields by this treatment four per cent., it really contains twelve per cent.; for eight per cent. has been absorbed by the chloride of calcium test. Specific gravity is no criterion of the goodness of the preparation as obtained by any formula. The addition of water will raise its density; and so will the addition of hyponitrous ether. A high density, in connexion with deficient ethereal qualities, would, of course, show the presence of free acids, or an excess of water, or both. A specific gravity lower than the U. S. and London standard would probably indicate the presence of alcohol stronger than it should be, which might be either in proper amount or in too large proportion.

The fraudulent dilution of sweet spirit of nitre with alcohol and water is a great evil, considering the extensive use of the medicine, and its valuable remedial properties when pure. We have been informed, on good authority, that it is variously diluted with twice, thrice, and even four times its weight of alcohol and water. In some shops a strong and a weak preparation are kept, to suit the views of customers as to price. Some of the wholesale druggists are in the habit of diluting it, either upon the plea that the physician's prescriptions are written in view of the use of a weak preparation, or for the purpose of affording it at a low price. All these evils would be corrected, if the different manufacturing chemists in the Union would comply with the recommendation of the Philadelphia College of Pharmacy, and adopt for preparing it the formula of the United States Pharmacopœia. A uniform preparation being in this way furnished to the druggists, all that would be necessary on their part, would be to refrain from weakening it by the admixture of alcohol and water.

Medical Properties and Uses. Sweet spirit of nitre is diaphoretic, diuretic, and antispasmodic. It is deservedly much esteemed as a medicine, and is extensively employed in febrile affections, either alone, or in conjunction with tartar emetic, for the purpose of promoting the secretions, especially those of sweat and urine. It often proves a grateful stimulus to the stomach, relieving nausea and removing flatulence, and not unfrequently quiets restlessness and promotes sleep. On account of its tendency to the kidneys, it is often conjoined with other diuretics, such as squill, digitalis, acetate of potassa, nitre, &c., for the purpose of promoting their action in dropsical complaints. The late Dr. Duncan praised a combination of it with a small proportion of aromatic spirit of ammonia, as eminently diaphoretic and diuretic, and well suited to certain states of febrile disease. The dose is about a teaspoonful, given every two or three hours in a portion of water. When used as a diuretic, it should be given in larger doses.

CHLOROFORMUM. *U. S., Dub.* CHLOROFORMYL. *Lond. Chloroform. Terchloride of Formyle.*

"Take of Chlorinated Lime *ten pounds;* Water *three gallons and a half;* Alcohol *two pints.* Mix the Chlorinated Lime first with the Water, and then with the Alcohol, in a distillatory vessel having the capacity of about six gallons. Distil with a brisk heat into a refrigerated receiver, and, when the temperature approaches to 176°, withdraw the fire, in order that the distillation may proceed by the heat derived solely from the reaction of the materials. When the dis-

tillation slackens, hasten it by a fresh application of heat, and continue to distil until the liquid ceases to come over with a sweet taste. Separate the heavier layer of liquid in the receiver from the lighter by decantation, and, having washed it first with water, and then with a weak solution of carbonate of soda, agitate it thoroughly with powdered chloride of calcium, and distil it off by means of a water-bath, stopping the distillation when eleven-twelfths of the liquid have come over. The residue, together with the light liquid of the first distillation, may be reserved for use in a second operation." *U. S.*

"Take of Chlorinated Lime *four pounds;* Rectified Spirit *half a pint* [Imp. meas.]; Water *ten pints* [Imp. meas.]; Chloride of Calcium, broken into pieces, *a drachm.* Put the Chlorinated Lime, previously mixed with the Water, in a retort, and add the Spirit, the retort being of such a size as to be only one-third filled. Heat by means of a sand-bath, and so soon as ebullition begins, quickly withdraw the fire, that the retort may not break from a sudden increase of heat. Distil the liquor into a receiver until nothing comes over, renewing the fire if necessary. To the distilled liquor add four parts of water, and shake the whole well together. Separate carefully the heavier part which subsides, and add to it the Chloride of Calcium, shaking occasionally during an hour. Lastly, again distil the liquor from a glass retort into a glass receiver." *Lond.*

"Take of Chlorinated Lime *ten pounds* [avoirdupois]; Fresh-burned Lime *five pounds* [avoird.]; Water *four gallons* [Imp. meas.]; Rectified Spirit *twenty-five ounces* [avoird.]; Peroxide of Manganese, in fine powder, *two drachms* [Dublin weight]. Slake the lime with two pints [Imp. meas.] of the water, first raised to the boiling temperature, and, having placed the slaked Lime and Chlorinated Lime in a sheet iron or copper still, pour on the residue of the Water first mixed with the Spirit, and raised to the temperature of 100°. Connect now the still with a condenser, and apply heat, which, however, must be withdrawn the moment the distillation commences. The distilled product, the bulk of which need not exceed two pints [Imp. meas.], will occur in two distinct strata, the lower of which is the crude chloroform. Let this be agitated, twice in succession, with an equal volume of distilled water, and then, in a separate bottle, with half its volume of pure sulphuric acid. Lastly, let it be shaken in a matrass with the Peroxide of Manganese, and rectified from off this at a very gentle heat. The lighter liquid which distils over with the chloroform, and the water used in washing the latter, should be preserved with the view of their being introduced, with a new charge, into the still in a subsequent process. The specific gravity of Chloroform is 1·496." *Dub.*

In these processes, by the reaction of the chlorinated lime with the alcohol, chloroform is generated under the influence of a moderate heat. By a calculation it will be found that, while for ten pounds of chlorinated lime, the U. S. formula calls for thirty-two fluidounces of alcohol, the London and Dublin Colleges take about twenty-three and a half fluidounces. The water varies in the different formulæ from twenty-eight (*U. S.*) to thirty-two pints (*Dub.*). The chloroform, as first distilled, is found as a dense yellow layer, forming the lower portion of the distillate, and is quite impure. In order to purify it, the U. S. Pharmacopœia directs it to be washed with water to separate alcohol, agitated with a weak solution of carbonate of soda to remove chlorine, and rectified by distillation from chloride of calcium to free it from water. This distillation is stopped when eleven-twelfths of the liquid have come over, to avoid contaminating the product with a chlorinated pyrogenous oil, the presence of which interferes with the favourable action of the chloroform when inhaled. The same measures of purification, except the use of carbonate of soda, are directed by the London College. The Dublin College uses slaked lime, mixed with the chlorinated lime in the distillation, and purifies the crude chloroform by means of

water, sulphuric acid, and deutoxide of manganese. The object of the slaked lime is probably to lessen the production of the chlorinated pyrogenous oil, the amount of which is greater, according to Soubeiran and Mialhe, in proportion to the relative excess of the chlorine to the lime employed. The crude product, after having been freed from alcohol by washing with water in the usual way, is purified from the oil by agitation with half its volume of sulphuric acid, which must be *pure* and *colourless*, and at least of the density 1·840. The oil is charred and destroyed by the acid, which becomes yellow or reddish-brown, and partially changed into sulphurous acid. To remove the latter acid, agitation with deutoxide of manganese is directed, according to the plan of Mr. Alexander Kemp, of Edinburgh. The process of the Dublin College is the one proposed by Gregory and Kemp, of Edinburgh. According to these chemists chloroform is effectually purified from the pyrogenous oil by agitation with strong and pure sulphuric acid. So long as a ring, darker than the rest of the acid, appears, after rest, at the line of contact between the acid and the chloroform, the agitation must be repeated; and the oil is known to be fully separated, when the acid remains colourless. The same chemists deem it unnecessary to distil the chloroform from deutoxide of manganese to separate sulphurous acid; but consider agitation with the oxide as quite sufficient for this purpose, to be continued until the odour of the acid is replaced by the agreeable smell of pure chloroform. When chloroform is purified by manganese, it is apt to become, after the lapse of a few weeks, of a delicate pink colour, which sometimes disappears and then returns. This coloration depends upon the presence of manganese, and forms an objection to the use of the deutoxide as a purifier.

Dr. Gregory strongly recommends the above described process for purifying commercial chloroform as easily performed, and asserts that all good manufacturers purify it by the action of sulphuric acid. Nevertheless it has been shown that chloroform, thus purified, though apparently pure at first, will not keep, but, after the lapse of some time, becomes so loaded with chlorine that it cannot be inhaled. It appears from the observations of Dr. Christison that chloroform, purified by sulphuric acid containing nitrous acid, changes in less than twenty-four hours; but even when purified with pure acid, the decomposition begins at last, so that at the end of four weeks the odour of chlorine is intolerable. Whether chloroform, purified by chemically pure sulphuric acid, would undergo change, is not, perhaps, fully decided; but, for practical purposes, the purification by the repeated use of sulphuric acid must be abandoned. The manufacturers in Edinburgh have laid the process aside, and have recalled from their customers the chloroform which had been manufactured by it. In July, 1850, Mr. John Abraham pointed out the impurity of chlorine and muriatic acid in specimens of Edinburgh chloroform, no doubt manufactured by Dr. Gregory's process. These specimens had a suffocating odour, first reddened and then bleached litmus paper, and deposited on the inside of the bottle a greenish, oily-looking substance. Prof. Procter (in Oct. 1850) obtained some chloroform from a Philadelphia manufacturer, which presented similar defects, and was ascertained to have been made by the sulphuric acid process.

Chloroform may be made by the action of chlorinated lime on pyroxylic spirit (wood spirit); but when thus prepared it is largely contaminated with a chlorinated pyrogenous oil, analogous to that already mentioned as being found in smaller proportion in chloroform prepared from alcohol. Chloroform, thus prepared, conveniently called *methylic chloroform*, is purified with too much difficulty to be advantageously substituted for that made with alcohol, called by Soubeiran, *normal chloroform*. Chloroform may also be procured by distilling one part of oil of turpentine with eight parts of chlorinated lime and twenty-four of water. (J. Chautard, *Chem. Gaz.*, Feb. 1852, p. 68.)

Messrs. Duncan and Flockhart, druggists, of Edinburgh, manufacture chloroform on a large scale, in a peculiar apparatus, using the proportions of 20 parts of chlorinated lime, about 3¾ parts of rectified spirit, and 60 parts of water. They employ two large wooden barrels as a still, and a third as a receiver, and into the former throw steam, which furnishes both sufficient heat and water for the process. Sixty pounds of chlorinated lime are used by them at each distillation; and they are able to manufacture three hundred ounces of chloroform a day. The heavy layer of the distillate, constituting the impure chloroform, is purified by them, by mixing it with half its measure of strong sulphuric acid, gradually added, and distilling the mixture, when cool, in a leaden retort, from as much carbonate of baryta by weight, as of acid previously used by measure. The product is finally distilled from quicklime, after having stood over the earth, and been repeatedly shaken with it, for a day or two. In this long-tried process sulphuric acid is used; but it may be presumed that the chloroform made by it is not liable to undergo the change which follows the use of Gregory's process. It will be observed that the product, after the action of the sulphuric acid, is successively distilled from baryta and lime, thus removing all traces of the acid, to the presence of which, combined in some unknown way, the liability to change of chloroform, prepared by Gregory's process, may be plausibly attributed.

Discovery and History. Chloroform was discovered by Mr. Samuel Guthrie, of Sackett's Harbor, N. Y., in 1831, and about the same time by Soubeiran in France, and Liebig in Germany. Guthrie obtained it by distilling a gallon from a mixture of three pounds of chlorinated lime and two gallons of alcohol of the sp. gr. 0·844, and rectifying the product by redistillation, first from a great excess of chlorinated lime, and afterwards from carbonate of potassa. (*Silliman's Journal*, vol. xxi., Jan. 1832, p. 64.) In a subsequent letter to Professor Silliman, dated Feb. 15th, 1832, Mr. Guthrie states that the substance which he had obtained, "distilled off sulphuric acid, has the specific gravity of 1·486, or a little greater, and may then be regarded as free from alcohol; and if a little sulphuric acid which sometimes contaminates it be removed by washing it with a strong solution of carbonate of potassa, it may then be regarded as *absolutely pure.*" (*Ibid.*, vol. xxii., July 1832, p. 105.) It is thus evident that Mr. Guthrie obtained in a pure state, the substance now called chloroform; but he erroneously supposed his product to be the well-known oily liquid of the Dutch chemists, which it greatly resembles, and for the preparation of which he believed he had fallen on a cheap and easy process. Under this impression, he calls the substance, in his communications, *chloric ether*, one of the names by which the *Dutch liquid*, or *chloride of olefiant gas*, is designated. He was induced to make the preparation from noticing a passage in Professor Silliman's Elements of Chemistry, which referred to the Dutch liquid as a grateful diffusible stimulant, when properly diluted with alcohol and water. In relation to the anticipated importance of this substance as a medicine, Mr. Daniel B. Smith, President of the Philadelphia College of Pharmacy, holds the following language in July, 1832. "The action of this ether on the living system is interesting, and may hereafter render it an object of importance in commerce. Its flavour is delicious, and its intoxicating qualities equal to or surpassing those of alcohol. It is a strong diffusible stimulus, similar to the hydrated ether, but more grateful to the taste." (*Journ. of the Phil. Col. of Pharm.*, iv. 118.)

Properties. Chloroform is a limpid, colourless, volatile, neuter liquid, having a bland ethereal odour, and hot, aromatic, saccharine taste. It neither reddens nor bleaches litmus paper. It is but slightly soluble in water. Its sp. gr. is 1·49 *U. S.*, 1·48 *London*, and 1·496 *Dub.* Gregory has obtained it of the density 1·5 at 60°. It boils at 142°. It is not inflammable, but renders the flame of an alcohol lamp yellow and fuliginous. It burns, however, with a smoky

flame, when mixed with an equal volume of alcohol. When pure, it has no action on potassium. According to M. Augendre and M. Ed. Robin, chloroform is a powerful antiseptic. It does not, like creasote, coagulate albumen. It is scarcely acted on by sulphuric acid in the cold, but dissolves readily in alcohol and ether. The alcoholic solution, when moderately diluted with water, forms an aromatic, saccharine liquid of a very grateful taste. A strong alcoholic solution is decomposed by abundance of water, the chloroform separating and subsiding, and the alcohol uniting with the water. Chloroform has extensive solvent powers, being capable of dissolving caoutchouc, gutta percha, mastic, elemi, tolu, benzoin, and copal. Amber, sandarac, lac, and wax are only partially soluble. It also dissolves iodine, bromine, the organic alkalies, fixed and volatile oils, most resins, and fats. It dissolves sulphur and phosphorus sparingly. It possesses the power of dissolving a large quantity of camphor, and furnishes the means of administering that medicine in an elegant form. As a general solvent, it has the advantage over ether of not being inflammable; the inflammability of the latter being the cause of frequent accidents. For an extensive list of substances, soluble, insoluble, and partially soluble in chloroform, see a paper by M. Lepage, of Gisors, France, copied into the *Am. Journ. of Pharm.* for April, 1852, p. 147.

Composition. Chloroform is composed of three eqs. of chlorine and one of formyle, and is, therefore, the terchloride of formyle. As formyle is a bicarburet of hydrogen, the formula of chloroform is C_2HCl_3. Its composition was first accurately determined by Dumas in 1835, by whom it was called chloroform from its relation to formic acid (C_2HO_3), being formic acid with its three eqs. of oxygen replaced by three of chlorine. When first obtained by him, Liebig supposed it to consist exclusively of chlorine and carbon; and hence the origin of the erroneous name of *perchloride of carbon*, by which it is sometimes called.

The rationale of the formation of chloroform has not been well made out. If alcohol be considered a bihydrate of etherine C_4H_4+2HO, it may be presumed to be generated by the removal from the etherine of two eqs. of carbon, and the substitution of three eqs. of chlorine for three of hydrogen. Thus $C_4H_4-C_2H_3+Cl_3=C_2HCl_3$.

Impurities and Tests. Chloroform is liable to contain alcohol and ether, both of which lower its specific gravity. To determine the presence of impurity which has this effect on its density, Soubeiran recommends that a drop of the suspected chloroform be added to a mixture of equal weights of concentrated sulphuric acid and water. Such an acid, when cool, will have the specific gravity of 1·38, and good chloroform, being of greater density, will sink in it. Any specimen of chloroform which floats in this acid should be rejected as too light; but its sinking would not prove its density to be sufficiently high. M. Mialhe has proposed the following test for the presence of alcohol. Drop into distilled water a small quantity of the chloroform. If pure, it remains transparent at the bottom of the glass; but, if it contain even a small proportion of alcohol, the globules acquire a milky appearance. The most injurious impurities are the chlorinated pyrogenous oils, already alluded to. These are different as obtained from methylic or normal chloroform. The oil obtained by Soubeiran and Mialhe from methylic chloroform, is an oleaginous, yellow liquid, lighter than water, and having a peculiar nauseous empyreumatic odour, perceptible in the methylic chloroform itself. In commercial chloroform it is sometimes present to the amount of six per cent. It is easily set on fire, and burns with a smoky flame, chlorine being among the products of its combustion. The oil procured from normal chloroform, which contains it only in the amount of about one-fifth of one per cent, is essentially different from the methylic chloroform oil. It is heavier than water, and has an acrid, penetrating odour, unlike that of the other

oil. When the vapour of these oils is inspired or even smelt, it causes, according to Dr. Gregory, distressing sickness and headache. These pyrogenous oils are detected by the action of *pure* and *strong* sulphuric acid. Pure chloroform, when mixed with an equal volume of the acid, does not colour it; but, when contaminated with these oils, gives the acid a colour, varying from yellow to reddish-brown, according to the amount of impurity present. In applying this test, several fluidounces of chloroform should be used; as a slight change of colour cannot be easily seen in a test tube. The discoloration of sulphuric acid by impure chloroform was first noticed by Mr. Morson, of London, in Nov. 1848. A still more delicate test of the oily impurities, according to Dr. Gregory, is the smell which they leave. If chloroform, thus contaminated, be poured upon the hand, it quickly evaporates, leaving the oily impurities, recognizable by their peculiar offensive smell, which is now no longer covered by that of the chloroform. The pure substance, rubbed upon the skin, quickly evaporates, and scarcely leaves any odour. (See the paper of Soubeiran and Mialhe, *Journ. de Pharm.*, July, 1849, copied into the *Am. Journ. of Pharm.*, xxi. 313. Also the paper of Dr. Gregory, *Chem. Gaz.*, May 15, 1850.) According to Mr. Henry Pemberton, of Philadelphia, the pyrogenous oils are not derived from the common whisky ordinarily employed in procuring chloroform; as he ascertained by making the preparation from pure alcohol of 92 per cent. (*Am. Journ. of Pharm.*, March, 1853, p. 113.)

Medical Properties, &c. When taken *internally*, chloroform acts as a sedative narcotic, probably operating through the nervous system, independently of vascular action or congestion. Nevertheless it has been detected by Ragsky in the blood, by distilling an ounce from a flask, furnished with a tube bent horizontally, and containing at its further extremity a strip of paper, coated by iodide of potassium and starch paste. A portion of the horizontal tube is heated to redness; and the volatilized chloroform, being decomposed as it passes along the tube, furnishes muriatic acid and chlorine, which, by coming in contact with the iodide and starch, develop iodine and strike a blue colour. The inside of the further extremity of the tube may be moistened with a solution of nitrate of silver, dispensing with the iodide and starch, according to the plan of Dr. Snow, in which case chloride of silver will be formed. Proceeding in a similar manner, Dr. Snow has proved that chloroform may be detected in different portions of the dead body destroyed by this agent.* Dr. H. Hartshorne, who tried its physiological effects in the dose of seventy-five drops on himself, found it to produce a general diminution of sensorial power, with drowsiness, and without exhilaration or acceleration of the pulse. (*Am. Journ. of Med. Sci.*, Oct. 1848, p. 353.) Since then he has used it internally in a number of cases, and finds it a safe anodyne and soporific remedy, altogether free from the dangerous effects which sometimes follow the inhalation of its vapour. In the dose of a fluidrachm, its soporific effect is about equal to that of thirty-five drops of laudanum. Dr. Hartshorne has given it in doses of from fifty to seventy-five drops every half hour for several hours together. The best vehicle is orgeat syrup, in the proportion of two fluidounces to each fluidrachm of the chloroform. When mixed with mucilage of gum Arabic, the mixture requires agitation, immediately before swallowing each dose. (*Ibid.*, Jan. 1854, p. 113.) Chloroform, as prepared by Mr. Guthrie, was used internally as early as 1832 by Professor Ives, and Dr. Nathan B. Ives, of New Haven, in asthma, spasmodic cough, scarlet fever, and atonic quinsy, with favourable results. (*Silliman's Journ.*, xxi. 406, 407.) It was employed by Dr. Formby, of Liverpool, in hysteria, in 1838; by Mr. Tuson,

* In relation to the detection of chloroform in dead bodies, see the paper of M. Duroy, of Paris, in the *Journ. de Pharm.*, Avril, 1851.

of London, in cancer and neuralgic affections, in 1843; and by M. Guillot, of Paris, in asthma, in 1844. Antiperiodic properties have been attributed to it by Dr. Delioux, of Rochefort, who proposes it as a remedy in intermittents, given, during the apyrexia, in cases in which the bark and quinia fail to effect a cure. Dr. Aran has employed it with success in lead colic, administered by the mouth and rectum, and applied to the abdomen. In these cases it probably acts by relaxing the intestinal spasm. One of the authors of this work has frequently used it with advantage for the relief of neuralgic and other painful affections, in the dose of from forty to eighty drops, suspended in water by means of gum Arabic or yolk of egg. This dose may be repeated, if necessary, at intervals of one or two hours, until some effect on the system is produced. A disadvantage connected with the internal use of chloroform is its liability to sicken the stomach, an effect which may sometimes arise from the presence of pyrogenous oil as an impurity. *Externally*, it was used, in 1843, by Mr. Tuson, in cancer, senile gangrene, and sloughing ulcers, and, in the form of injection and gargle, in profuse discharges from the uterus, and foul ulcers of the throat, with the effect of relieving pain, destroying fetor, and promoting the separation of diseased parts. It has also been employed externally with benefit by an anonymous writer in the *Boston Medical and Surgical Journal*, in a painful wound of the forearm, implicating the radial nerve; by Dr. Legroux in a painful affection of one of the lower extremities, consequent to a cancerous tumour of the pelvis; by Mr. Higginson in labour, applied to the perineum when painfully stretched, and in dysmenorrhœa, brought in contact with the os uteri by means of a sponge; by Dr. Watson in swelled testicle and acute spinal tenderness; by Dr. Hays and Dr. Bond in neuralgia; by the late Dr. I. Parrish in the supra-orbitar pain of rheumatic ophthalmia, and in syphilitic ulceration at the root of the nail; and by M. Devergie in papulous eruptions, made into an ointment in the proportion of a fluidrachm to ten drachms of lard. It has also been used with success by Dr. Venat, of Bordeaux, in the form of injection, in the commencement of acute gonorrhœa, as an abortive treatment. Mr. Behrend, of Liverpool, recommends it in all stages of this complaint, injected pure, or mixed with mucilage. This treatment gives great pain, and is, moreover, hazardous. Dr. Rauch, of Iowa, has employed chloroform topically with decided benefit in neuralgia, colic, and other painful affections. For some purposes he found it useful to incorporate it with olive oil and solution of ammonia, which formed a mixture having effects less transient than those of the uncombined chloroform. (*Am. Journ. of Med. Sci.*, July, 1851, p. 112.) As a wash, injection, and gargle, Mr. Tuson prepared it diluted with water, in the proportion of one or two drachms to the pint; but, as an application to the sound skin, it is generally used undiluted, by means of lint or soft rags, covered with oiled silk to prevent evaporation. When employed undiluted it should be pure; as, according to M. Mialhe, when it contains absolute alcohol, it acquires caustic properties.

A third method of using chloroform is by *inhalation*. The first case we have met with in which it was employed in this way, is related by Professor Ives, of New Haven, under date the 2d of Jan. 1832. The case was one of pulmonic disease, attended with general debility and difficult respiration, and was effectually relieved. (*Silliman's Journ.*, vol. xxi., Jan. 1832, p. 406.) In March, 1847, the action of the pure substance by inhalation was tried on the lower animals by M. Flourens, and its effects on the spinal marrow described. In November of the same year, Dr. Simpson, of Edinburgh, after experimenting with a number of anæsthetic agents, in order to discover a substitute for ether, tried chloroform at the suggestion of Mr. Waldie, and, having found its effects favourable, brought it forward as a new remedy for pain, by inhalation, in surgery and midwifery. The advantages which he conceives it to possess over ether, are the small-

ness of its dose, its more prompt action, its more agreeable effects, its less tenacious odour, its greater cheapness, and the readiness with which it may be exhibited.

The usual effects produced by a full dose of chloroform, administered by inhalation, are the rapid production of coma, relaxation of the muscles, slow and often stertorous breathing, upturning of the eyes, and total insensibility to agents which ordinarily produce acute pain. The effect on the heart's action is variable. Sometimes frothing of the mouth takes place, and, more rarely, convulsive twitches of the face and limbs. The insensibility is generally produced in one or two minutes, and usually continues for five or ten minutes; but the effect may be kept up for many hours, provided the inhalation be cautiously renewed from time to time. The immediate effects of the agent are followed by a drowsy state, sometimes by quiet sleep. As a general rule, no recollection is retained of anything that occurred during the state of insensibility. Experience has shown that the effects, here described as those of a full dose of chloroform by inhalation, cannot be induced without danger to life. Hence all prudent surgeons will be content with an impression short of the abolition of all consciousness. It is generally admitted that, at a certain stage of anæsthesia, there is insensibility to pain, while consciousness to a certain extent remains; and it is this condition that the surgeon should aim to produce. According to Mr. Skey, chloroform has been administered in 9000 cases in St. Bartholomew's Hospital, without a single accident, a fact which must be taken as proof of its careful and skilful employment in that institution. (See *Am. Journ. of Med. Sci.*, April, 1851, p. 498.) It is asserted to be an advantage of chloroform in surgical operations, that less blood is lost. If this assertion should prove true, there will be greater necessity of delaying the dressings until reaction has taken place.

The relative advantages and disadvantages of chloroform, when compared with ether as an anæsthetic in operative surgery, have not been satisfactorily determined; but on one point the evidence appears to be conclusive, namely, that it is far more dangerous to life than ether. According to Dr. Snow, of London, the vapour in the air breathed by the patient should not exceed six per cent. When thus used, insensibility is slowly and safely induced. (*London Med. Times*, Nov. 1853, p. 485.) Dr. Gilman, of New York, thinks that chloroform has a more sudden and powerful effect than under ordinary circumstances, when inhaled immediately after bleeding; a fact which he explains by the increased power of absorption produced by the loss of blood. (*N. Y. Med. Times*, Oct. 1852.)

In midwifery, chloroform has been extensively employed to relieve pain and facilitate labour, since it was first recommended by Dr. Simpson. Its effects in subduing the pain of childbearing are similar to those of ether; and each agent has its exclusive advocates among those practitioners of midwifery who are willing to use anæsthetics. The remarks, made in relation to ether used in labour, are applicable for the most part to chloroform, and, therefore, need not be repeated here. (See *page* 831.)

The dose of chloroform for inhalation is a fluidrachm, equivalent to 220 drops or more, to be repeated in two minutes, if the desired effect should fail to be produced. The most convenient inhaler is a handkerchief, loosely twisted into the form of a bird's nest, which, after having been imbued with the chloroform, is held to the mouth and nose. The use of this simple inhaler insures a due admixture of atmospheric air with the vapour of the chloroform. The moment insensibility is produced, the inhalation should be suspended; and, if consciousness return too soon, it should be cautiously renewed. It is a good rule not to administer chloroform to persons subject to epilepsy, affected with organic disease of the heart, or predisposed to cerebral congestion. For the rules laid down by M. Baudens for the administration of chloroform, see the *Am. Journ. of Med. Sci.* for Jan. 1854, p. 208.

Chloroform, as ordinarily prepared, is apt to produce, when inhaled, headache, nausea, and even vomiting. Perfectly pure chloroform, according to Soubeiran and Mialhe, does not produce these disagreeable effects, which are plausibly attributed to the presence of the pyrogenous oils. Dr. Simpson, however, finds that the purest chloroform that he uses not unfrequently causes vomiting; but Dr. Gregory attributes this effect, when following the use of the pure substance, to its administration after a full meal, which should always be avoided.

Chloroform has been recently used in Paris (Feb. 1854), with alleged success, by Dr. Delabarre, for producing local anæsthesia before surgical operations, without affecting the general system.

Chloroform having proved to be a relaxing agent and remedy for pain, when used by inhalation in surgery and midwifery, it was natural that its effects should be tried in the same way in spasmodic and painful affections. Accordingly, it has been inhaled in hiccough, hooping-cough, hysteria, the paroxysm of asthma, angina pectoris, nephritic colic, tetanus, poisoning from strychnia, hydrophobia, and the paroxysm of tic douloureux, and generally with decided advantage. Several German physicians have recently (1853) praised it in pneumonia as an expectorant and calming remedy. It has been employed also with success for the reduction of strangulated hernia. Mr. R. J. Mackenzie, of Edinburgh, bears testimony to its good effects, used by inhalation, in spasmodic stricture of the urethra, attended with retention of urine. Sometimes the urine is caused to flow at once; and, when this is not the case, the passage of the catheter is facilitated. (See *Am. Journ. of Med. Sci.*, July, 1852, p. 250.) As a hypnotic it has been given beneficially in delirium tremens, and in the noisy forms of chronic insanity.

Much has been said in relation to the dangers attendant upon the inhalation of chloroform, and, certainly, many more deaths have been reported from its use than from that of ether. Dr. Warren, in 1849, gave the details of ten cases, in which death was caused by chloroform, all occurring in little more than a year, and many other fatal cases have since occurred; and he declares that, if he were compelled to substitute chloroform for ether in inhalation, he would do it with much anxiety. Chloroform is unquestionably a more powerful agent than ether, and acts not only differently, but in a much smaller dose. The comparative smallness of its dose is certainly a ground of danger, when its administration falls into reckless or incompetent hands. At the same time it must be borne in mind that a great number of persons have inhaled chloroform, either as patients, or with a view to its pleasurable effects.

When the effects of chloroform inhalation proceed too far, the proper remedies are the horizontal posture, cold air fanned upon the face, cold water poured upon the head, sinapisms to the feet, frictions and heat to the body and extremities, and ammonia to the nostrils. If these remedies fail, artificial respiration must be resorted to. When the patient can swallow, strong coffee may be given with advantage. Galvanic electricity, passed through needles inserted in different parts of the body, is recommended by M. Abeille, of Ajaccio, as a powerful means of recalling sensibility; and it is highly probable that the electro-magnetic battery would be found useful. When an over-dose is taken by the stomach, the same remedies may be employed, with the addition of the stomach-pump, when vomiting cannot be produced by alum or mustard. In a case of suicide by swallowing chloroform, in which death took place in about thirty-four hours, reported in the fifth volume of the *Edinburgh Journ. of Med. Science*, the lining membrane of the larynx and trachea was found inflamed, the bronchi were loaded with a dirty-gray purulent fluid, the lungs were inflamed as in the first stage of pneumonia, and the brain and its membranes congested.

A preparation for inhalation, composed of one-third pure chloroform and

two-thirds nearly absolute alcohol, has been recommended by Dr. Warren, under the name of *strong chloric ether*. As the name, chloric ether, was originally applied by Dr. T. Thomson to the Dutch liquid, or chloride of olefiant gas, it would be well to abandon the same appellation to designate either chloroform, or its union with alcohol. Correct names for the latter combination would be either *alcoholic solution of chloroform*, or *tincture of chloroform*. Dr. Warren has used his preparation in fifty cases with success, and considers it safer than chloroform, and more agreeable than ether. (*Warren on the Effects of Chloroform and of Strong Chloric Ether.* Boston, 1849.) Further observation is required to determine the value of "strong chloric ether" as an anæsthetic. The alcohol may prove useful by obviating, through its stimulant properties, the depressing influence of the chloroform; and ether has been occasionally given, in connexion with chloroform, with the same view.

The preparation, sold in London and elsewhere under the name of "chloric ether," is a weak tincture of chloroform of variable quality, containing at most but 16 or 18 per cent. of chloroform, and sometimes not more than 5 or 6 per cent. B.

COLLODIUM. *U. S. Collodion. Ethereal Solution of Gun Cotton. Maynard's Adhesive Liquid.*

"Take of Cotton, freed from impurities, and finely carded, *half an ounce;* Nitrate of Potassa, in powder, *ten ounces;* Sulphuric Acid *eight fluidounces and a half;* Ether *two pints and a half;* Alcohol *a fluidounce.* Add the Sulphuric Acid to the Nitrate of Potassa in a Wedgwood mortar, and triturate them until uniformly mixed; then add the Cotton, and, by means of the pestle and a glass rod, imbue it thoroughly with the mixture for four minutes. Transfer the Cotton to a vessel containing water, and wash it, in successive portions, by agitation and pressure, until the washings cease to have an acid taste, or to be precipitated on the addition of chloride of barium. Having separated the fibres by picking, dry the Cotton with a gentle heat, dissolve it by agitation in the Ether previously mixed with the Alcohol, and strain. Collodion should be kept in closely stopped bottles previously well dried." *U. S.*

Cotton is changed into a peculiar explosive substance, called gun cotton, by the action of nitric acid. (See *Gun Cotton* in the *Appendix.*) It is this substance, freshly prepared, which is dissolved in ether assisted by a little alcohol, to form collodion. Gun cotton may also be prepared by the process of Dr. Ellet, of South Carolina College, which consists in steeping the cotton in a mixture of nitre and sulphuric acid. This mixture sets free the necessary nitric acid for effecting the change in the cotton. As this process affords a gun cotton which readily dissolves in ether, while other processes furnish a product which sometimes dissolves only partially, at other times not at all, it has been selected in the U. S. Pharmacopœia for preparing the cotton for solution in the ether. Gun cotton, prepared by the above process, if well washed, is not liable to decomposition. Prof. Procter has kept it for a year, and found it still perfectly soluble in ether.

Collodion is a transparent, colourless liquid, of a syrupy consistence, and ethereal smell. When applied to a dry surface, the ether quickly evaporates, and a transparent film is left, having remarkable adhesiveness and contractility. On account of the great volatility of ether, collodion must be kept in bottles well stopped. When insecurely kept, the liquid thickens and becomes less fit for the use of the surgeon. The thickened liquid sometimes contains acicular crystals of gun cotton, as was first observed by Mr. Higginson, of London, and afterwards by Dr. J. Leidy, of this city, who examined collodion for crystalline bodies with the microscope at the suggestion of Mr. E. Parrish.

Collodion was first applied to the purposes of surgery by Mr. J. Parker Maynard, student of medicine, of Boston, in January, 1847. It is employed for holding together the edges of incised wounds, for covering ulcers or abraded surfaces with an impervious film, not acted upon by water, and for encasing parts which require to be kept without relative motion. It is applied alone, brushed over the part, or by means of strips of muslin. In whatever way applied, the solvent quickly evaporates, and leaves the solid adhesive material. According to Lepage, gun cotton will dissolve in equal parts of ether and alcohol, forming a solution quite as adhesive as that made with ether alone. As this solution dries more slowly, it may prove preferable to the ethereal solution in certain cases. The strong contractile power of the collodion coating is an objection to it for some purposes. This property is removed, according to Mr. C. S. Rand, of Philadelphia, by dissolving first one part of gun cotton, and then one part of Venice turpentine in twenty parts of ether. To give more flexibility to the film, M. Sourisseau, of Kaiserberg, adds one part of elemi to twelve of collodion. According to Mr. Startin, of London, opacity and elasticity may be imparted at the same time, by adding from half a drachm to a drachm of lard, or some similar fatty matter, previously dissolved in ether, to an ounce of collodion. The qualities of softness and elasticity are given by combining collodion with castor oil, in the proportion of thirty parts to two, agreeably to the plan of M. Guérsant, who found it useful, thus modified, in erysipelas. An elastic collodion, somewhat similar, in which, besides castor oil, Venice turpentine and white wax are added, has been proposed by E. Lauras. (*Pharm. Journ.*, xii. 303.) In order to imitate the colour of the skin, an ethereal tincture of turmeric or of saffron may be added, so as to produce the desired tint. Dr. Meller has proposed a solution of shell lac in highly rectified alcohol, so as to have a gelatinous consistence, as a succedaneum for collodion.

Collodion has been used with advantage by Dr. J. R. Mitchell, of Dublin, and by Dr. Aran, to form an artificial covering to ulcers of the os and cervix uteri, thereby allowing the healing process to go on underneath; by M. Wetzlar, of Aix-la-Chapelle, in chilblains; by M. Sourisseau, and by Dr. Liman, of Berlin, in burns; and by Dr. J. W. Freer, of Illinois, in erysipelas. According to Dr. Christen, of Prague, collodion is useful in erysipelas from local causes only, such as wounds, ulcers, burns, &c., but hurtful in the disease from an internal cause. The same writer condemns its use to prevent pitting in smallpox as positively injurious. In superficial inflammation it appears to act on the principle of the contractile power of the film, thus driving out the blood from the inflamed vessels; and it is in this way probably that it proves useful in erysipelas.

Mr. Erasmus Wilson has used collodion with decided advantage in certain diseases of the skin. It acts principally by furnishing a substitute for the epidermis, and by the local pressure which its contraction in drying produces. In chapped nipples it has an admirable effect. Dr. J. H. Claiborne has used a thick coating of collodion with decided advantage as a compressing agent for the discussion of buboes. When applied to ulcers, abrasions, or chaps of the skin, it requires to be diluted with ether, so as to render it nearly as limpid as water. Mr. J. H. Tucker found it useful in stopping the bleeding from leech-bites. M. Sourisseau and Mr. E. H. Durden have used it as a coating for pills, which are thereby deprived of taste, but not injured in medicinal properties.

Collodion has become an important agent in photography, in the preparation of crystallotypes. B.

ALCOHOL.

Preparations of Alcohol.

ALCOHOL AMYLICUM. *Dub. Fusel Oil. Grain Oil. Corn Spirit Oil. Potato Spirit Oil. Amylic Alcohol. Hydrated Oxide of Amyle.*

"Take of the light liquid, which may be obtained at any large distillery, by continuing the distillation for some time after the pure spirit has been drawn off, *any convenient quantity*. Introduce it into a small still or retort connected with a condenser, and apply heat so as to cause distillation. As soon as the oil begins to come over unmixed with water, the receiver should be changed, and the distillation being resumed and carried nearly to dryness, the desired product will be obtained. The liquid drawn over during the first part of the distillation will consist of an aqueous fluid, surmounted by a stratum of the Fusel Oil. This latter, though impregnated with a minute quantity of water, should be separated and preserved, as being sufficiently pure for use." *Dub.*

This oil is always present in the products of the alcoholic fermentation. It is an ingredient in the ardent spirit obtained from various grains, but is most abundant in that procured from fermented potatoes. In grain spirit it is present in the proportion of about one part in five hundred by measure. When grain or potato whisky is distilled for the purpose of obtaining alcohol, the pure spirit will continue to come over for a certain time, after which, if the distillation be continued, a milky liquid will be obtained, which, upon standing, will be covered with a stratum of this peculiar oil. Subjected to distillation, the milky liquid will at first boil at a comparatively low temperature, and yield water and a little of the oil; but after a time the boiling point will rise to 269°, when the oil will come over pure. By changing the receiver when the oil begins to distil free from water, the Dublin College collects the oil separate from the watery part. In relation to fusel oil, see a paper by Edward N. Kent, in the *N. Y. Journ. of Pharm.* (i. 257); and one by Dr. Charles M. Wetherill, copied into the *Am. Journ. of Pharm.* for Sept. 1853.

Properties. Fusel oil is an oily, colourless liquid, of a strong offensive odour, and acrid burning taste. As usually prepared it has a pale-yellow colour. Its sp. gr. is 0·818; that of its vapour 3·15. It boils at 269°, and congeals at −4°, in the form of crystalline leaves. It is very sparingly soluble in water, but unites in all proportions with alcohol and ether. It dissolves iodine, sulphur, and phosphorus, and forms a good solvent for fats, resins, and camphor. When dropped upon paper it does not leave a greasy stain. It does not take fire like alcohol by the contact of flame, but requires to be heated to a temperature of about 130° before it begins to burn. Experiments on inferior animals show it to be an active irritant poison. It consists of ten eqs. of carbon 60, twelve of hydrogen 12, and two of oxygen 16=88. It is generally considered to be a hydrated oxide of a compound radical called *amyle* ($C_{10}H_{11}$); and on this view its formula will be $C_{10}H_{11},O+HO$. When subjected to oxidizing agents, it loses two eqs. of hydrogen and gains two of oxygen, and becomes $C_{10}H_9,O_3+HO$, or *amylic acid*, which is identical with *valerianic acid*, the acid found in valerian. This acid bears the same relation to fusel oil that acetic acid does to wine alcohol, and formic acid to methylic alcohol. Amyle has been isolated by Dr. E. Frankland. It is a colourless pellucid liquid, of the sp. gr. 0·7704. (*Chem. Gaz.*, March 15, 1850.)

Crude fusel oil may be obtained from the alcohol distillers. According to Mr. Kent, of New York, it contains, as impurities, water, alcohol, acetic and valerianic acid, oxide of iron, and an amyle compound, analogous to œnanthic ether.

Fusel oil was made officinal by the Dublin College, in its Pharmacopœia of 1850, as an artificial source of valerianic acid, to be used in forming valerianate of soda, from which, by double decomposition, three other valerianates, namely, those of iron, zinc, and quinia, are directed to be formed by the College.

Off. Prep. Sodæ Valerianas. B.

SPIRITUS FORTIOR. *Dub.* *Stronger Spirit.*

"Take of Rectified Spirit *half a gallon* [Imp. meas.]; Carbonate of Potash from Pearlash *eight ounces* [avoirdupois]. Having dried the Carbonate of Potash at a low red heat, and rapidly reduced it to powder in a warm mortar, let it be shaken occasionally for four hours in a bottle with the Spirit, maintaining the temperature of the mixture at or about 100°. After a subsidence of twenty minutes' duration, the liquid will form two distinct strata, the uppermost of which (measuring about seventy-four ounces) should be separated by decantation or a syphon, and then distilled with the aid of a Liebig's condenser, and chloride of zinc bath, until the product amounts to seventy-two ounces. The specific gravity of this spirit is 0·818." *Dub.*

In this newly introduced formula of the Dublin College, rectified spirit (sp. gr. 0·840) is shaken with hot and dry carbonate of potassa, to separate water; and the strengthened spirit, floating over the more aqueous portion, which forms the solvent of the added carbonate, is decanted, and distilled with a heat regulated by a chloride of zinc bath, until $\frac{3}{4}\frac{6}{7}$ths have passed over.

Stronger spirit has the same general properties as alcohol, described at *page* 61 as the type of a class, including its varieties of different strengths. Agreeably to the density assigned to it by the Dublin College (0·818), it contains between eight and nine per cent. of water. It is used by the Dublin College in preparing several essences, and in making absolute alcohol. (See *next article.*)

Off. Prep. Alcohol, *Dub.*; Essentia Menthæ Piperitæ; Essentia Menthæ Viridis; Essentia Myristicæ Moschatæ. B.

ALCOHOL. *Ed.*, *Dub.* *Absolute Alcohol.*

"Take of Rectified Spirit *one pint* [Imp. meas.]; Lime *eighteen ounces*. Break down the Lime into small fragments; expose the Spirit and Lime together to a gentle heat in a glass matrass till the Lime begins to slake; withdraw the heat till the slaking is finished, preserving the upper part of the matrass cool with damp cloths. Then attach a proper refrigeratory, and with a gradually increasing heat distil off seventeen fluidounces [Imp. meas.]. The density of this alcohol should not exceed 0·796; if higher, the distillation must have been begun before the slaking of the Lime was finished." *Ed.*

"Take of Stronger Spirit *one pint* [Imp. meas.]; pulverized fresh-burned Lime *ten ounces* [avoirdupois]. Having introduced the Lime and Spirit into a matrass, connected in the usual manner with a Liebig's condenser, let heat be applied until the lime begins to slake, and when this process is completed, distil by means of a chloride of zinc bath until the liquid which comes over, together with that obtained during the slaking, measures two ounces [Imp. meas.]. This being rejected, the receiver should be changed, and the distillation resumed, and continued until a product of nearly sixteen ounces [Imp. meas.] is procured. The specific gravity of this product is 0·795." *Dub.*

In these processes an alcoholic liquid of a given specific gravity is brought to its highest strength, so as to form absolute alcohol, by the dehydrating action of lime, and subsequent distillation. These processes are good ones, and, if carefully followed, will yield absolute alcohol. Dr. Christison assures us, that, on using pure quicklime, with the precautions mentioned in the Edinburgh formula, he has "always obtained from rectified spirit of the density of 0·838, seventeen-twentieths of its volume of alcohol, of density 0·796; and if the first tenth be kept apart, the rest may be obtained so low as 0·7942."

Soubeiran recommends the following as an easy method for obtaining alcohol free from water, abundantly and economically. 1st. Rectify alcohol, marking 86° of the centesimal alcoholmeter of Gay-Lussac (rectified spirit), by distilling it from carbonate of potassa. This operation raises its strength to 94° or 95°. 2d. Raise this alcohol to 97°, by distilling it with fused chloride of calcium, or by digesting it with quicklime (from which it must be afterwards poured off), in the proportion of a pint of the alcohol to 1½ ounces of the chloride, or 2¼ ounces of the lime. 3d. Distil the product of this operation slowly with quicklime, in the proportion of 3¾ ounces to the pint. The product will be absolute alcohol. The operation may be shortened to two steps, by distilling the alcohol of 94° or 95°, with an excess of quicklime (7½ ounces to the pint). In all cases, before decanting or distilling, the alcohol must be digested for two or three days with the lime, at a temperature between 95° and 100° F. Lime will not answer as a substance to be distilled from, unless it be in sufficient excess; for otherwise, towards the end of the distillation, the hydrate of lime formed will yield up its water to the alcohol, and weaken the distilled product. (*Journ. de Pharm.*, xxv. 1, Jan. 1839.) Thus it appears that the Edinburgh and Dublin processes for absolute alcohol are substantially the same as the short process of Soubeiran.

Properties. Absolute alcohol is a colourless, volatile liquid, of an agreeable odour and burning taste. It boils at 172°, and is not congealed by a cold of 166° below zero. Its officinal density is 0·794–6 *Ed.;* 0·795 *Dub.* Its sp. gr. is 0·7978 at 68°, according to Regnault; 0·79381 at 60° according to Drinkwater. The sp. gr. of its vapour is 1·59. Its freedom from water may be ascertained by dropping into it a piece of anhydrous baryta, which will remain unchanged if the alcohol be free from water; but otherwise will fall to powder. Another method for determining the same point, is to allow alcohol to stand for some time, in a stoppered bottle, on anhydrous sulphate of copper. If the alcohol be anhydrous, the salt will remain white; otherwise it will become blue. (*Casoria.*) Absolute alcohol should be free from fusel oil. In view of this impurity, the Edinburgh College gives the following test. "When mixed with a little solution of nitrate of silver and exposed to bright light, it remains unchanged, or only a very scanty dark precipitate forms."

Absolute alcohol burns with a pale flame without residue, the products being carbonic acid and water. Its vapour, passed through a porcelain tube filled with pumice-stone and heated to redness, yields carbon, gaseous carbohydrogens, aldehyd, naphthaline, benzine, phenic acid, and various other substances. (*Berthelot.*) It unites in all proportions with ether and water. Its union with water is attended by condensation and a rise of temperature. When mixed with water in the proportion of 51·9 volumes of alcohol to 48·1 of water, corresponding with one eq. of the former to six of the latter, the decrease of volume is at the maximum, amounting to 3·4 per cent. The powers of absolute alcohol as a solvent are very much the same as those of officinal alcohol, noticed at *page* 62.

Composition. Absolute alcohol consists of four eqs. of carbon 24, six of hydrogen 6, and two of oxygen 16=46; or, in volumes, of four volumes of the vapour of carbon, six of hydrogen, and one of oxygen, condensed into two volumes. Its empirical formula is, therefore, $C_4H_6O_2$. Viewed as a hydrated oxide of ethyle, its formula is $C_4H_5,O+HO$.

It has been stated at *page* 60, that during the vinous fermentation sugar disappears, and the sole products are alcohol and carbonic acid, which, taken together, are equal in weight to the sugar lost. Now, the comparative composition of the substances concerned supports the opinion that these are the sole products. Preparatory to the fermentation, the cane sugar is changed into *grape sugar*, or, according to Mitscherlich and Soubeiran, into *uncrystallizable sugar*. These two

sugars, dried at 212°, consist of $C_{12}H_{12}O_{12}$. Supposing one eq. of this fermentable sugar to be the subject-matter of the change, it will be found to have a composition which admits of its being broken up into two eqs. of alcohol and four of carbonic acid, without a remainder; for $C_{12}H_{12}O_{12}=2(C_4H_6O_2)$ and $4(CO_2)$.

The reasons are not obvious which induced the Edinburgh and Dublin Colleges to include absolute alcohol in their officinal lists. It is used in no preparation of the Edinburgh Pharmacopœia, and in only two of the Dublin, in neither of which is it necessary.

Pharm. Use. Employed as a solvent in preparing Arsenici et Hydrargyri Hydriodatis Liquor.

Off. Prep. Essentia Fœniculi. B.

ALCOHOL DILUTUM. *U.S.* SPIRITUS TENUIOR. *Lond., Ed., Dub.* *Diluted Alcohol. Proof Spirit.*

"Take of Alcohol, Distilled Water, each, *a pint.* Mix them. The specific gravity of Diluted Alcohol is 0·935." *U. S.*

"Take of Rectified Spirit *two pints;* Distilled Water *a pint.* Mix them. The density of the product should be 0·912." *Ed.*

"Take of Rectified Spirit *seven pints;* Distilled Water *four pints.* Mix. The specific gravity of Proof Spirit is 0·920." *Dub.*

The London College places diluted alcohol or proof spirit in the list of the Materia Medica. The *Edinburgh* College has ordered the strongest proof spirit, its density being 0·912, which is 7 over proof. It contains 52 per cent. of absolute alcohol, and is considerably stronger than the corresponding spirit of the former Edinburgh Pharmacopœia. The *London* College directs the sp.gr. to be 0·920. When of this strength, it contains 49 per cent. of pure alcohol, and may be formed by mixing five measures of the rectified spirit of that College with three of distilled water at the temp. of 62°. The Dublin proof spirit has the sp. gr. 0·920 also, and, therefore, agrees in strength with the corresponding spirit of the London College. The diluted alcohol of the U. S. Pharmacopœia has the sp. gr. 0·935, and contains only 42 per cent. of absolute alcohol. It is, therefore, the weakest officinal proof spirit.

Medical and Pharmaceutical Uses. The medicinal effects of alcohol, as it exists in brandy and other ardent spirits, have been detailed under other heads. (See *Alcohol, U. S., Spiritus Vini Gallici,* and *Vinum Album.*) As a pure diluted spirit, however, consisting solely of alcohol and water in determinate proportions, its use is exclusively pharmaceutical. It is employed as an addition to the compound infusion of gentian, and to some of the distilled waters and preparations of vinegar, in order to preserve them from decomposition; as a menstruum for extracting the virtues of some plants, preparatory to their being brought to the state of extracts and syrups; and in preparing many of the spirits, and a few of the medicated wines. But it is in forming the tinctures that diluted alcohol is principally employed. Many of these are formed with the officinal alcohol (rectified spirit), but the majority, with diluted alcohol (proof spirit) as the menstruum. As the latter contains more than half its weight of water, it is well fitted for acting on those vegetables, the virtues of which are partly soluble in water and partly in alcohol. The apothecary, however, should never substitute the commercial proof spirit for diluted alcohol, even though it may be of the same strength, on account of the impurities in the former; but when it is recollected how variable the so called proof spirits are in strength, the objection to their use in pharmacy becomes still stronger. Thus, according to Mr. Brande, gin contains 51·6 per cent. of alcohol of 0·825; and the percentage of the same alcohol is 53·39 in brandy, 53·68 in rum, 53·90 in Irish whisky, and 54·32 in Scotch whisky. The alcohol on which these results are based already contains 11 per cent. of water. B.

ALUMEN.

Preparations of Alum.

ALUMEN EXSICCATUM. *U. S., Lond., Ed.* ALUMEN SICCATUM. *Dub. Dried Alum.*

"Take of Alum, in coarse powder, *a convenient quantity.* Melt it in a shallow iron or earthen vessel, and maintain it at a moderate heat until ebullition ceases, and it becomes dry; then rub it into powder." *U. S.*

"Take of Alum *a pound.* Melt it over the fire; then increase the heat until ebullition has ceased." *Lond.*

The *Edinburgh* and *Dublin* processes agree substantially with that of the U. S. Pharmacopœia. When alum is heated, it quickly dissolves in its water of crystallization, which, if the heat be continued, is gradually driven off; and the salt swells up exceedingly, so as to make it expedient to use a vessel, the capacity of which is at least equal to three times the bulk of the alum operated on. When the boiling up has ceased, it is a sign that all the water has been driven off.

Properties. Dried alum, sometimes called *alumen ustum* or *burnt alum*, is in the form of an opaque white power, possessing a more astringent taste than the crystallized salt. Before pulverization, it is a light, white, opaque, porous mass. During the exsiccation, it loses from 41 to 46 per cent. of its weight in dissipated water. If, however, the heat be strongly urged, some of the acid is driven off, and the loss becomes still greater. Dried alum resists the action of water for a long time, showing that the process to which it has been subjected has altered its state of aggregation. In composition it differs from crystallized alum merely in the absence of water.

Medical Properties and Uses. Dried alum has occasionally been given in obstinate constipation, with the effect of gently moving the bowels, and of affording great relief from pain. (See *Alumen.*) The dose is from five to ten grains or more. Its principal medical use is as a mild escharotic for destroying fungous flesh. B.

LIQUOR ALUMINIS COMPOSITUS. *Lond. Compound Solution of Alum.*

"Take of Alum, Sulphate of Zinc, each, *an ounce;* Distilled Water *three pints* [Imp. meas.]. Rub the Alum and Sulphate together, and dissolve in the Water; then strain." *Lond.*

This was formerly called *aqua aluminosa Bateana*, or *Bates's alum water.* It is a powerful astringent solution, and is employed for cleansing and stimulating foul ulcers, and as an injection in gleet and leucorrhœa. It is also sometimes employed as a collyrium in ophthalmia after depletion; but when used in this way it must be diluted. A convenient formula is half a fluidounce of the solution, mixed with six and a half fluidounces of rose water. B.

AMMONIA.

Preparations of Ammonia.

AMMONIÆ CARBONAS. *U. S., Ed.* AMMONIÆ SESQUICARBONAS. *Lond., Dub. Carbonate of Ammonia. Sesquicarbonate of Ammonia. Mild Volatile Alkali.*

"Take of Muriate of Ammonia *a pound;* Chalk, dried, *a pound and a half.* Pulverize them separately; then mix them thoroughly, and sublime with a gradually increasing heat." *U. S.*

The *Edinburgh* process is the same as that of the U. S. Pharmacopœia. The *London* and *Dublin Colleges* have placed this salt in the list of the Materia Medica.

In the above process, by the reciprocal action of the salts employed, the carbonic acid unites with the ammonia, generating carbonate of ammonia, and the muriatic acid with the lime, forming water and chloride of calcium. The carbonate and water sublime together as a hydrated carbonate of ammonia, and the residue is chloride of calcium. In conducting the process, the retort should be of earthenware, and have a wide cylindrical neck; and the receiver should be cylindrical, to facilitate the extraction of the sublimate. The relative quantities of chalk and muriate of ammonia, for mutual decomposition, are 50·5 of the former, and 53·42 of the latter, or one eq. of each. In the formula a great excess of chalk is taken. An excess is desirable to ensure the perfect decomposition of the muriate of ammonia; any redundancy of which would sublime along with the carbonate, and render it impure.

Carbonate of ammonia is obtained, on the large scale, usually by subliming the proper materials from an iron pot into a large earthen or leaden receiver. Sulphate of ammonia may be substituted for the muriate with much economy, as was shown by Payen. Large quantities of this carbonate are manufactured indirectly from *coal-gas liquor* and *bone spirit;* the ammoniacal products in these liquors being successively converted into sulphate, muriate, and carbonate of ammonia. (See *Ammoniæ Murias.*) The salt as first obtained has a slight odour of tar, and leaves a blackish carbonaceous matter when dissolved in acids. Hence it requires to be purified, which is effected in iron pots, surmounted with leaden heads.

Properties. Carbonate (*sesquicarbonate*) of ammonia, recently prepared, is in white, moderately hard, translucent masses, of a fibrous and crystalline appearance, a pungent ammoniacal smell, and a sharp penetrating taste. It possesses an alkaline reaction, and when held under a piece of turmeric paper changes it to brown, owing to the escape of monocarbonate of ammonia. When long or carelessly kept, it gradually passes into the state of bicarbonate, becoming opaque and friable, and falling into powder. It is soluble without residue in about four times its weight of cold water, and is decomposed by boiling water with effervescence. According to Dr. Barker (*Observations on the Dublin Pharmacopœia*), it dissolves abundantly in diluted alcohol, as also in heated alcohol of the sp. gr. 0·836, with effervescence of carbonic acid. When heated on a piece of glass, it should evaporate without residue, and, if turmeric paper held over it undergoes no change, it has passed into bicarbonate. As now prepared from coal gas liquor, it usually contains traces of tarry matter, which gives a dark colour to its solution in acids. When saturated with nitric acid, neither chloride of barium nor nitrate of silver causes a precipitate. The non-action of these tests shows the absence of sulphate and muriate of ammonia. It is decomposed by acids, the fixed alkalies and their carbonates, lime-water and magnesia, solution of chloride of calcium, alum, acid salts, such as bitartrate and bisulphate of potassa, solutions of iron (except the tartrate of iron and potassa), corrosive sublimate, the acetate and subacetate of lead, and the sulphates of iron and zinc.

Composition. It consists of three eqs. of carbonic acid 66, two of ammonia 34, and two of water 18=118; or, which comes to the same thing, of one eq. of bicarbonate 61, and one of monocarbonate 39, combined with the same quantity of water. The medicinal carbonate of ammonia is, therefore, when perfect, a *sesquicarbonate,* as it is called by the London and Dublin Colleges. Dalton and Scanlan, however, have rendered it probable that it is a double salt; for, when treated with a small quantity of cold water, monocarbonate is dissolved

and bicarbonate left. When converted into bicarbonate by exposure to the air, each eq. of the medicinal salt loses one eq. of monocarbonate, a change which leaves the acid and base in the proper proportion to form the bisalt. The mutual decomposition of the salts, employed in its preparation, would generate, if no loss occurred, the monocarbonate, and not the sesquicarbonate. The way in which the latter salt is formed may be thus explained. By the mutual decomposition of three eqs. of muriate of ammonia and of chalk respectively, three eqs. of monocarbonate of ammonia, three of water, and three of chloride of calcium are generated. During the operation, however, one eq. of ammonia, and one of water, forming together oxide of ammonium, are lost; so that there remain to be sublimed, three eqs. of carbonic acid, two of ammonia, and two of water; or, in other words, the exact constituents of the hydrated sesquicarbonate. When this is re-sublimed in the process of purification, two eqs. of the salt lose one eq. of carbonic acid, and become one eq. of 5-4 carbonate of ammonia.

Medical Properties and Uses. Carbonate of ammonia is stimulant, diaphoretic, antispasmodic, powerfully antacid, and in large doses emetic. Under certain circumstances it may prove expectorant; as when, in the last stages of phthisis, it facilitates, by increasing the muscular power, the excretion of the sputa. As a stimulant, it is exhibited principally in typhus fever, and very frequently in connexion with wine whey. Its principal advantage, in this disease, is its power to increase the action of the heart and arteries without unduly exciting the brain. It is employed, with a view to the same effect, and as an antacid, in certain stages of atonic gout, and in the derangement of the stomach supervening on habits of irregularity and debauchery. As a diaphoretic, it is resorted to in gout and chronic rheumatism, particularly the latter, in conjunction with guaiac. Dr. Pereira has employed it in many cases of epilepsy with benefit. In diabetes it has been recommended by Dr. Barlow in England, and Bouchardat in France. In cases of scrofula attended with languid circulation and dry skin, it is said to produce excellent effects. It is very seldom used as an emetic; but is supposed to act with advantage, in this way, in some cases of paralysis. In psoriasis and lepra vulgaris, Cazenave has used it with remarkable success. Two cases of glanders, successfully treated chiefly with five-grain doses of carbonate of ammonia, repeated every hour or two hours, are reported by Dr. Mackensie, of London. (*Ranking's Abstract*, No. 18, p. 230.) As an external application, it is rubefacient, and may be employed in several ways. Reduced to fine power, and mixed with some mild ointment, it is useful in local rheumatism. One part of it, incorporated with three parts of extract of belladonna, forms a plaster very efficacious in relieving local and spasmodic pains. Coarsely bruised, and scented with oil of lavender, it constitutes the common smelling salts, so much used as a nasal stimulant in syncope and hysteria. The ordinary dose is five grains, every two, three, or four hours, given in the form of pill or mixture; and as an emetic, thirty grains, to be repeated if necessary, and assisted by free dilution. It should never be given in powder, on account of its volatile nature. Pills of it may be made up with some vegetable extract, as of gentian, for example, and should be dispensed in a wide-mouthed vial, and not in a box.

Carbonate of ammonia is used as a chemical agent in preparing Zinci Oxidum and Ferrum Tartarizatum. It is sometimes employed to make effervescent draughts, 20 grains of the salt requiring for this purpose 6 fluidrachms of lemon juice, 24 grains of citric acid, or 25½ grains of tartaric acid.

Off. Prep. Ammoniæ Bicarbonas; Cuprum Ammoniatum; Liquor Ammoniæ Acetatis; Liquor Ammoniæ Citratis; Liquor Ammoniæ Sesquicarbonatis; Potassæ Bicarbonas; Potassæ Carbonas Purum. B.

AMMONIÆ BICARBONAS. *Dub.* *Bicarbonate of Ammonia.*

"Take of Commercial Sesquicarbonate of Ammonia *any convenient quantity.* Reduce it to a fine powder, and having spread it on a sheet of paper, expose it to the air for twenty-four hours. Let it be now enclosed in a well stopped bottle." *Dub.*

This salt is officinal only in the Dublin Pharmacopœia. The sesquicarbonate, by exposure to the air, loses monocarbonate by evaporation, and is converted into bicarbonate. This salt is an opaque white powder, having a faint ammoniacal taste and smell. It is less soluble in water than the sesquicarbonate, requiring eight times its weight of that liquid to dissolve it. It possesses, though in an inferior degree, the same medical properties as the sesquicarbonate, and furnishes, according to Dr. Barker, of Dublin, the means of prescribing ammonia in a convenient and palatable form. The dose is from six to twenty-four grains, dissolved in cold water, as hot water decomposes the salt.

The curious fact has been ascertained by Mr. L. Thompson, of Newcastle on Tyne, that bicarbonate of ammonia is exhaled from the lungs in the amount of about three grains in twenty-four hours. (*Philos. Mag.* for Feb. 1847.) B.

LIQUOR AMMONIÆ SESQUICARBONATIS. *Lond.* AMMONIÆ CARBONATIS AQUA. *Ed.* *Solution of Sesquicarbonate of Ammonia. Water of Carbonate of Ammonia.*

"Take of Sesquicarbonate of Ammonia *four ounces;* Distilled Water *a pint* [Imp. meas.]. Dissolve and strain." *Lond.*

The *Edinburgh* solution is of the same strength as the London.

This preparation may be viewed as a saturated aqueous solution of carbonate of ammonia. It is very properly omitted in the United States Pharmacopœia; as it is liable to change by keeping, and the solution of the salt may be readily ordered of any desired strength in prescription. The dose is from half a fluidrachm to a fluidrachm, given in any bland liquid.

Off. Prep. Linimentum Ammoniæ Sesquicarbonatis; Pilulæ Cupri Ammoniati. B.

AMMONIÆ HYDRO-SULPHURETUM. *Dub.* *Hydrosulphuret of Ammonia. Solution of Hydrosulphate of Ammonia.*

"Take of Solution of Ammonia *four fluidounces* [Imp. meas.]; Sulphuret of Iron *one ounce and a half* [avoirdupois]; Oil of Vitriol of Commerce *one fluidounce and a half* [Imp. meas.]; Water *fifteen ounces* [avoird.]; Distilled Water *two ounces* [avoird.]. Place the Sulphuret of Iron and Water in a two-necked bottle, and, adding the Oil of Vitriol by degrees through a safety funnel, conduct by suitable tubes the sulphuretted hydrogen which is disengaged, first through the Distilled Water placed in a small intermediate vial, and then to the bottom of a bottle containing the Ammonia, the neck of the latter, through which the glass tube conveying the gas passes, being loosely plugged with tow. If, when the development of gas has ceased, a drop of the ammoniacal liquid, added to a saturated solution of sulphate of magnesia, gives no precipitate, the preparation is completed; but should a precipitate occur, the hydrosulphuret still contains free ammonia, and must, therefore, be again subjected to the action of a stream of sulphuretted hydrogen. The Hydrosulphuret of Ammonia must be kept in a green glass bottle, furnished with an accurately ground stopper. The specific gravity of this solution is 0·999." *Dub.*

This preparation is a solution of hydrosulphate of ammonia in water, and is formed by passing a stream of hydrosulphuric acid gas (sulphuretted hydrogen) through water of ammonia, contained in a Wolfe's bottle. The hydrosulphuric acid is generated by the action of dilute sulphuric acid on sulphuret of iron. The water yields its oxygen to the iron forming protoxide of iron, with which the

sulphuric acid combines; while the hydrogen of the water, uniting with the sulphur, generates the hydrosulphuric acid.

Properties. Hydrosulphuret of ammonia is a liquid of a greenish-yellow colour, very fetid smell, and acrid, disagreeable taste. It is characterized by giving coloured precipitates with neutral metallic solutions, for which it is much used as a test. It is decomposed by acids, which cause the escape of hydrosulphuric acid with effervescence, and the deposition of sulphur. The salt present in it appears to be a bihydrosulphate, consisting of two eqs. of hydrosulphuric acid 34, and one of ammonia 17=51.

Medical Properties. This preparation is sedative, lessening the action of the heart in a remarkable degree, and producing nausea, vomiting, vertigo, and drowsiness. It has been used in diabetes mellitus, in which it was proposed as a remedy by Dr. Cruickshank, for the purpose of lessening the morbid appetite which often attends that affection, and has been employed by Dr. Rollo and others. The dose is from five to six drops in a tumblerful of water three or four times a day, to be gradually increased until giddiness is produced. B.

LIQUOR AMMONIÆ. *U. S.* AMMONIÆ LIQUOR. *Lond., Dub.* AMMONIÆ AQUA. *Ed.* AQUA AMMONIÆ. *Solution of Ammonia. Water of Ammonia.*

"Take of Muriate of Ammonia, in fine powder, Lime, each *a pound;* Distilled Water *a pint;* Water *nine fluidounces.* Break the Lime in pieces, and pour the Water upon it in an earthen or iron vessel; then cover the vessel, and set it aside till the Lime falls into powder and becomes cold. Mix this thoroughly with the Muriate of Ammonia in a mortar, and immediately introduce the mixture into a glass retort. Place the retort upon a sand-bath, and adapt to it a receiver, previously connected, by means of a glass tube, with a quart bottle containing the Distilled Water. Then apply heat, to be gradually increased till the bottom of the iron vessel containing the sand becomes red-hot; and continue the process so long as ammonia comes over. Remove the liquor contained in the quart bottle, and for every fluidounce of it add three and a half fluidrachms of Distilled Water, or so much as may be necessary to raise its specific gravity to 0·960. Keep the solution in small bottles well stopped. Solution of Ammonia may also be prepared by mixing one part, by measure, of Stronger Solution of Ammonia with two parts of Distilled Water." *U. S.*

"Take of Sal Ammoniac, in fine powder, fresh-burned Lime, each *eight ounces* [avoirdupois]; Water *four ounces* [avoird.]; Distilled Water *sixteen ounces* [avoird.]. Pour on the Lime the four ounces of Water, and, when the slaked lime has cooled, mix it well with the Sal Ammoniac by trituration in a mortar. Introduce the mixture into a matrass of glass, or, if such can be had, an iron bottle, and, having closed this by means of a cork perforated by a suitable tube for conveying off the gas, apply, with the intervention of sand, a gentle heat, which must be gradually augmented, and cause the ammonia, as it is evolved, to pass first through a small Wolfe's bottle furnished with a syphon safety-tube containing mercury, and thence to the bottom of an [Imperial] pint bottle containing the Distilled Water. The temperature of the latter must be prevented from rising as the absorption of the gas proceeds, by surrounding the bottle which contains it with cold water, which should be frequently renewed. The specific gravity of this solution is 0·950." *Dub.*

The *London* College now places solution of ammonia in the Materia Medica list, directing it to have the specific gravity 0·960.

The *Edinburgh* process includes the formation of Liquor Ammoniæ Fortior and this preparation at one operation. The process has been quoted at length and explained under another head. (See *Liquor Ammoniæ Fortior.*) The solution of ammonia of this College is directed to have the sp. gr. 0·960.

The object of the above processes is to obtain a weak aqueous solution of the alkaline gas ammonia. The muriate of ammonia is decomposed by the superior affinity of the lime for its acid, ammonia is disengaged, and the lime, combining with the acid, forms chloride of calcium and water. The lime is slaked to render it pulverulent, in which state it acts more readily on the muriate of ammonia. The Wolfe's bottle is intended to retain any water holding in solution undecomposed muriate, or the oily matter sometimes contained in this salt, as well as other impurities, which may be driven over by the heat; while the pure gas passes forward through the glass tube into the bottle containing the distilled water, which should not fill it, on account of the increase of bulk which the water acquires during the absorption of the gas. The tube should continue down to near the bottom of the bottle, and pass through a cork, loosely fitting its mouth. To prevent the regurgitation of the water from the bottle into the intermediate vessel, the latter should be furnished with a Welter's tube of safety, as directed by the Dublin College. Large bottles are improper for keeping the water of ammonia obtained; as, when they are partially empty, the atmospheric air contained within them is apt to furnish a little carbonic acid to the ammonia.

In preparing solution of ammonia, the Pharmacopœias now agree in using equal weights of muriate of ammonia and lime for generating the gaseous ammonia. This proportion gives a great excess of lime, compared with the quantity required if determined by the equivalents. But in practice it is found advantageous to have an excess, as well to insure the full decomposition of the muriate of ammonia, as to make up for accidental impurities in the lime.

Solution of ammonia is obtained on the large scale by manufacturing chemists, with greater economy, from the sulphate instead of the hydrochlorate of ammonia.

The *U. S.*, *London*, and *Edinburgh* Pharmacopœias give directions for diluting *Liquor Ammoniæ Fortior*, so as to reduce it to the strength of *Liquor Ammoniæ*. This is effected by mixing one measure of the stronger preparation with two measures of distilled water (*U. S.*, *Lond.*), or with two and a half measures (*Ed.*). By dilution to this extent the stronger solution is brought uniformly to the sp. gr. 0·960; the Edinburgh solution requiring more water, because more concentrated.

Properties. The properties of Liquor Ammoniæ Fortior have already been given. (See *page* 84.) Those of the officinal solution of ammonia, described in this place, are the same in kind, but weaker in degree. Its specific gravity in the U. S., London, and Edinburgh Pharmacopœias is the same, 0·960; in the Dublin, 0·950. When of the density 0·960, 100 grains of it saturate 30 grains of officinal sulphuric acid, and contain nearly 10 grains of ammonia. It is incompatible with acids, and with acidulous and most earthy and metallic salts; but it does not decompose the salts of lime, baryta, or strontia, and decomposes those of magnesia only partially. If precipitated by lime-water, the ammonia is partly carbonated. When saturated with nitric acid, it should give no precipitate with carbonate of ammonia, nitrate of silver, or chloride of barium. A precipitate with the first indicates earthy matter; with the second muriatic acid or a chloride; with the third sulphuric acid or a sulphate. Commercial solution of ammonia sometimes contains *pyrrol*, *naphthaline*, and other soluble impurities. These may be detected by the solution being reddened by nitric acid, and, after having been supersaturated with muriatic acid, by its tinging a slip of fir wood of a rich purple colour, characteristic of pyrrol. (*Maclagan.*) The source of these impurities is coal-gas liquor, from which the ammoniacal compounds are largely obtained.

Composition. Water is capable of absorbing 670 times its volume of ammoniacal gas at 50°, and increases its bulk about two-thirds. But the officinal solution of ammonia is by no means a saturated one. Thus, the ammonia con-

tained in the U. S., London, and Edinburgh preparations is about 10 per cent.; in the Dublin, about 12½ per cent. The following table gives the per centage of ammoniacal gas in aqueous solutions of different densities.

Specific Gravity.	Ammonia per cent.	Specific Gravity.	Ammonia per cent.	Specific Gravity.	Ammonia per cent.
0·8750	32·50	0·9326	17·52	0·9545	11·56

0·9255	19·54				

Medical Properties and Uses. Solution of ammonia is stimulant, sudorific, antacid, and rubefacient. It stimulates more particularly the heart and arteries, without unduly exciting the brain. As a stimulant, it is occasionally employed in paralysis, hysteria, syncope, asphyxia, and similar affections. In the same complaints it is often applied to the nostrils with advantage; but, in cases of insensibility, care must be taken not to carry the application too far, for fear of inducing dangerous and even fatal bronchitis. As an antacid, it is one of the best remedies in heartburn, and for the relief of sick headache when dependent on acidity of stomach. In these cases it acts usefully also by stimulating the stomach. In the bites of poisonous serpents, it has long been deemed a powerful antidote. A successful case, caused by the bite of a cobra de capello, is reported by Dr. W. Chalmers, formerly of Bengal, in which the solution of ammonia was chiefly relied on. It has been recommended by Dr. Guérard as an application to burns, which have proceeded to the extent of rubefaction or raising the cuticle, as a means of relieving the pain and hastening the cure. (*Journ. de Pharm.*, Jan. 1849.) As a rubefacient it is employed united with oils in the form of volatile liniment. (See *Linimentum Ammoniæ.*) The dose is from ten to thirty drops, largely diluted with water to prevent its caustic effect on the mouth and throat. When swallowed in an over-dose, its effects are those of a corrosive poison. The best antidotes are vinegar and lemon-juice, which act by neutralizing the ammonia, and must be promptly applied to be useful. The consecutive inflammation must be treated on general principles.

Pharm. Uses. To prepare Aconitia; Calcis Phosphas Præcipitatum; Ferri Oxidum Hydratum; Morphia; Morphiæ Acetas; Pulvis Antimonialis, *Dub.;* Spiritus Ætherеus Nitrosus; Strychnia; Veratria.

LIQUOR AMMONIÆ ACETATIS. *U. S.*, *Lond.* AMMONIÆ ACETATIS AQUA. *Ed.* AMMONIÆ ACETATIS LIQUOR. *Dub.* SPIRITUS MINDERERI. *Solution of Acetate of Ammonia. Spirit of Mindererus.*

"Take of Diluted Acetic Acid *two pints;* Carbonate of Ammonia, in powder, *a sufficient quantity.* Add the Carbonate of Ammonia gradually to the Acid until it is saturated." *U. S.*

The *London* and *Dublin* processes are substantially the same as the above.

"Take of Distilled Vinegar (from French Vinegar in preference) *twenty-four fluidounces* [Imperial measure]; Carbonate of Ammonia *an ounce.* Mix them and dissolve the salt. If the solution has any bitterness, add by degrees a little Distilled Vinegar till that taste be removed. The density of the Distilled Vinegar should be 1·005, and that of the Aqua Acetatis Ammoniæ 1·011." *Ed.*

This preparation is an aqueous solution of acetate of ammonia. The process by which it is formed constitutes a case of single elective affinity. The acetic acid decomposes the carbonate, combines with the ammonia forming the acetate of ammonia, and disengages the carbonic acid with effervescence. The Edinburgh is now the only British Pharmacopœia that uses distilled vinegar in forming this preparation; the London and Dublin Colleges having followed in their recent Pharmacopœias the U. S. process, which takes the officinal diluted acetic acid instead of distilled vinegar for saturating the carbonate. (See *Acidum Aceticum Dilutum.*) The use of diluted acetic acid is preferable to that of distilled vinegar; for, besides furnishing a solution of the acetate of uniform strength, a result which cannot be attained by the employment of distilled vinegar, it avoids the production of a brownish solution, which uniformly follows the use of the latter, especially when it has been condensed in a metallic worm. The quantity of carbonate of ammonia, necessary to saturate a given weight of the acid of average strength, cannot be laid down with precision, on account of the variable quality of the salt. The preparation, when made with the diluted acetic acid of the U. S. Pharmacopœia, contains about six per cent. of acetate of ammonia. It is more convenient to add the salt to the acid than the acid to the salt; as the point of saturation is thus more easily attained. This point is best ascertained by the alternate use of turmeric and litmus paper; and it is a good rule to allow a slight acidity to prevail, which will be due to carbonic acid dissolved in the liquid, and will disappear as soon as this acid is dissipated by time.

Properties. Solution of acetate of ammonia, when made of pure materials, is a limpid and colourless liquid without smell. Its taste is saline, and resembles that of a mixture of nitre and sugar. When it contains an excess of alkali, its taste is bitterish. It should be freshly prepared at short intervals; as its acid becomes decomposed, and a portion of carbonate of ammonia is generated. As formerly prepared, under the name of *spiritus Mindereri*, it was made from the impure carbonate of ammonia containing animal oil, which modified the preparation by giving rise to a portion of ammoniacal soap. When pure it is not coloured by hydrosulphuric acid, nor precipitated by chloride of barium. Nitrate of silver precipitates crystals of acetate of silver, soluble in water and especially in nitric acid. An insoluble precipitate with this test is chloride of silver, and shows the presence of muriatic acid. Potassa disengages ammonia, sulphuric acid, acetous vapours. When evaporated to dryness, the residue is wholly dissipated by heat, with the smell of ammonia. It is incompatible with acids, the fixed alkalies and their carbonates, lime-water, magnesia, sulphate of magnesia, corrosive sublimate, the sulphates of iron, copper, and zinc, and nitrate of silver. When it contains free carbonic acid, it produces with the acetate or subacetate of lead a precipitate of carbonate of lead, which, being mistaken for the sulphate, has sometimes led to the erroneous conclusion that sulphuric acid was present in the distilled vinegar, when this has been employed. Acetate of ammonia, the salt in solution in this preparation, is difficultly crystallizable, and very deliquescent. It may be obtained by sublimation from a mixture of equal parts of dry acetate of potassa or of lime, and muriate of ammonia. It consists of one eq. of acetic acid 51, and one of ammonia 17=68. When crystallized it contains seven eqs. of water 63.

Medical Properties and Uses. Solution of acetate of ammonia is a valuable diaphoretic, much employed in febrile and inflammatory diseases. According to the indications to be answered by its use, it is variously combined with nitre and antimonials, camphor and laudanum. If, instead of promoting its determination to the skin by external warmth, the patient walk about in a cool air, its action will be directed to the kidneys. It is sometimes used externally as a discutient. Mr. Brande speaks of it as an excellent application in mumps, applied hot upon

a piece of flannel. In the hydrocele of children, it is strongly recommended by Dr. Maushner, applied by means of compresses kept constantly moist. (*Journ. de Pharm.*, 3e *sér.*, v. 317.) Mixed in the quantity of a fluidounce with seven fluidounces of rosewater, and two fluidrachms of laudanum, it forms a useful collyrium in chronic ophthalmia. The late Dr. A. T. Thomson used it as a lotion with good effect in porrigo affecting the scalp. The dose is from half a fluidounce to a fluidounce and a half, every three or four hours, mixed with water and sweetened with sugar. It proves sometimes very grateful to febrile patients, when prescribed with an equal measure of carbonic acid water. B.

LIQUOR AMMONIÆ CITRATIS. *Lond.* *Solution of Citrate of Ammonia.*

"Take of Citric Acid *three ounces;* Distilled Water *a pint* [Imperial measure]; Sesquicarbonate of Ammonia *two ounces and a half,* or *a sufficient quantity.* Dissolve the Acid in the Water, and add the Sesquicarbonate to saturation." *Lond.*

In consequence of the want of correspondence between the London measures and those in use with us, it will be more convenient to make this preparation in accordance with the U. S. process for Solution of Citrate of Potassa. The result will not be materially different. All that is required is to saturate lemon or lime juice, or an equivalent solution of citric acid, with carbonate of ammonia. Such a solution may be made by rubbing half an ounce of citric acid first with two minims of oil of lemons, and then with half a pint of water till it is dissolved.

A more elegant mode of exhibition is that of an extemporaneous effervescing draught. To half a fluidounce of lemon juice mixed with an equal measure of water, or to a fluidounce of a solution of citric acid containing 17 grains of the acid, is to be added half a fluidounce of a solution containing 13 grains of carbonate of ammonia, and the mixture is to be administered while effervescing.

The solution of citrate of ammonia is given as a refrigerant diaphoretic in febrile complaints, and is especially applicable to typhoid fevers, with a hot and dry skin. A tablespoonful of the saturated solution, or the whole quantity above mentioned of the effervescing preparation, may be repeated every hour, two, or three hours. W.

SPIRITUS AMMONIÆ. *U. S.*, *Ed.* *Spirit of Ammonia.*

"Take of Muriate of Ammonia, in fine powder, Lime, each *a pound;* Alcohol *twenty fluidounces;* Water *nine fluidounces.* Slake the lime with the Water, mix it with the Muriate of Ammonia, and proceed in the manner directed for Solution of Ammonia, the Alcohol being introduced into the quart bottle instead of Distilled Water. When all the ammonia has come over, remove the liquor contained in the quart bottle, and keep it in small bottles well stopped." *U. S.*

"Take of Rectified Spirit *two pints* [Imperial measure]; fresh-burnt Lime *twelve ounces* [a pound]; Muriate of Ammonia, in very fine powder, *eight ounces;* Water *six fluidounces and a half* [Imp. meas.]. Let the Lime be slaked with the Water in an iron or earthenware vessel, and cover the vessel till the powder be cold; mix the Lime and Muriate of Ammonia quickly and thoroughly in a mortar, and transfer the mixture at once into a glass retort; adapt to the retort a tube which passes nearly to the bottom of a bottle containing the Rectified Spirit; heat the retort in a sand-bath gradually, so long as anything passes over, preserving the bottle cool. The bottle should be large enough to contain one-half more than the spirit used." *Ed.*

Spirit of ammonia is now officinal in the U. S. and Edinburgh Pharmacopœias only; the London and Dublin Colleges having dismissed the preparation under the same name. It is a solution of caustic ammonia in rectified spirit. The proportions of the ingredients of the *U. S.* formula are so adjusted as to give a preparation, containing between 10 and 11 per cent. of ammonia, and capable of

saturating about 30 per cent. of officinal sulphuric acid. Accordingly it agrees, as it was intended it should, in ammoniacal strength, with the U. S. *Liquor Ammoniæ.* Its sp. gr. is 0·831, or thereabouts. The *Edinburgh* spirit of ammonia may be roughly estimated to be not quite one-third as strong as that of the U. S. Pharmacopœia; for the ammonia extricated from the same quantity of muriate of ammonia, is passed into three times as much rectified spirit. The density of the Edinburgh spirit is "about 0·845." As rectified spirit becomes lighter by the absorption of ammoniacal gas, it is evident that the alcoholic menstruum, in the Edinburgh preparation, gains water as well as ammonia in the distillation. This addition of water to the product is prevented by the intermediate receiver used in the U. S. process, and consequently the spirit of ammonia obtained has a less specific gravity than that of rectified spirit.

Properties. The *U. S.* spirit of ammonia, formerly called *ammoniated alcohol*, is a transparent colourless liquid, having a strong ammoniacal odour, and acrid taste. When good it does not effervesce with diluted muriatic acid; but if old or carelessly kept, it is apt to be partially carbonated, as shown by this test. It, however, absorbs carbonic acid more slowly than Liquor Ammoniæ. The *Edinburgh* preparation agrees in nature with the *U. S.* spirit, but is only one-third its strength.

Medical Properties and Uses. Spirit of ammonia is stimulant and antispasmodic, and is given in hysteria, flatulent colic, and nervous debility. It is, however, not much used; the aromatic spirit, which is pleasanter and has similar properties, being preferred. The dose of the U. S. preparation is from ten to thirty drops in a wineglassful of water; of the Edinburgh from thirty drops to a fluidrachm. Spirit of ammonia dissolves resins, gum-resins, camphor, and the volatile oils. The Edinburgh College uses its spirit for making the aromatic and fetid spirits of ammonia, and the *ammoniated tinctures*, as is seen by the subjoined list. The U. S. spirit enters into no officinal preparation.

Off. Prep. Spiritus Ammoniæ Aromaticus, *Ed.;* Spiritus Ammoniæ Fœtidus, *Ed.;* Tinctura Castorei Ammoniata; Tinct. Guaiaci Ammoniata, *Ed.;* Tinct. Opii Ammoniata; Tinct. Valerianæ Ammoniata, *Ed.* B.

SPIRITUS AMMONIÆ AROMATICUS. *U. S., Lond., Ed., Dub.* *Aromatic Spirit of Ammonia.*

"Take of Muriate of Ammonia *five ounces;* Carbonate of Potassa *eight ounces;* Cinnamon, bruised, Cloves, bruised, each, *two drachms;* Lemon Peel *four ounces;* Alcohol, Water, each, *five pints.* Mix them and distil seven pints and a half." *U. S.*

The London formula is the original of the above, and need not be quoted.

"Take of Spirit of Ammonia *eight fluidounces;* Volatile Oil of Lemon Peel *a fluidrachm;* Volatile Oil of Rosemary *a fluidrachm and a half.* Dissolve the Oils in the Spirit by agitation." *Ed.*

"Take of Rectified Spirit *three pints;* Stronger Solution of Ammonia *six fluidounces;* Oil of Lemon *half a fluidounce;* Oil of Nutmeg *two fluidrachms;* Oil of Cinnamon *half a fluidrachm.* Dissolve the Oils in the Spirit, and add the Solution of Ammonia. Mix with agitation and filter. The specific gravity of this solution is 0·852." *Dub.* The measures used are Imperial.

The *London* and *U. S.* aromatic spirit of ammonia is made by impregnating the menstruum with monocarbonate of ammonia, formed by double decomposition between muriate of ammonia and carbonate of potassa. Thus the product is a spirituous solution of the monocarbonate, impregnated with aromatics. The aromatic spirit of the *Edinburgh* College is a mere solution of certain volatile oils in the caustic simple spirit of that College. The *Dublin* College, in its revised Pharmacopœia of 1850, ammoniates rectified spirit with stronger solution of ammonia, and impregnates the product with certain volatile oils.

The *U. S.* and *London* aromatic spirits are the same, and have the sp. gr. 0·918. The *Edinburgh* and *Dublin* preparations are much stronger, being rectified spirit highly impregnated with caustic ammonia. The density of the Edinburgh preparation is not given, that of the Dublin is 0·852.

Medical Properties and Uses. Aromatic spirit of ammonia is fitted to fulfill the same indications as the simple spirit; but is much more used on account of its grateful taste and smell. It is advantageously employed as a stimulant antacid in sick headache. The dose of the U. S. and London spirit is from thirty drops to a fluidrachm or more, sufficiently diluted with water; that of the Edinburgh and Dublin, about one-third as much. The spirit is compatible with sulphate of magnesia, and may be usefully added to aperient draughts of that salt, to render them less offensive to the stomach.

Off. Prep. Tinctura Colchici Composita; Tinct. Guaiaci Ammoniata, *U. S., Lond.;* Tinct. Valerianæ Ammoniata, *U. S., Lond.* B.

SPIRITUS AMMONIÆ FŒTIDUS. *Lond., Ed., Dub. Fetid Spirit of Ammonia.*

"Take of Hydrochlorate [Muriate] of Ammonia *ten ounces;* Carbonate of Potassa *sixteen ounces;* Rectified Spirit, Water, each, *three pints* [Imperial measure]; Assafetida *five ounces.* Mix them; then with a slow fire distil three pints [Imp. meas.]." *Lond.* Sp. gr. 0·861.

"Take of Spirit of Ammonia *ten fluidounces and a half* [Imp. meas.]; Assafetida *half an ounce.* Break the Assafetida into small fragments, digest it in the Spirit for twelve hours, and distil over ten fluidounces and a half by means of a vapour-bath heat." *Ed.*

"Take of Assafetida *one ounce and a half* [avoirdupois]; Rectified Spirit *one pint and a half* [Imperial measure]; Stronger Solution of Ammonia *three fluidounces.* Break the Assafetida into small pieces, and macerate it in the Spirit for twenty-four hours; then distil off the entire of the Spirit, and mix the products with the Solution of Ammonia. The sp. gr. of this preparation is 0·849." *Dub.*

Of these preparations that of the London College is mainly an alcoholic solution of Carbonate of Ammonia; those of the Edinburgh and Dublin Colleges a similar solution of caustic ammonia. The small proportion of the volatile oil of assafetida can have little other effect than to impart a disagreeable odour and taste. The spirit is colourless at first, but becomes brownish with age. It is given in hysteria in doses of from thirty drops to a fluidrachm. W.

ANTIMONIUM.

Preparations of Antimony.

ANTIMONII TERCHLORIDI LIQUOR. *Dub. Solution of Terchloride of Antimony.*

"Take of Prepared Sulphuret of Antimony *one pound* [avoirdupois]; Muriatic Acid of Commerce *four pints* [Imp. meas.]. Upon the Sulphuret, placed in a porcelain capsule, pour the Acid, and, constantly stirring, apply to the mixture, beneath a flue with a good draught, a gentle heat, which must be gradually augmented as the development of gas begins to slacken, and finally carried to ebullition, and maintained at this temperature for fifteen minutes. The vessel being now removed from the fire, let its liquid contents be separated by filtration through calico, returning what passes through first, in order that a perfectly clear solution may be obtained. Transfer the liquid to another capsule, and having boiled it down to the bulk of one quart [Imp. meas.], allow it to cool,

and preserve it in a bottle, furnished with a well-ground glass stopper. The specific gravity of this solution is 1·470." *Dub.*

When tersulphuret of antimony is dissolved by the aid of heat in muriatic acid, a double decomposition takes place, resulting in the formation of terchloride of antimony and hydrosulphuric acid (sulphuretted hydrogen), which gives rise to effervescence. As this gas is exceedingly offensive and deleterious, the materials, during the reaction, are directed to be placed under a flue with a good draught. After the reaction is over, the resulting aqueous solution of terchloride of antimony, after having been strained, is boiled down to a determinate volume.

Properties. Solution of terchloride of antimony is a pale-yellow, transparent, dense liquid, possessing caustic properties. When of a deep-red colour, it is impure from the presence of iron. Its sp. gr., concentrated to the extent directed by the Dublin College, is 1·470. When it is distilled, water, the excess of muriatic acid, and any tersulphuret of arsenic that may happen to be present, are first expelled, and afterwards the terchloride volatilizes. The pure terchloride may be obtained by changing the receiver, as soon as the distilled product concretes on cooling. Pure terchloride of antimony, called by the earlier chemists *butter of antimony*, is a white, readily fusible solid, of the consistence of butter, deliquescent and powerfully caustic, and volatilizable under an obscure red heat. It was formerly used in medicine as a caustic. It usually acts without causing much pain or inflammation, and, after the separation of the eschar, forms a clean, healthy ulcer.

Solution of terchloride of antimony is a new officinal of the Dublin Pharmacopœia of 1850, and was probably introduced not as a therapeutic agent, but as a source of the officinal oxide of antimony.

Off. Prep. Antimonii Oxydum. B.

ANTIMONII OXIDUM. *Ed.* ANTIMONII OXYDUM. *Dub.* *Oxide of Antimony. Teroxide of Antimony.*

"Take of Sulphuret of Antimony, in fine powder, *four ounces;* Muriatic Acid (commercial) *a pint* [Imp. meas.]; Water *five pints* [Imp. meas.]. Dissolve the Sulphuret in the Acid with the aid of a gentle heat; boil for half an hour; filter; pour the fluid into the Water; collect the precipitate on a calico filter; wash it well with cold water, then with a weak solution of carbonate of soda, and again with cold water till the water ceases to affect reddened litmus paper. Dry the powder over the vapour bath." *Ed.*

"Take of Solution of Terchloride of Antimony *sixteen fluidounces* [Imp. meas.]; Water *two gallons* [Imp. meas.]; Solution of Caustic Potash *one pint* [Imp. meas.]; Distilled Water *a sufficient quantity.* Pour the antimonial Solution into the Water, and, having stirred the mixture well, set it by until the white precipitate which forms has subsided. Draw off the supernatant liquid by decantation, or the syphon, and having agitated the sediment with a gallon of Distilled Water, allow the whole to stand until the Oxide has fallen to the bottom. Decant again, and having placed the sediment on a calico filter, wash it with Distilled Water until the liquid which trickles through reddens blue litmus paper only in a very slight degree. The precipitate is now to be shaken occasionally for half an hour with the Solution of Caustic Potash, and then washed on a filter with boiling Distilled Water, until the washings cease to give a precipitate on being dropped into an acid solution of nitrate of silver. Lastly, let the product be dried at a heat not exceeding 120°." *Dub.*

In these processes the teroxide of antimony is obtained from the solution of the terchloride, formed by a step of the Edinburgh formula, but by a separate formula of the Dublin Pharmacopœia. By dissolving tersulphuret of antimony in muriatic acid, the Edinburgh College forms the Dublin solution of terchloride

of antimony, though the College does not give it a distinct name. When this solution is poured into a large quantity of water, there is precipitated a white powder, formerly called *powder of Algaroth* (see *Appendix*), which is an oxychloride, consisting of nine eqs. of teroxide and two of terchloride. The terchloride is in great part decomposed by the water, the elements of which convert it into muriatic acid and teroxide. The muriatic acid remains in solution, while the teroxide falls in union with a small proportion of terchloride, forming the oxychloride. The oxychloride is first washed with abundance of water to separate adhering muriatic acid, and afterwards acted upon by a solution of alkali (carbonate of soda, *Ed.*, caustic potassa, *Dub.*) to remove the terchloride; when the teroxide is left, and only requires to be washed with water in order to render it pure. The last washing separates the chloride of sodium or potassium, resulting from the decomposition of the terchloride; and the water of this washing is tested, in the Dublin formula, for the absence of a chloride by nitrate of silver. In making this oxide, the apothecary should give the preference to the Dublin formula, as more precise in its directions.

Properties. Teroxide of antimony is a snow-white, heavy powder, permanent in the air, insoluble in water, but readily soluble in muriatic or tartaric acid, or in a boiling solution of bitartrate of potassa. When heated in close vessels, it becomes yellow, fuses at a full red heat, and finally sublimes in crystalline needles. When cooled from a state of fusion, it forms a fibrous crystalline mass. Heated in open vessels, it suddenly becomes red-hot, and, by the absorption of oxygen, changes into antimonious acid, which differs from the teroxide in being insoluble in muriatic acid, less fusible, and not volatile. This oxide is the active ingredient of all the medicinal preparations of antimony. It is frequently impure from containing antimonious acid, in which case it will not be *entirely* soluble in muriatic acid. If it contain terchloride, which it is apt to do from the imperfect action of the alkaline solutions employed in its purification, its solution in tartaric acid will be precipitated by nitrate of silver. When antimonious acid is substituted for it, the fraud may be detected by the spurious preparation being entirely insoluble in muriatic acid. Teroxide of antimony consists of one eq. of antimony 129, and three of oxygen 24=153, and its formula is consequently SbO_3.

Medical Properties. This oxide possesses the general therapeutic properties of the antimonials. It deserves more attention than has been paid to it; and its effects, comparatively with those of tartar emetic, should be carefully studied. It is probable that its sedative operation would be found the same, with less nausea and disturbance of the stomach. Like antimonial powder, it is very unequal in its effects, sometimes vomiting, at other times being apparently inert. In the case of the French Codex oxide, prepared by boiling the oxychloride with a solution of bicarbonate of potassa, these differences are attributed by M. Durand, of Caen, to the presence of more or less terchloride, which is separated with difficulty. Objecting to the Codex oxide, M. Durand proposes to obtain it by precipitating tartar emetic with ammonia in excess. The oxide, thus obtained, contains no terchloride, and does not vomit. (*Journ. de Pharm.*, 3e *sér.*, ii. 364.) The dose of the oxide is from three to ten grains, repeated every two or three hours, and given in powder with syrup or molasses, or in pill made up with confection of roses, or other suitable excipient.

Off. Prep. Antimonium Tartarizatum. B.

ANTIMONII ET POTASSÆ TARTRAS. *U. S.* Antimonii Potassio-tartras. *Lond.* Antimonium Tartarizatum. *Ed., Dub. Tartrate of Antimony and Potassa. Tartarized Antimony. Tartar Emetic.*

"Take of Sulphuret of Antimony, in fine powder, *four ounces;* Muriatic Acid *twenty-five ounces;* Nitric Acid *two drachms;* Water *a gallon.* Having mixed

the Acids together in a glass vessel, add by degrees the Sulphuret of Antimony, and digest the mixture, with a gradually increasing heat, till effervescence ceases; then boil for an hour. Filter the liquor when it has become cold, and pour it into the Water. Wash the precipitated powder frequently with water, till it is entirely freed from acid, and then dry it. Take of this powder *two ounces;* Bitartrate of Potassa, in very fine powder, *two ounces and a half;* Distilled Water *eighteen fluidounces.* Boil the Water in a glass vessel; then add the powders previously mixed together, and boil for an hour; lastly, filter the liquor while hot, and set it aside to crystallize. By further evaporation, the liquor may be made to yield an additional quantity of crystals, which should be purified by a second crystallization." *U. S.*

"Take of Sulphuret of Antimony, in fine powder, *four ounces;* Muriatic Acid (commercial) *a pint* [Imperial measure]; Water *five pints* [Imp. meas.]. Dissolve the Sulphuret in the Acid with the aid of a gentle heat; boil for half an hour; filter; pour the liquid into the Water; collect the precipitate on a calico filter, wash it with cold water till the water ceases to redden litmus paper; dry the precipitate over the vapour-bath. Take of this precipitate *three ounces;* Bitartrate of Potash *four ounces and two drachms;* Water *twenty-seven fluidounces* [Imp. meas.]. Mix the powders, add the Water, boil for an hour, filter, and set the liquid aside to crystallize. The mother-liquor, when concentrated, yields more crystals, but not so free of colour, and, therefore, requiring a second crystallization." *Ed.*

"Take of Oxide of Antimony *five ounces* [avoirdupois]; white Bitartrate of Potash *six ounces* [avoird.]; Distilled Water *one quart* [Imp. meas.]. Rub the Bitartrate to a fine powder, and, having carefully mixed it with the Oxide of Antimony, add a little Water, so as to convert the mixture into a thick paste, which should be set by for twenty-four hours. Pour on this the remainder of the Water, previously raised to the temperature of 212°, and, having boiled for fifteen minutes, with repeated stirring, in a glass or porcelain vessel, filter through calico, returning the slightly turbid liquor which first passes through, so as to obtain a clear solution. After twelve hours let the solution be decanted from the crystals which will have formed, and boiled down to one-third, when, on cooling, an additional product will be obtained. The salt, after being dried upon blotting paper without the application of heat, should be preserved in a bottle." *Dub.*

"Take of Tersulphuret of Antimony, in very fine powder, *a pound;* Sulphuric Acid *fifteen fluidounces* [Imp. meas.]; Bitartrate of Potassa *ten ounces;* Distilled Water *five pints* [Imp. meas.]. Mix the Tersulphuret with the Acid in an iron vessel, and expose the mixture, under a chimney, to a gentle heat, occasionally stirring with an iron spatula. Then increase the heat, until, the flame of burning sulphur having gone out, nothing remains but a whitish pulverulent mass. Wash this, when cold, with water, until all acid is removed, and dry it. Mix thoroughly *nine ounces* of this salt with the Bitartrate, and boil in the Water for half an hour. Strain the liquor while still hot, and set it aside to form crystals. Having poured off the liquor, dry these, and again evaporate that crystals may form." *Lond.*

This preparation is a double salt, consisting of tartrate of potassa, united with tartrate of teroxide of antimony. The principle of its formation is exceedingly simple, being merely the saturation of the excess of acid in the bitartrate (cream of tartar) with the teroxide. The officinal processes all consist in boiling a mixture of cream of tartar and some form of the teroxide with water. The U. S. and Edinburgh Pharmacopœias agree in using the form of teroxide, called *oxychloride of antimony*, or *powder of Algaroth*, which is not officinal under a distinct name, but is formed in the first step of the tartar emetic processes of those works. The Dublin College, in its revised Pharmacopœia of 1850, has

substituted the pure teroxide of antimony for the oxychloride, which, not being now used in any officinal preparation, is expunged from its catalogue. The London College has abandoned the use of the *crocus of antimony*, and employs at present (Pharmacopœia of 1851) the form of teroxide obtained by boiling sulphuric acid with the tersulphuret to dryness, and washing the product.

The *U. S.* and *Edinburgh* Pharmacopœias agree in the same general plan for making the oxychloride. The tersulphuret of antimony is dissolved in from five to six times its weight of muriatic acid, assisted by a hundredth of nitric acid in the U. S. formula, but without this acid in the Edinburgh. The solution is thrown into a large quantity of water, equal to about twenty-five or thirty times the weight of the sulphuret employed, and the oxychloride is precipitated. This is mixed with from one and a quarter to about one and a half times its weight of cream of tartar, and boiled, for from half an hour to an hour, with about eight and a half times its weight of distilled water; and the liquor obtained is filtered while hot and set aside to crystallize. By further evaporation the mother-liquor may be made to yield a second crop of crystals, which, not being free from colour, must be purified by a second crystallization. When no more crystals can be obtained, the liquor which is left contains, according to Knapp, a gummy salt, which consists of tartrate of potassa united to the tertartrate of teroxide of antimony. If this liquor be boiled with a fresh portion of oxychloride, as long as this is taken up, it will furnish an additional quantity of crystals of tartar emetic; and, finally, if the new mother-liquor be saturated with carbonate of potassa, it will furnish a third crop of the antimonial salt, after which the liquor is entirely exhausted. (*Journ. de Pharm.*, xxvi. 136, from *Annal. der Pharm.*) The oxychloride, as its name imports, contains a portion of terchloride. This is decomposed during the boiling, by means of the elements of water, into additional teroxide, which helps to form the tartar emetic, and muriatic acid which serves to hold in solution iron and other metallic impurities, which otherwise would fall and contaminate the crystals. Accordingly, it is asserted that the pure teroxide is not so well fitted for making tartar emetic as the oxychloride, in which the teroxide is usefully combined with some terchloride. If this statement should be confirmed, the Dublin College has injudiciously substituted the pure teroxide for the oxychloride in its last formula for tartar emetic.

In the *London* formula, the teroxide is formed in the following manner. By gently heating sulphuric acid with the tersulphuret of antimony, the metal is teroxidized at the expense of part of the acid, sulphurous acid is evolved, and sulphur set free. By increasing and continuing the heat until dryness is produced, the whole of the sulphurous acid is driven off, the free sulphur is burnt out, and nothing remains but the teroxide, united with sulphuric acid, in the form of the tersulphate of the teroxide of antimony. This, by continued washing, is converted into the anhydrous disulphate of the teroxide ($2SbO_3,SO_3$). (*Phillips.*) The disulphate is then mixed with cream of tartar in the proportion of nine parts in weight to ten, and the mixture boiled with water in the usual manner.

The use of disulphate of antimony in making tartar emetic originated with the late Mr. Phillips as early as the year 1811. He recommended it to be prepared by boiling metallic antimony with twice its weight of sulphuric acid to dryness, and washing the product with water. This method of preparing it was greatly improved by the substitution of the tersulphuret for metallic antimony, as suggested by the late Dr. Babington. The disulphate, made in this way, has been for a long time used in England for preparing tartar emetic, and is now adopted for the same purpose by the London College. The disulphate process is an eligible one, and, at the same time, has the merit of being economical. Mr. Phillips says it affords "a very pure and beautiful salt."

Having given a sketch of the several officinal formulas, it may be useful to

present them in a table. The form of teroxide selected is reduced to the same quantity, and the measures of water in the U. S., London, and Edinburgh Pharmacopœias are converted into the nearest corresponding weights.

AUTHORITY.	Form of Teroxide employed.	Proportion of Teroxide.	Proportion of Cream of Tartar.	Proportion of Water.
London Pharmacopœia.	Disulphate.	4	4·4	44.4
Dublin do.	Teroxide, pure.	4	4.8	32
U. S. do.	Oxychloride.	4	5	34
Edinburgh do.	Do.	4	5.7	33

It is seen by the table that for a given amount of teroxide, the London College orders the least cream of tartar, and the Edinburgh the most. The proportion of water is not very different in the Dublin, U. S. and Edinburgh Pharmacopœias, but is considerably greater in the London.

In judging of the relative eligibility of these processes, several circumstances are to be taken into view. The cream of tartar should not be in excess; as in that case it is apt to crystallize upon cooling with the tartar emetic formed. To avoid such a result it is better to have a slight excess of antimonial oxide. No rule is applicable to the determination of the proper proportion of water, except that it should be sufficient to dissolve the tartar emetic formed. The hot filtration, directed in the U. S. and London Pharmacopœias, may be conveniently performed by means of the tin apparatus, devised by Dr. Hare for filtering liquids at the point of ebullition. (See *page* 773 for a figure of this apparatus.) The U. S. and Edinburgh Pharmacopœias boil for an hour; the London, for half an hour; the Dublin for fifteen minutes. In all cases the salt should be obtained in well defined crystals, unmixed with those of cream of tartar, as the best index of its purity. The practice of some manufacturing chemists of boiling the filtered liquor to dryness, whereby an impure mass is obtained, consisting in part only of the antimonial salt, is very reprehensible.

It is not easy to decide as to the relative eligibility of the different forms of antimonial oxide used for preparing tartar emetic; but it may be proper to state that the preference was given to the oxychloride (*powder of Algaroth*) by Berzelius; and M. Henry, an eminent pharmaceutist of Paris, after a careful comparison of the different processes, declared in favour of the use of this oxide. This testimony in favour of the oxychloride induced the revisers of our national Pharmacopœia in 1830, to adopt it for making tartar emetic; and the Edinburgh College judiciously substituted it for the crocus of antimony in its revision of 1839.

M. Henry has given a process for preparing tartar emetic with the oxychloride on a large scale; and as his formula may be useful to the manufacturing chemist, we subjoin it, turning the French weights into the nearest *apothecaries'* weights and measures. Take of prepared sulphuret of antimony, in very fine powder, three pounds four ounces; muriatic acid, marking 22° (sp. gr. 1·178), eighteen pounds and a half; nitric acid two ounces and a half. Introduce the sulphuret into a glass matrass, of a capacity double the volume of the mixture to be formed; and add to it from three to five pounds of the acids previously mixed, so that the sulphuret may be thoroughly penetrated by them; then add the remainder of the acids. Place the matrass on a sand-bath, and heat the mixture gradually to ebullition, avoiding the vapours, which are disengaged in large quantity. Continue the heat until the vapours given off are so far deprived of sulphuretted hydrogen as not to blacken white paper moistened with solution of acetate of lead; after

which allow the liquor to cool, and to remain at rest until it has become clear. Decant the clear liquor, and, in order to procure the portion of liquid which may be retained by the moist residue, add to this a small portion of muriatic acid, and again decant. Mix the decanted liquids, which consist of a solution of terchloride of antimony, and add them to a large quantity of water, in order that the oxychloride may be precipitated; taking care, during their addition, to stir constantly in order that the precipitated powder may be more minutely divided, to facilitate its subsequent washing. To determine whether the water has been sufficient to decompose the whole of the terchloride, a part of the supernatant liquid, after the subsidence of the powder, is to be added to a fresh portion of water; and, if a precipitate take place, more water must be added to the mixture, so as to obtain the largest possible product of oxychloride. The precipitation being completely effected, wash the powder repeatedly with water, until this no longer affects litmus, and place it on linen to drain for twenty-four hours. The quantity of oxychloride thus obtained will be about three pounds and a half in the moist state, or two pounds nine ounces when dry. Assuming it to be this quantity, mix it with three pounds eleven ounces of cream of tartar, in fine powder, and add the mixture to two gallons and five pints of boiling water, contained in an iron kettle. Concentrate the liquor rapidly until it marks 25° of Baumé's hydrometer for salts, and then filter. By repose the liquor furnishes a crop of very pure crystals, which require only to be dried. The mother waters are treated in the following manner. Saturate the excess of acid with chalk, filter, and concentrate to 25°. By cooling a second crop of crystals will be obtained; and by proceeding in a similar manner, even a third crop. But these crystals are somewhat coloured, and must be purified by recrystallization.

In relation to the above process, it may be observed that the proportion of oxychloride and cream of tartar must be adjusted according to the numbers given, on the assumption that the former is dry; but it by no means follows that the whole of the oxide should be dried. To proceed thus would be a waste of time. The mode of proceeding is to weigh the whole of the moist oxide, and afterwards to weigh off a small part of it, and ascertain how much this loses in drying. Then by a calculation it is easy to determine how much the whole of the moist oxide would weigh in the dry state.

Tartar emetic is not usually prepared by the apothecary, but made on a large scale by the manufacturing chemist. Different processes are pursued in different manufactories; and it is not material what plan is adopted, provided the crystals of the antimonial salt are carefully purified. In an extensive manufactory in London, antimony ash (see *page* 104) is employed for boiling with the cream of tartar, and it is stated to form the cheapest material for making tartar emetic. (*Pereira, Mat. Med.*) Mohr prefers the use of a *moist* oxide, prepared by adding gradually an intimate mixture of one part, each, of tersulphuret of antimony and nitrate of potassa, to a boiling mixture of one part of sulphuric acid and two of water. The liquid is boiled down nearly to dryness and allowed to cool. The grayish-white mass, thus formed, is then washed thoroughly with water. The details of this process are given by Soubeiran, by whom it is praised, in the *Journ. de Pharm.*, 3*e sér.*, iii. 327.

Properties, &c. Tartrate of antimony and potassa was discovered in 1631 by Adrian de Mynsicht. It is in the form of transparent, colourless crystals, which possess a nauseous, metallic, styptic taste, and have usually the form of rhombic octohedrons. When prepared from the oxychloride, it crystallizes in tetrahedrons. As it occurs in the shops it is in the form of a white powder, resulting from the pulverization of the crystals. The crystals, when exposed to the air, effloresce slightly and become white and opaque. They are insoluble in alcohol, but dissolve in proof spirit or wine. (See *Vinum Antimonii.*) They are soluble in about

fifteen parts of water at 60°, and in between two and three parts of boiling water. The late Dr. Perceval, of Dublin, alleged that good tartar emetic dissolves in twelve parts of water, and this statement agrees nearly with the results of Brandes, who found it to be soluble in 12·65 parts of water at 70°. Its aqueous solution slightly reddens litmus, and undergoes decomposition by keeping. It is incompatible with acids, with alkalies and their carbonates, with some of the earths and metals, with chloride of calcium, and with acetate and subacetate of lead. It is incompatible also with astringent vegetable infusions and decoctions, such as of rhubarb, cinchona, catechu, galls, &c.; but these substances, unless galls be an exception, do not render it inert, though they lessen its activity to a greater or less extent.

Characteristics and Tests of Purity. Tartar emetic, when pure, exhibits its appropriate crystalline form. A crystal or two, dropped into a solution of hydrosulphuric acid, will be covered with an orange-coloured deposit of tersulphuret of antimony. One hundred grains of the salt dissolved in water, yield forty-nine grains of tersulphuret with this test. (*Lond. Pharm.*, 1851.) Entire solubility in water is not a character belonging exclusively to the pure salt; for, according to the late Mr. Hennell, tartar emetic may contain ten per cent. of uncombined cream of tartar, and yet be wholly soluble in the proper proportion of water. (*Phillips.*) This being the case, the character, given in the U. S. and Edinburgh Pharmacopœias, of entire solubility in twenty parts of water, is not to be depended upon. A dilute solution is not precipitated by chloride of barium or nitrate of silver, nor rendered blue by ferrocyanuret of potassium. A solution, containing one part of tartar emetic in forty of water, is not disturbed by an equal volume of a solution of eight parts of acetate of lead in thirty-two of water and fifteen of acetic acid. This test is adopted in the U. S. Pharmacopœia from the Edinburgh, and is intended to show the absence of uncombined bitartrate of potassa; for when the acidulated acetate is used as here directed, it does not form the white tartrate of lead with the pure antimonial salt, but only with the bitartrate, when this happens to be present. The acidulated acetate is a delicate test of this impurity, capable of detecting one per cent. of it in tartar emetic; but Dr. Christison finds difficulties in using it which render it too precarious for practice. Mr. Hennell's method of detecting uncombined bitartrate, is to add a few drops of a solution of carbonate of soda to a boiling solution of the antimonial salt. If the precipitate formed is not redissolved, no bitartrate is present.

The impurities found in tartar emetic are uncombined cream of tartar from faulty preparation or fraudulent admixture, tartrate of lime, iron, sulphates, and chlorides. The mode of detecting cream of tartar has been indicated above. Tartrate of lime is derived from the cream of tartar, which always contains this impurity. It is apt to form on the surface of the crystals of tartar emetic in crystalline tufts, which are easily brushed off. Iron is sometimes present, especially when the antimonial salt has been prepared from glass of antimony. It is detected by a blue colour being *immediately* produced by ferrocyanuret of potassium, added after a little acetic acid. If the blue colour be *slowly* produced, it may arise from reactions on the iron of the ferrocyanuret itself. If much iron be present, the solution of the tartar emetic will be yellow instead of colourless. Sulphates are detected by chloride of barium The presence of a chloride is shown by a precipitate being produced by nitrate of silver, added to a dilute solution. According to Serullas, tartar emetic, except when well crystallized, and all the other antimonial preparations usually contain a minute proportion of arsenic, derived from the native tersulphuret of antimony, which almost always contains this dangerous metal. (For the mode of detecting it, see *Acidum Arseniosum.*) Tartar emetic is sometimes sold in powder to conceal its imper-

fections. It should never be bought in this state by the apothecary, but always in crystals, in which state the salt is pure, or very nearly so, and entirely free from arsenic. Its powder is perfectly white, and when yellowish-white, iron is probably present. It is said that some druggists ignorantly prefer a tartar emetic which is yellowish-white in powder.

It has been already stated, in general terms, that tartar emetic in solution is incompatible with acids and alkalies, and with some of the earths; but this salt is so important, that some details in regard to the effects of particular reagents, included under these titles, seem to be necessary. Muriatic and sulphuric acids, added to a solution of the antimonial salt, not too dilute, throw down a white precipitate of subchloride or subsulphate of antimony, mixed with cream of tartar, which is redissolved by an excess of the precipitant. Nitric acid throws down a subnitrate, which is taken up by an excess of it. This effect of nitric acid is given by the London College as a character of good tartar emetic, but is certainly not very distinctive. When caustic potassa is added to a tolerably concentrated solution of the antimonial salt, it produces at first no effect, then a precipitate of teroxide, and afterwards the solution of this precipitate, if the addition of the alkali be continued. Lime-water acts in a weaker solution, and throws down a white precipitate, consisting of the mixed tartrates of lime and antimony. Carbonate of potassa affects still weaker solutions, throwing down a white precipitate of teroxide; but this test does not act in solutions containing less than a quarter of a grain of the antimonial salt to the fluidounce. Ammonia, both pure and carbonated, precipitates a solution of tartar emetic, throwing down the pure teroxide. Dr. Barker, of Dublin, has proposed the carbonate of ammonia as a precipitant for obtaining the oxide, when wanted as a medicine. (See *page* 867.) To these reagents may be added the infusion of galls, which, when fresh and strong, causes a dirty, yellowish-white precipitate of tannate of the teroxide of antimony.

Composition. Tartar emetic consists of two eqs. of tartaric acid 132, one of potassa 47·2, one of teroxide of antimony 153, and three of water 27=359·2. It is evident that it contains tartaric acid and potassa in the precise proportion to form bitartrate of potassa or cream of tartar; and, accordingly, it may be viewed as a compound of one eq. of cream of tartar, and one of antimonial teroxide. The excess of acid in the bitartrate may be considered as united with the teroxide; and on that view it is a double salt, composed of the tartrate of potassa, united with the tartrate of teroxide of antimony. The name, therefore, of the U. S. Pharmacopœia is correct.

Medical Properties and Uses. Tartrate of antimony and potassa is the most important of the antimonials, and is capable of fulfilling numerous indications in disease. Its general action is that of a sedative upon the circulation; while, on the contrary, it excites most of the secretions. According to the dose, and the peculiar circumstances under which it is administered, it acts variously as an alterative, diaphoretic, diuretic, expectorant, purgative, and emetic. In minute doses it is employed, either alone or conjoined with calomel, with a view to its alterative effects, and has been found useful in diseases of the skin. In small doses, mostly associated with saline remedies, such as nitre or sulphate of magnesia, and assisted by copious dilution, it is frequently resorted to in febrile complaints, for the purpose of producing perspiration, which is often copiously induced, especially if the remedy gives rise to nausea. If the surface be exposed to cool air, so as to constrict the pores, the tendency will be to the kidneys, with the effect of producing an increased flow of urine. On the principle of exciting the secretions, it proves useful, on many occasions, in pulmonary and bronchial disease as an expectorant; and with a view to its action in this way, it is frequently conjoined with squill, ammoniac, and similar remedies. In full

doses it acts as an emetic, and as such is characterized by certainty, strength, and permanency of operation. It remains longer in the stomach than ipecacuanha, produces more frequent and longer continued efforts to vomit, and exerts a more powerful impression upon the system generally. The nausea and attendant prostration are often very considerable. As an emetic, its use is indicated where the object is not merely to evacuate the stomach, but to agitate and compress the liver and other abdominal viscera. By the extension of its action to the duodenum, it often causes copious discharges of bile, and hence forms an appropriate remedy in those diseases in which there is an accumulation of that secretion. It is employed as an emetic in the commencement of fevers, especially those of an intermittent or bilious character; in jaundice, hooping-cough, and croup; and in several diseases of the nervous system, such as mania, amaurosis, tic douloureux, &c. In efforts to reduce old dislocations, its relaxing power over the muscles, when acting as a nauseant, is taken advantage of, in order to facilitate the operation. As an incidental effect to its diaphoretic and emetic operation, tartar emetic often produces purging. Taking advantage of this tendency, practitioners are frequently in the habit of adding it to purgatives, the operation of which it promotes in a remarkable degree. It is contra-indicated in diseases of great debility, in the advanced stages of febrile affections, and in fevers attended with irritability of stomach.

Of late years, on the continent of Europe, and to a certain extent in Great Britain and this country, tartar emetic has been given in large doses, with a view to its sedative, or, as it is usually termed, *controstimulant* operation. This practice originated with Rasori, professor of clinical medicine at Milan, who published his views in 1800. The principal diseases in which it has been thus used, are pneumonia, pleurisy, bronchitis, acute rheumatism, especially of the joints, articular dropsies, chorea, hydrocephalus, and apoplexy. The medicine is directed in doses, varying from a grain to two grains or more, every two hours, dissolved in a small quantity of water; the patient being restricted in the use of drinks whilst under its operation. It is stated that when the remedy is thus given in diseases of high action, it seldom produces vomiting, an effect which the authors of the practice wish to avoid. The power of the system to bear large doses of tartar emetic, during the existence of acute disease, was considered by Rasori to depend upon the coexistent high morbid excitement, and the capability of bearing them was expressed by the term *tolerance*. It is in pneumonia especially that the controstimulant practice has most advocates. It is admitted to have the effect of lowering the force and frequency of the pulse, and the rapidity of the respirations; and, in not a few instances, it produces marked remedial effects. In pleurisy and bronchitis, the advantages of the same practice are less decided. Though we are disposed to admit the controlling influence of tartar emetic, when thus exhibited, in the diseases named; yet we by no means think that its use should supersede bloodletting, or even form our chief reliance. In cases, however, in which bloodletting, both general and local, has no effect, or has been carried as far as the circumstances of the case will warrant, tartar emetic, administered on the controstimulant plan, may be found useful. If the tolerance cannot be otherwise established, laudanum may be conjoined with the antimony, in order to bring it about. In the treatment of articular dropsies, the decided benefit derived from large doses of tartar emetic is fully shown by M. Gimelle, who has reported twenty-eight successful cases in support of the practice. The medicine was gradually increased from four grains to sixteen or twenty daily, and, generally, the tolerance was established on the first day. The effusion was absorbed in a space of time varying from eight to sixteen days. M. Vidart has used large doses of tartar emetic, associated with laudanum, with good effect, in a case of delirium tremens. (*Journ. de Pharm. et de Chim.*, April, 1851.)

Externally, tartar emetic is sometimes employed as a counter-irritant, mixed with lard or cerate, or sprinkled in very fine powder on adhesive plaster. (See *Unguentum Antimonii.*) It causes, after a longer or shorter interval, a burning sensation, accompanied by a peculiar and painful pustular eruption. This mode of producing counter-irritation is serviceable in a number of diseases; but particularly in deep-seated pains, spinal irritation, hooping-cough, and chronic inflammation of the chest threatening consumption. Care must be taken, when the salt is applied by means of a plaster, that the pustular inflammation does not proceed too far; as, in that event, it produces deep and very painful ulcerations, difficult to heal. According to M. Guerin, inflamed parts exhibit a condition of tolerance to the local effects of tartar emetic, evinced by the absence of pustulation. In support of this view, he asserts that he has treated hundreds of cases of acute arthralgia with tartar emetic ointment with the best effects, mostly without the production of any eruption; and when the pustules were produced, the benefit accrued before they appeared. When no pustulation follows, M. Guerin supposes that the antimony acts by absorption.

Tartar emetic is generally given in solution, and in an amount which varies with the intention in view in its administration. Its dose as an alterative is from the thirtieth to the twelfth of a grain; as a diaphoretic or expectorant, from the twelfth to the sixth of a grain; and as a nauseating sudorific, from a quarter to half a grain; in each case, repeated every hour, two, or four hours. If required to act as a purgative, a grain may be dissolved in half a pint of water with an ounce of Epsom salt, and two tablespoonfuls of the solution given every two or three hours. As an emetic the full dose is from two to three grains; though it is usually given in divided portions of a grain, dissolved in a tablespoonful of water, every ten or fifteen minutes till it vomits; the operation being aided by warm water, or warm chamomile tea. It is often conjoined with ipecacuanha, in the proportion of one or two grains to twenty of that emetic. For convenient administration in small doses, the Pharmacopœias order it dissolved in wine. (See *Vinum Antimonii.*) It is given very conveniently to children in dilute aqueous solution, which, being nearly tasteless, is readily taken by them. In all cases this medicine should be given with caution; as, in some peculiar constitutions, it acts in small doses with unexpected violence.

Effects as a Poison. The effects produced by a poisonous dose of tartar emetic are an austere metallic taste; nausea; copious vomiting; frequent hiccough; burning pain in the stomach; colic; frequent stools and tenesmus; fainting; small, contracted, and accelerated pulse; coldness of the skin; sometimes intense heat; difficult respiration; loss of sense; convulsive movements; very painful cramps in the legs; prostration and death. To these effects is sometimes added difficulty of deglutition. Vomiting and purging in a few instances do not take place; and when they are absent, the other symptoms are aggravated. A case of poisoning by tartar emetic is reported by Dr. J. T. Gleaves, of Tennessee, in which a pustular eruption, like that caused by the external application of the antimonial, was copiously produced. (*Amer. Journ. of Med. Sci.*, xv. 573, from the *Western. Journ. of Med. and Surg.*) These are the effects produced on the healthy economy; but it has been fully proved that the doses which, in a state of health would prove fatal, are sometimes borne with safety in certain morbid states of the system, attended with internal acute inflammation.

In treating a case of poisoning by tartar emetic, if it is found that the patient has not vomited, immediate recourse must be had to tickling the throat with a feather, and the use of abundance of warm water. Usually, however, the vomiting is excessive and distressing, and here it is necessary to use remedies calculated to decompose the poison, and to allay the pain and irritation. To effect the former object, astringent decoctions and infusions, such as of bark and common

tea, are recommended as antidotes. These, however, act but imperfectly, according to the experiments of M. Toulmouche, who found that a decoction of cinchona had usually no power in lessening the emetic effect of this antimonial. Similar observations have been made by Dr. Clutterbuck. (*Pereira.*) The decoction of galls acts more decidedly; but M. Toulmouche accords the preference to the galls, given in substance, as an antidote in poisoning by tartar emetic. A case of accidental poisoning with half an ounce of tartar emetic, successfully treated with copious draughts of green tea and large doses of tannin, is reported by Dr. S. A. McCreery, U. S. Navy. (*Am. Journ. of Med. Sci.*, Jan. 1853, p. 131.) Galls no doubt act by the tannin they contain, which forms, with the antimonial part of the salt, the insoluble and probably inert tannate of antimony. To stop the vomiting and relieve pain, laudanum should be given, either by the mouth or injection, and to combat consecutive inflammation, bleeding, both local and general, and other antiphlogistic measures should be resorted to.

After death from suspected poisoning by tartar emetic, it is necessary to search for the poison in the body. The substances in the stomach should be digested in water, acidulated with a little muriatic and tartaric acids. The former acid will serve to coagulate some organic matter; the latter to give complete solubility to the antimony. The solution obtained, after having been filtered, is subjected to a stream of sulphuretted hydrogen, which will throw down the orange-red tersulphuret of antimony, distinguishable from the tersulphuret of arsenic, and all other precipitates, by its forming with hot muriatic acid a solution, from which, when added to water, a white curdy precipitate of oxychloride of antimony is thrown down. Sulphuretted hydrogen is by far the most delicate test for tartar emetic.

Sometimes the antimony cannot be found in the stomach and bowels, and yet may exist in other parts. When it leaves the alimentary canal, it has been found by Orfila especially in the liver and kidneys and their secretions. The mode of extracting the antimony, recommended by Orfila, is to carbonize the dried viscera with pure concentrated nitric acid in a porcelain capsule, to boil the charred mass obtained for half an hour with muriatic acid, assisted with a few drops of nitric acid, to filter the liquor, and introduce it into Marsh's apparatus. Antimoniuretted hydrogen will be formed, which, being inflamed, will deposit the antimony on a cold surface of porcelain, as a black stain, distinguishable from the similar stain produced by arsenic by its less volatility, and by its forming with hot muriatic acid a solution which affords a white precipitate when added to water. (See *Arch. Gén.*, 3*e sér.*, vii. 511.)

"Take of Tartrate of Antimony and Potassa *a scruple;* White Wine [Sherry] *ten fluidounces.* Dissolve the Tartrate of Antimony and Posassa in the Wine." *U. S.*

The *London* and *Edinburgh Colleges* direct *two scruples* of the salt [crystals, *Lond.*] to be dissolved in *a pint* [Imperial measure] of Sherry Wine. The *Dublin College* dissolves *a drachm* [54·68 grains] of the salt in *a pint* [Imperial measure] of distilled water, and adds *seven fluidounces* of Rectified Spirit.

In the first edition of the United States Pharmacopœia, the proportion of tartar emetic was four grains to the fluidounce of wine. In the revision of 1830, the quantity was reduced to two grains, and, as this is very nearly the proportion directed by the British Colleges, the highly important object has been accom-

plished, of uniformity in the strength of this very popular preparation. The seeming discrepancy between the London and Edinburgh formulæ, and that of the U. S. Pharmacopœia will disappear, when it is considered that the Imperial pint, adopted by the two British Colleges, contains twenty fluidounces, each very nearly equal to the fluidounce of the ordinary apothecaries' measure. The U. S. officinal name was adopted as most convenient, sufficiently expressive, and in accordance with the nomenclature of several other metallic preparations, such as *Emplastrum Ferri, Mistura Ferri Composita, &c.*

Difficulty is often experienced in effecting a solution of tartar emetic in wine; and precipitation is apt to occur after the solution has been effected. These results are attributable either to impurity in the antimonial salt, which frequently contains bitartrate of potassa and various insoluble substances, or to inferiority in the character of the wine, which holds in solution vegetable principles that form insoluble compounds with the teroxide of antimony. Dr. Paris states that he has seen the decomposition of the tartar emetic so complete, that no traces of the salt could be detected in the supernatant liquid. The difficulty is not avoided by the plan, at one time directed, of first dissolving the antimonial in water, and then adding the wine; for, even allowing that the solution may be accomplished, the same ingredients are present, and their mutual reaction must ultimately result in the same effects. The proper course is to select perfectly pure crystallized tartar emetic, and sound Sherry or Teneriffe wine, which make a permanent solution. To obviate the risk of decomposition, the Dublin College directs water and rectified spirit in about the proportion in which these exist in the wines just mentioned. The only objection to this menstruum is the want of colour, which renders the preparation liable to be confounded with less active liquids.

The advantages of antimonial wine are, that it affords the means of administering minute doses of tartar emetic, and is more permanent than an aqueous solution of that salt, which is liable to spontaneous decomposition. It is usually administered in small doses as a diaphoretic or expectorant, or as an emetic in infantile cases. Where a considerable quantity of tartar emetic is requisite, it should always be given in extemporaneous aqueous solution. The dose of the wine, as an expectorant or diaphoretic, is from ten to thirty drops, given frequently; as an emetic for children, from thirty drops to a fluidrachm, repeated every fifteen minutes till it operates.

ANTIMONII SULPHURETUM PRÆPARATUM. *Dub. Prepared Sulphuret of Antimony.*

"Take of Sulphuret of Antimony of Commerce *any convenient quantity.* Let this be reduced to powder, and the finer particles having been separated from the coarser by the method explained in the formula for *Creta Præparata*, let them be dried, and preserved for use." *Dub.*

Sulphuret of antimony in mass is placed in the Materia Medica list of all the Pharmacopœias noticed in this work. But for use in medicine, and for some pharmaceutical processes, it requires to be in powder, and the above process is intended to bring it to that state. But it is hardly necessary to have a distinct formula to indicate the mode of proceeding, and accordingly this preparation is not included in the U. S., London, and Edinburgh Pharmacopœias.

Properties. Prepared sulphuret of antimony is in the form of an insoluble powder, without taste or smell, usually of a dull blackish colour, but reddish-brown, when perfectly pure. By exposure to the air, it absorbs, according to Buchner, a portion of oxygen, and becomes partially converted into teroxide. Its impurities and composition are mentioned under another head. (See *Antimonii Sulphuretum.*)

Medical Properties and Uses. This preparation is very uncertain in its operation; being sometimes without effect, at other times, if it meets with acid in the stomach, operating with extreme violence by vomiting and purging. The effects usually attributed to it are those of a diaphoretic and alterative; and the diseases in which it has been principally used, are scrofula, glandular obstructions, cutaneous diseases, and chronic rheumatism. It is not employed by physicians in the United States, its use in this country being exclusively confined to veterinary practice. The dose is from ten to thirty grains, given in powder or bolus.

ANTIMONII SULPHURETUM PRÆCIPITATUM. *U.S.*, *Dub.* Antimonii Oxysulphuretum. *Lond.* Antimonii Sulphuretum Aureum. *Ed.* *Precipitated Sulphuret of Antimony. Oxysulphuret of Antimony.*

"Take of Sulphuret of Antimony, in fine powder, *six ounces;* Solution of Potassa *four pints;* Distilled Water, Diluted Sulphuric Acid, each, *a sufficient quantity.* Mix the Sulphuret of Antimony with the Solution of Potassa and twelve pints of Distilled Water, and boil them over a gentle fire, for two hours, constantly stirring, and occasionally adding Distilled Water, so as to preserve the same measure. Strain the liquor immediately through a double linen cloth, and drop into it, while yet hot, Diluted Sulphuric Acid so long as it produces a precipitate; then wash away the sulphate of potassa with hot water, dry the Precipitated Sulphuret of Antimony, and rub it into a fine powder." *U. S.*

"Take of Tersulphuret of Antimony, powdered, *seven ounces;* Solution of Soda *four pints* [Imp. meas.]; Distilled Water *two gallons* [Imp. meas.]; Diluted Sulphuric Acid *a sufficient quantity.* Mix the Tersulphuret and Soda with the Water, and boil with a slow fire for two hours, frequently stirring, Distilled Water being often added, so that the mixture may fill about the same measure. Strain the liquor, and gradually drop into it as much of the Acid as may be sufficient to throw down the Oxysulphuret of Antimony; then wash away the sulphate of soda with water, and dry what remains with a gentle heat." *Lond.*

"Take of Sulphuret of Antimony, in fine powder, *an ounce;* Solution of Potash *eleven fluidounces* [Imp. meas.]; Water *two pints* [Imp. meas.]. Mix the Water and Solution of Potash, add the Sulphuret, boil for an hour, filter immediately, and precipitate the liquid, while hot, with an excess of Diluted Sulphuric Acid. Collect the precipitate on a calico filter, wash it thoroughly with water, and dry it with a gentle heat." *Ed.*

"Take of Prepared Sulphuret of Antimony *five ounces* [avoirdupois]; Carbonate of Potash from Pearlash, first dried at a low red heat, and reduced to powder, *four ounces* [avoird.]; Water *one gallon* [Imp. meas.]; Pure Sulphuric Acid *two fluidounces* [Imp. meas.]; Distilled Water *one quart* [Imp. meas.]. Mix the Sulphuret of Antimony and Carbonate of Potash in a mortar, and heat the mixture in a Hessian crucible, first cautiously until effervescence ceases, and then to low redness, so as to produce liquefaction. Pour out the melted mass on a clean flag, and, when it has concreted and cooled, rub it to a fine powder in a porcelain mortar. Add this, in successive portions, to the gallon of Water while boiling in an iron vessel, and, having maintained the ebullition for twenty minutes, transfer the whole to a calico filter, and cause the solution which passes through to drop into the Distilled Water, previously mixed with the Sulphuric Acid. Let the precipitate which forms be collected on a calico filter, and let warm distilled water be repeatedly poured upon it, until the liquid which passes through ceases to give a precipitate when dropped into a solution of nitrate of barytes. Finally, dry the product on porous bricks, placed in a warm atmosphere." *Dub.*

As the theory of the formation of the precipitated sulphuret of antimony is intimately connected with that of the production of the substances called *kermes mineral* and *golden sulphur*, we shall first describe the latter preparations as introductory to our account of the former.

Kermes mineral, according to Thenard, may be obtained by treating the tersulphuret of antimony in three ways; 1st with a boiling solution of the carbonated alkalies, 2d with a boiling solution of the caustic alkalies, and 3d with the carbonated alkalies at a red heat. These several processes give brown powders, which vary in their shade of colour, and which, though usually considered as identical, differ in composition. The kermes obtained by means of the carbonated alkalies in solution is an oxysulphuret, that is, a mixture of teroxide of antimony with hydrated tersulphuret; while the product, when either the caustic alkalies in solution, or the carbonated alkalies at a red heat are used, is essentially a hydrated tersulphuret, though containing occasionally a little oxysulphuret.

In France the process by the use of the carbonated alkalies in solution is preferred for preparing kermes; and the alkali selected is soda as giving a handsomer product. The formula of Cluzel is to boil for half an hour one part of pulverized tersulphuret of antimony with twenty-two or twenty-three parts of crystallized carbonate of soda, in two hundred and fifty parts of water, to filter the liquor, and receive it in warm earthen pans, which must be covered, and allowed to cool slowly. At the end of twenty-four hours, the kermes is deposited. It is then collected on a filter, washed with *boiled* water cooled without contact of air, dried at the temperature of 77°, and kept in bottles well stopped. This formula is substantially the same with that given in the French Codex of 1837.

The rationale of the formation of kermes by this process is as follows. A portion of the carbonate of soda is converted, by a transfer of carbonic acid, into caustic soda and sesquicarbonate. By a double decomposition taking place between a part of the tersulphuret of antimony and the caustic soda, teroxide of antimony and sulphuret of sodium are formed. The teroxide then dissolves in the solution of the remaining carbonate of soda, and the undecomposed portion of the tersulphuret in that of the sulphuret of sodium. The teroxide and tersulphuret being both more soluble in these menstrua hot than cold, precipitate together as the liquid cools, and constitute this variety of kermes. When thus obtained, it is light, velvety, of a dark reddish-purple colour, brilliant in the sun, and of a crystalline appearance. It consists, according to M. Henry, jun., of tersulphuret of antimony 62·5, teroxide 27·4, water 10, and soda a trace: proportions which correspond most nearly with two eqs. of tersulphuret, one of teroxide, and six of water. In consequence of the presence of a considerable amount of teroxide of antimony in this variety of kermes, it must be far more active than the other kinds, and ought, therefore, to be preferred for medicinal use.

Kermes, when obtained by means of the caustic alkalies, may be formed by the use of either potassa or soda. When the former alkali is selected, it may be prepared by boiling for a quarter of an hour, two parts of the tersulphuret of antimony with one part of caustic potassa dissolved in twenty-five or thirty parts of water, filtering the liquor, and allowing it to cool; whereupon the kermes precipitates. In this process, one portion of the tersulphuret, by reacting with a portion of the potassa, gives rise to teroxide of antimony and sulphuret of potassium. A second portion dissolves in the solution of sulphuret of potassium formed, and a third forms an insoluble compound with a part of the teroxide. The remainder of the teroxide unites with the undecomposed potassa, forming a compound, which, being but sparingly soluble, is only in part dissolved. The hot filtered liquor, therefore, contains this compound dissolved in water, and tersulphuret of antimony dissolved in the solution of sulphuret of potassium. By refrigeration, the tersulphuret in a hydrated state falls down,

free or nearly free from teroxide, this latter being still held in solution by means of the caustic alkali with which it is united.

Kermes is obtained by the third method, that is, in the dry way, by rubbing together two parts of tersulphuret of antimony and one of carbonate of potassa, fusing the mixture in a crucible by a red heat, reducing the fused mass to powder, boiling it with water, and straining. As the strained liquor cools the kermes is deposited. The rationale of its formation is nearly the same with that of the formation of the second variety of kermes. An inferior kermes, prepared in the dry way, and intended for use in veterinary medicine, is directed in the French Codex to be prepared by fusing together, well mixed, 500 parts of tersulphuret of antimony, 1000 of carbonate of potassa, and 30 of washed sulphur, reducing the fused mass to powder, and boiling it with 10,000 parts of water. The liquor, upon cooling, lets fall the kermes, which must be washed with care and dried.

Kermes mineral is an insipid, inodorous powder, of different shades of brown. By the action of air and light it gradually becomes lighter coloured, and at last yellowish-white. It is sometimes adulterated with sesquioxide of iron. In Paris, in 1849, a number of the shops contained a spurious kermes of very handsome appearance, which was little else than this oxide. (*Journ. de Pharm.*, Oct. 1849.) Kermes mineral first came into use as a remedy in France about the beginning of the last century. Its mode of preparation was possessed as a secret by a French surgeon named La Ligerie. In 1720, the recipe was purchased by the French government and made public.

Golden sulphur is formed by the addition of an acid to the liquor which remains after the precipitation of the kermes. According to the directions of the French Codex, acetic acid is employed for this purpose. The liquor, when caustic potassa has been used, consists *at first* chiefly of tersulphuret of antimony dissolved in solution of sulphuret of potassium, but in part also of teroxide, dissolved in solution of potassa. By the action of the oxygen of the air on the liquor, however, the sulphuret of potassium has part of its potassium gradually converted into potassa, and thus passes to a higher state of sulphuration; and, consequently, the addition of an acid, while it throws down the tersulphuret and teroxide of antimony with disengagement of sulphuretted hydrogen, will precipitate at the same time the excess of sulphur which the sulphuret of potassium has gained. Agreeably to this explanation, golden sulphur is a mixture of tersulphuret and teroxide of antimony, containing more or less free sulphur. It is in the form of a powder of a golden-yellow colour. As it is partially decomposed by light, it should be kept in opaque vessels. It may be worth while to mention that the kermes liquor, left after the use of the carbonated alkalies in solution, gives but little golden sulphur; while the liquors, resulting from the two other processes, yield it in abundance.

From the explanations above given, the reader is prepared to understand that the method of preparing the precipitated sulphuret of antimony of the U. S., London, and Edinburgh Pharmacopœias, combines the process for forming the kermes mineral by means of a *caustic alkali*, with that for obtaining golden sulphur; for, while the refrigeration of the solution acting alone would cause the precipitation of the variety of kermes, which contains little or no antimonial oxide, the sulphuric acid added would throw down more or less of the golden sulphur. But the question here arises how far this golden sulphur would be identical with that obtained from the mother liquor of kermes which has been kept for some time. From the explanations above given in relation to golden sulphur, it may be inferred as probable that the precipitate by acids, if thrown down immediately, while the solution is hot, as directed by the Pharmacopœias, and before the air has had time to act, would consist exclusively of tersulphuret

and teroxide; but, if thrown down from the kermes mother liquor, would contain more or less free sulphur, according as the liquor had been more or less subject to the influence of the air. If these views be admitted, it follows that the so-called golden sulphur must be a variable preparation as to the free sulphur it contains, dependent upon the greater or less change which the kermes liquor may have undergone before being used for furnishing the precipitate.

Formerly, all the Pharmacopœias noticed in this work used a solution of caustic potassa in preparing precipitated sulphuret of antimony; but at present the London College employs a solution of caustic soda, and the Dublin, carbonate of potassa in the dry way. These changes were made in the recently revised Pharmacopœias of those Colleges. The use of soda does not alter the theory of the process. The Dublin College, in the use of carbonate of potassa, proceeds, at first, precisely as if kermes by the third method was to be obtained (see *page* 880); but, instead of collecting the strained liquor in an empty vessel, allows it to drop into water, acidulated with sulphuric acid.

Properties of the Precipitated Sulphuret of Antimony. This substance is a reddish-brown insoluble powder, tasteless when pure, but having usually a slightly styptic taste. When treated with twelve times its weight of muriatic acid of the sp. gr. 1·16, with the aid of heat, it is nearly all dissolved, with effervescence of sulphuretted hydrogen. The residue burns with the characters of sulphur, and leaves a scanty ash. The solution obtained, when added to water, is decomposed, giving rise to a white powder of oxychloride of antimony (powder of Algaroth). The solution, filtered from the powder, yields an orange-red, precipitate with hydrosulphate of ammonia, proving the presence of a small quantity of antimony, not thrown down by the water. A dark-coloured precipitate, produced by this test, shows the presence of contaminating metals, probably lead and copper. Water in which this preparation has been boiled, should not yield a white precipitate with chloride of barium or oxalate of ammonia. The non-action of these tests shows the absence of sulphuric acid and lime. When pure, precipitated sulphuret of antimony is completely soluble in a hot solution of potassa, but as it is found in the shops, a white matter is usually left undissolved. When boiled with a solution of cream of tartar, about 12 per cent. of teroxide is dissolved; but, according to H. Rose, this method of determining the proportion of the teroxide cannot be relied on. Exposed to heat it takes fire, burning with a greenish-blue flame and giving off sulphurous acid, while the metal remains behind in the state of a grayish oxide.

The London precipitated sulphuret of antimony, as analyzed by Mr. Phillips, consists, in the 100 parts, of tersulphuret 76·5, teroxide 12, and water 11·5; proportions corresponding nearly with five eqs. of tersulphuret, one of teroxide, and fifteen of water. It usually contains a portion of free sulphur, as shown by the action of muriatic acid. Its active ingredient is the teroxide; and, in reference to its presence, the London College calls the preparation *oxysulphuret of antimony*. The Edinburgh College names it incorrectly *golden sulphuret of antimony;* this name being properly applicable to the precipitate produced by the sole action of acids, and not to that obtained by the action of acids and refrigeration conjointly.

Medical Properties. The precipitated sulphuret of antimony is alterative, diaphoretic, and emetic. It is, however, an uncertain medicine, as well from the want of uniformity in its composition, as from its liability to vary in its action with the state of the stomach. It is seldom given alone, but generally in combination with calomel and guaiac, in the form of Plummer's pill, as an alterative in secondary syphilis and cutaneous eruptions, or conjoined with henbane or hemlock in chronic rheumatism. (See *Pilulæ Calomelanos Compositæ.*) During its use the patient should abstain from acidulous drinks. Its dose as an

alterative is from one to two grains twice a day, in the form of pill; as an emetic, from five grains to a scruple. The kermes, obtained by means of the carbonated alkalies in the moist way, as it contains between two and three times as much teroxide as the precipitated sulphuret, is a more active preparation, and must be used in a smaller dose. Kermes mineral is sometimes given in large doses as an antiphlogistic remedy in peripneumony and other inflammations of the chest.

Off. Prep. Pilulæ Calomelanos Compositæ. B.

PULVIS ANTIMONIALIS. *Ed., Dub.* PULVIS ANTIMONII COMPOSITUS. *Lond. Antimonial Powder. Compound Powder of Antimony.*

"Take of Tersulphuret of Antimony, powdered, *a pound;* Horn shavings *two pounds.* Mix, and throw them into a red-hot crucible, and stir constantly until vapour ceases to arise. Rub the residue to powder, and put it into a crucible. Then apply heat, and raise it gradually to redness, and keep it so for two hours. Rub the remaining powder until it is as fine as possible." *Lond.*

"Take of Sulphuret of Antimony, in coarse powder, Hartshorn shavings, *equal weights.* Mix them, put them into a red-hot iron pot, and stir constantly till they acquire an ash-gray colour, and vapours no longer arise. Pulverize the product, put it into a crucible with a perforated cover, and expose this to a gradually increasing heat till a white heat is produced, which is to be maintained for two hours. Reduce the product, when cold, to fine powder." *Ed.*

"Take of Tartarized Antimony, Phosphate of Soda, each, *four ounces* [avoirdupois]; Chloride of Calcium *two ounces* [avoird.]; Solution of Ammonia *four fluidounces* [Imp. meas.]; Distilled Water *one gallon and a half* [Imp. meas.], or *a sufficient quantity.* Dissolve the Tartarized Antimony in half a gallon, and the Phosphate of Soda and Chloride of Calcium, each, in a quart of the Water. Mix the solutions of the Tartarized Antimony and Phosphate of Soda when cold, and then pour in the solution of Chloride of Calcium, having first added to the latter the Water of Ammonia. Boil now for twenty minutes, and, having collected the precipitate, which will have then formed, on a calico filter, wash it with hot distilled water until the liquid which passes through ceases to give a precipitate with a dilute solution of nitrate of silver. Finally, dry the product by a steam or water heat, and reduce it to a fine powder." *Dub.*

This preparation, made according to the London and Edinburgh formulæ, consists mainly of bone-phosphate of lime, or calcined bone, mixed with antimonious acid, and is intended to furnish a substitute for the celebrated nostrum of Dr. James, an English physician who died in 1776, and after whom the original composition was called *James's powder.* Dr. Pearson, of London, found the genuine powder, on analysis, to consist of phosphate of lime and oxidized antimony, and, guided by his results, devised the formula adopted by the London and Edinburgh Colleges. By burning the materials directed by these Colleges, the sulphur is expelled in the form of sulphurous acid, and the antimony oxidized; while the horn, which is of the nature of bone, has its animal matter converted into charcoal. By the subsequent calcination, the charcoal is dissipated, leaving only the phosphate of lime mixed with the oxidized antimony. This mixture constitutes the antimonial powder. The only material difference between the processes is that the London College uses two parts of horn shavings to one of sulphuret; while the Edinburgh employs equal weights, which are also the proportions adopted in the French Codex. The use of the larger proportion of horn is said to obviate the inconvenience of the vitrification of part of the antimony; but the late Dr. Duncan alleged that the product thus obtained does not correspond so well with James's powder as analyzed by Dr. Pearson, as when the smaller proportion is employed.

The third formula quoted is a new one of the Dublin Pharmacopœia of 1850. By this formula the liquid, resulting from mixing aqueous solutions of tartar emetic and phosphate of soda, is precipitated by a solution of chloride of calcium, previously mixed with water of ammonia. The water of ammonia throws down teroxide of antimony from the tartar emetic; and the chloride of calcium, phosphate of lime from the phosphate of soda; and the mixed precipitate from these two sources, washed, dried, and reduced to fine powder, constitutes the new Dublin antimonial powder. As phosphate of lime is generally considered to be inert, it is questionable whether this powder will have any other therapeutic effect than that produced by the teroxide of antimony alone.

Properties, Composition, and Tests. Antimonial powder, as made by the old formula, is a tasteless, inodorous, gritty powder, of a dull-white colour. As often prepared it is insoluble in water; but usually a small portion, consisting of antimonite and superphosphate of lime, dissolves in boiling distilled water. Its composition varies exceedingly, a circumstance which forms a strong objection to it as a medicine. When entirely insoluble in boiling water, it probably contains nothing but antimonious acid and phosphate of lime; for, when its soluble constituents are absent, the teroxide is absent also. The best samples, as stated by the Edinburgh College, are formed of "a mixture chiefly of antimonious acid and phosphate of lime, with some sesquioxide [teroxide] of antimony, and a little antimonite of lime." To these ingredients may be added superphosphate of lime, which was found in small quantity by Dr. D. Maclagan, of Edinburgh. This writer obtained in his experiments about 50 per cent. of antimonious acid, 45 of phosphate of lime, nearly 4 of teroxide, and not quite 1 of antimonite and superphosphate of lime. The antimonial powder, sold by the representatives of Dr. James, is more active, and more uniform in its effects, than the imitation powder of the Pharmacopœias; its greater activity being explained by the presence of a greater proportion of teroxide, which Dr. Maclagan found to vary from four to ten per cent. In analyzing antimonial powder, the first step is to act on it with boiling distilled water. If any antimonite should be dissolved, the solution will form with sulphuretted hydrogen an orange-coloured precipitate of quadrisulphuret of antimony; if superphosphate be present, nitrate of silver will throw down phosphate of silver. What remains of the powder, unacted on by the distilled water, is next digested with muriatic acid, which will dissolve the phosphate of lime, and also teroxide of antimony if present, and leave a residue which is the antimonious acid. If teroxide be present in the muriatic solution, it will be precipitated by sulphuretted hydrogen, as an orange-coloured tersulphuret, and from the filtered solution, water of ammonia will throw down the phosphate of lime. In this way all the ingredients of antimonial powder may be detected and separated. It might be supposed that the muriatic solution would be more readily tested for the presence of teroxide by the action of water, which is known to cause a white precipitate of teroxide in this solution; but there appears to be some ambiguity in relation to the action of water. The Edinburgh College, in its formula of tests, states that the muriatic solution of the residue, left after the exhaustion by water, does not become turbid by dilution; but, according to Dr. Barker and Dr. Pereira, this effect sometimes takes place. These different results may be explained by the different qualities of the preparation. A small quantity of teroxide may be in the muriatic solution, and yet not be precipitated by water; while a larger quantity will be so precipitated. On the other hand a precipitate may be produced with water, without the fact proving the presence of teroxide; for, unless the antimonial powder be most carefully exhausted by the distilled water before being subjected to the acid, the muriatic solution may contain antimonite of lime, which, like the teroxide, gives it the property of becoming turbid with water.

Medical Properties and Uses. This preparation is stated to be alterative, diaphoretic, purgative, or emetic, according to the dose in which it is given. Until within a few years it was frequently used in febrile diseases, with a view to its diaphoretic effect. According to the late Dr. A. T. Thomson, it is advantageously given in acute rheumatism, conjoined with camphor, calomel, and opium, and with calomel and guaiac in several cutaneous affections. The estimation in which this preparation is held is very various. The late Dr. Duncan characterized it as one of the best antimonials we possess; yet he acknowledged that its effects are very unequal, either from idiosyncrasy in the patient, or variations in its composition. Dr. Thomson found it sometimes to answer his expectations, but as often to disappoint them. Mr. Brande admits its activity sometimes, and entire inertness at others; differences which he attributes to the presence or absence of *teroxide* of antimony. Upon the whole it appears that, whatever may be the occasional efficacy of this medicine, it is too variable in its composition, from circumstances in its preparation scarcely within the control of the pharmaceutical chemist, to make it a safe remedy. No therapeutical effect can be expected from it, which may not be more certainly and safely produced by tartar emetic; and it seems to be the sentiment of some of the best practitioners, that antimonial powder may very well be dispensed with as a remedy. Considerations of this kind caused it to be omitted from the U. S. Pharmacopœia, upon the revision of 1830.

The dose of antimonial powder, as a diaphoretic, is from three to eight grains every third or fourth hour, given in the form of pill. In larger doses it is purgative or emetic. It is impossible, however, to give precise directions as to the dose; as it sometimes proves violently emetic in moderate doses, and at other times produces no obvious effect, even in doses of one hundred grains. B.

AQUA.

Water.

AQUA DESTILLATA. *U. S., Lond., Ed., Dub. Distilled Water.*

"Take of Water *ten gallons.* First distil *two pints*, and throw them away; then distil *eight gallons.* Keep the Distilled Water in glass bottles." *U. S.*

"Take any convenient quantity of Spring Water; distil it from a proper vessel, rejecting the first twentieth part, and preserving the first half of the remainder." *Ed.*

"Take of Spring or River Water *any convenient quantity.* Having introduced it into a copper still, connected with a block-tin worm, or a Liebig's condenser, draw over about one-fortieth by distillation; this being rejected, continue the process until only one-fifth of the original volume of the Water remains in the still. Let the Distilled Water be preserved in well stopped bottles." *Dub.*

The *London* College has placed distilled water in the list of the Materia Medica.

The purest natural water is not sufficiently pure for some pharmaceutical purposes; and hence the necessity of the above processes for its distillation. It is best to reject the first portion which comes over, as this may contain carbonic acid and other volatile impurities; and the last portion of the water ought not to be distilled, lest it should pass over with an empyreumatic taste. The distillation is usually performed with the ordinary still and condenser, and such an apparatus is evidently contemplated in the United States formula. Mr. Brande states that distilled water often derives from the still a foreign flavour, which it is difficult to avoid. He, therefore, recommends that a still and condenser be kept exclusively for distilling water; or where this cannot be done, that steam be driven through the condensing pipe for half an hour, for the purpose of washing it out before it is used, the worm-tub having been previously emptied.

Properties, &c. Distilled Water, as usually obtained, has a vapid and disagreeable taste, and is not perfectly pure; water, to be rendered so, requiring to be distilled in silver vessels. The properties of pure water have already been given under the head of *Aqua*. Distilled water should undergo no change by sulphuretted hydrogen, or on the addition of tincture of soap, subacetate of lead, chloride of barium, oxalate of ammonia, nitrate of silver, or lime-water, and should evaporate without residue. It is uselessly employed in some formulæ, but is essential in others. As a general rule, when small quantities of active medicines are to be given in solution, and in the preparation of collyria, distilled water should be directed. The following list contains the chief substances which require distilled water as a solvent;—tartar emetic, corrosive sublimate, nitrate of silver, the chlorides of barium and calcium, acetate and subacetate of lead, the sulphates of iron and zinc, sulphate of quinia, and the sulphate, muriate, and acetate of morphia. Distilled water is used in preparing the officinal diluted acids, for absorbing gaseous ammonia, and for forming nearly all the officinal aqueous solutions. B.

AQUÆ MEDICATÆ. *U. S.*

Medicated Waters.

Under this head are included, in the United States Pharmacopœia, all those preparations consisting of water impregnated with some medicinal substance, which are not arranged in any other class. Among them are the "Waters" and "Distilled Waters" of the British Pharmacopœias, which therefore require some notice in the present place.

AQUÆ. *Lond.* WATERS. *Dub.* DISTILLED WATERS. *Ed.*

"Distilled waters may be prepared from fresh, and generally also from dried vegetables. In the latter case only half the weight of material should be used. They may also be prepared, for the most part, by agitating the volatile oils of the plants with water, and filtering the solution. But distilled waters obtained in this way have seldom so fine a flavour as those obtained from the plants themselves." *Ed.*

Many vegetables impart to water distilled from them their peculiar flavour, and more or less of their medical properties. The distilled waters chiefly used are those prepared from aromatic plants, the volatile oil of which rises with the aqueous vapour, and is condensed with it in the receiver. But as water is capable of holding but a small proportion of the oil in solution, these preparations are generally feeble, and are employed chiefly as pleasant vehicles or corrigents of other medicines.

In the preparation of the distilled waters, dried plants are sometimes used, because the fresh are not to be had at all seasons; but the latter, at least in the instance of herbs and flowers, should be preferred if attainable. Flowers which lose their odour by desiccation may be preserved by incorporating them intimately with one-third of their weight of common salt, and in this state afford distilled waters of delicate flavour.

It is necessary to observe certain practical rules in conducting the process of distillation. When the substance employed is dry, hard, and fibrous, it should be mechanically divided, and macerated in water for a short time previously to the operation. The quantity of materials should not bear too large a proportion to the capacity of the alembic, as the water might otherwise boil over into the receiver. The water should be brought quickly to the state of ebullition, and continued in that state till the end of the process. Care should be taken to leave sufficient water undistilled to cover the whole of the vegetable matter; lest

a portion of the latter, coming in contact with the sides of the vessel, might be decomposed by the heat, and yield empyreumatic products. Besides, when the operation is urged too vigorously or carried too far, a slimy matter is apt to form, which adheres to the sides of the alembic above the water, and is thus exposed to igneous decomposition. To obviate these disadvantages, the heat may be applied by means of an oil-bath regulated by a thermometer, or of a bath of solution of chloride of calcium, by which any temperature may be obtained between 212° and 270°, according to the strength of the solution; or, when the process is conducted upon a large scale, by means of steam introduced under pressure into a space around the still. A convenient mode of applying heat by steam, is by means of a coil of leaden tube placed in the bottom of the still, having one end connected with a boiler, and the other passing out beneath or at the side, and furnished with a stop-cock, by which the pressure may be increased, or the condensed water drawn off at will. If any volatile oil float upon the surface of the distilled water, it should be separated.

But, however carefully the process may be conducted, the distilled waters prepared from plants always have at first an unpleasant smoky odour. They may be freed from this by exposure for a short time to the air, before being enclosed in well stopped bottles, in which they should be preserved. When long kept, they are apt to form a viscid ropy matter, and to become sour. This result has been ascribed to other principles, which rise with the oil in distillation, and promote its decomposition. To prevent this decomposition, the *Edinburgh College* orders rectified spirit to be added to the water employed in the process of distillation. But this addition is inadequate to the intended object, and is in fact injurious, as the alcohol by long exposure to the air appears to undergo the acetous fermentation. The *London College*, which formerly directed a spirituous addition, has abandoned it. A better plan is to redistil the waters. When thus purified, it is said that they may be kept for several years unchanged.

Robiquet considers the mucosity which forms in distilled waters as the result of a vegetative process, to which the presence of air is essential. He has found that, so long as the water is covered with a layer of essential oil, it undergoes no change; but that the oil is gradually altered by exposure to the air, and, as soon as it disappears, the water begins to be decomposed. He states that camphor exercises the same preservative influence over the distilled waters by resisting the vegetation, and that those in which the odour of camphor is developed keep better on that account. Finally, he has observed that the more distilled water is charged with volatile oil, the more abundant is the mucosity, when it has begun to form. Robiquet unites with Henry and Guibourt, and with Virey, in recommending that all these waters, when intended to be kept for a considerable time, should be introduced, immediately after distillation, into bottles of a size proportionate to the probable consumption of the water when brought into use; and that the bottles should be quite filled, and then sealed or otherwise well stopped, so as entirely to exclude the air. Thus treated, they may be preserved without change for many years. (*Journ. de Pharm.*, xxi. 402.)

Another mode of preparing the distilled waters is to substitute the volatile oil previously separated from the plant, for the plant itself in the process. This mode was directed in former editions of the *London* and *Dublin* Pharmacopœias, in several instances, but has been omitted in the last editions. It is said to afford a more permanent product than the preceding; but does not always preserve the flavour of the plant.

In relation to most of the aromatics, the United States Pharmacopœia discards altogether the process by distillation, and directs that water should be impregnated with the volatile oil by trituration with carbonate of magnesia, and subsequently filtered. This is by far the most simple and easy process. The resulting solution is pure and permanent, and is perfectly transparent, the car-

bonate of magnesia being separated by the filtration. Carbonate of magnesia is preferable to the pure earth; as the latter sometimes gives a brownish colour to the liquid, and requires to be used in larger proportion. But both these substances are dissolved in minute quantities, and are apt to occasion a slight flocculent precipitate. They may also possibly prove injurious by decomposing certain substances given in very small doses, as sulphate of morphia, bichloride of mercury, and nitrate of silver. The object of the magnesia or its carbonate is simply to enable the oil to be brought to a state of minute division, and thus presented with a larger surface to the action of the solvent. According to Mr. Robert Warington, this object may be better accomplished by porcelain clay, finely powdered glass, or pumice stone, which are wholly insoluble (*Chem. Gaz.*, March, 1845, p. 113); and the London College now employs finely powdered silica for the purpose. (See *Silex Contritus.*) Chalk and sugar answer the same end; but the latter, by being dissolved with the oil, renders the preparation impure. The *Dublin College* prepares its waters by agitating an alcoholic solution of the oil with distilled water and filtering. They consequently contain alcohol, and are liable to the objection already mentioned against the medicated waters thus impregnated. They are besides feeble in the properties of their respective oils. In the preparation of the aromatic waters by these processes, it is very important that the water should be pure. The presence of a sulphate causes a decomposition of the oil, resulting in the production of sulphuretted hydrogen and a carbonate; and the aromatic properties are quite lost. (See *Am. Journ. of Pharm.*, xix. 303.) Hence the propriety of the officinal direction to employ distilled water. W.

AQUA ACIDI CARBONICI. *U.S. Carbonic Acid Water. Artificial Seltzer Water.*

"By means of a forcing pump, throw into a suitable receiver, nearly filled with Water, a quantity of carbonic acid equal to five times the bulk of the Water. Carbonic acid is obtained from Marble by means of dilute sulphuric acid." *U. S.*

This preparation, which is peculiar to the United States Pharmacopœia, consists of water highly charged with carbonic acid. Water is found to take up its volume of this acid under the pressure of the atmosphere; and Dr. Henry ascertained that precisely the same *volume* of the compressed gas is absorbed under a higher pressure. From this law, the bulk taken up is constant, the quantity being different in proportion as there is more or less driven into a given space. As the space occupied by a gas is inversely as the compressing force, it follows that the quantity of the acid forced into the water will be directly as the pressure. A double pressure will force a double quantity into a given space, and, therefore, cause a double quantity to be absorbed; a treble pressure will drive a treble quantity into the same space, and cause its absorption; and so on for higher pressures, the *bulk* of the *compressed* gas absorbed always remaining the same. From the principles above laid down, it follows that, to saturate water with five times its volume of carbonic acid, as directed in the formula, it must be subjected to a pressure of five atmospheres.

Carbonic acid water is familiarly called in this country "mineral water," and "soda water;" the latter name, originally applied to the preparation when it contained a small portion of carbonate of soda, being from habit continued since the alkali has been omitted. As it is largely consumed both as an agreeable beverage and as a medicine, it will be proper to give a sketch of the apparatus employed in its preparation. This consists of a strong egg-shaped copper vessel, about eighteen inches long, called a generator, fixed upright in a wooden frame, and surmounted by another upright vessel of similar shape, about nine inches long, communicating with the generator by a short neck, and intended to contain the sulphuric acid. Connected with the generator by a copper tube, and placed

by its side, is a strong cylindrical vessel for washing the gas, about fifteen inches long and three and a half in diameter, two-thirds filled with water, and to near the bottom of which the connecting tube passes. Severally communicating with the washing vessel are a mercurial gauge to indicate the pressure, and a strong vessel, called the reservoir or fountain, of about the capacity of eighteen gallons, three-fourths filled with water, the connexion of the latter being by a lead or gutta percha tube, commanded by a stop-cock. The charge of whiting or marble dust, say eight pounds, and the requisite water are added through an opening in the generator, in front of the sulphuric acid vessel, and closed by a screw stopper. The communication between the acid vessel and generator is commanded by a vertical square rod, reaching within the vessel to about two-thirds of its height, and terminating at its lower end in a screw. This rod, when unscrewed, opens a communication between the acid vessel and the generator. The requisite sulphuric acid is added to the acid vessel through an opening at its top, capable of being closed by a screw stopper. Through the axis of this stopper, and revolving within it, but without having any vertical motion on it, passes the key, the lower end of which has a square hole to fit on the square rod. When the acid vessel is to be closed, the screw stopper, with its key, is placed over the opening, in which situation the lower end of the key reaches down a sufficient distance to embrace loosely the square rod. The stopper is now screwed in, and the key, without revolving with the stopper, descends so as duly to embrace the square rod. By turning the handle of the key in the proper direction, the rod is partially unscrewed, the passage to the generator opened, and the acid gradually flows in. From time to time, when the acid is allowed to enter the generator, its contents are briskly mixed by means of an agitator, attached to a horizontal axis, passing air-tight through the short diameter of the generator, and turned by a crank. The stop-cock between the washing vessel and fountain is now partially opened, and the impregnation of the water with the gas begins. As it proceeds, the sulphuric acid is gradually allowed to enter the generator until it is expended, and the stop-cock is from time to time turned, until it is entirely opened. Finally, after the water is fully charged with gas, and the whiting wholly decomposed, the fountain is detached, and the generator freed from the pulpy sulphate of lime by the assistance of water and the agitator, and its contents allowed to escape through an opening in its most depending part. In the apparatus of the size above described, a single fountain only is charged by one operation, and the carbonic acid water formed contains between nine and ten times its volume of the gas. In this improved mode of making carbonic acid water, it is perceived that the requisite pressure is obtained by generating the carbonic acid in a confined space, instead of by a forcing pump.

Carbonic acid water is dispensed in many of the apothecary shops in the United States. The fountain is usually placed in the cellar, and the tube proceeding from the fountain is made to pass through the floor and counter of the shop, and to terminate in a stop-cock, by means of which the carbonic acid water may be drawn off at pleasure. In order to have the liquid cool in summer, the tube from the cellar generally terminates in a strong metallic vessel of convenient shape, placed under the counter and surrounded with ice, and from this vessel a separate tube penetrating the counter proceeds.

Properties. Carbonic acid water is a sparkling liquid, possessing an agreeable, pungent, acidulous taste. It reddens litmus deeply from its state of concentration, and is precipitated by lime-water. Being impregnated with a large quantity of the acid gas under the influence of pressure, it effervesces strongly when freed from restraint. Hence, to preserve its briskness, it should be kept in strong well-corked bottles, placed inverted in a cool place. Several natural waters are of a similar nature; such as those of Seltzer, Spa, and Pyrmont; but the artificial water has the advantage of a stronger impregnation with the acid

gas. Carbonic acid water, when pure, is not discoloured by sulphuretted hydrogen or solution of ammonia, nor precipitated by sulphate of soda or ferrocyanuret of potassium. It should be made with every precaution to avoid metallic impurity. Hence the necessity of having the reservoir or fountain well tinned on the inner surface. Even with this precaution, a slight metallic impregnation is not always avoided, especially in the winter season, when the water is less consumed as a drink, and, therefore, allowed to remain longer in the reservoir. Glass fountains are sometimes used with advantage at this season; and a patent has been taken out for a stoneware fountain, enclosed in tinned copper, which has been found to answer a good purpose. When leaden tubes are employed to convey the water, it is liable to be contaminated with this metal, which renders it deleterious. A case of colica pictonum was treated by one of the authors, arising from the daily use of the first draught of carbonic acid water from a fountain furnished with tubes of lead. Tin tubes are sometimes employed, enclosed in lead ones to give them strength.

Carbonic acid, formerly called *fixed air*, is a colourless gas, of a slightly pungent odour and acid taste. It reddens litmus feebly, and combines with salifiable bases, forming salts called carbonates, from which it is expelled by all the strong acids. It extinguishes flame, and is quickly fatal to animals when respired. All kinds of fermented liquors which are brisk or sparkling, such as champagne, cider, porter, &c., owe these properties to its presence. Its sp. gr. is 1·52. In 1823 it was liquefied by Faraday by a pressure of 36 atmospheres, and in 1836 solidified by Thilorier, by taking advantage of the cold generated by the sudden gasefaction of the liquid acid, when freed from pressure. It is composed of one eq. of carbon 6, and two of oxygen 16=22.

Medical Properties and Uses. Carbonic acid water is diaphoretic, diuretic, and anti-emetic. It forms a grateful drink to febrile patients, allaying thirst, lessening nausea and gastric distress, and promoting the secretion of urine. The quantity taken need only be regulated by the reasonable wishes of the patient. It also forms a very convenient vehicle for the administration of magnesia, the carbonated alkalies, sulphate of magnesia, and the saline cathartics generally; rendering these medicines less unpleasant to the palate, and, in irritable states of the stomach, increasing the chances of their being retained. When used for this purpose, six or eight fluidounces will be sufficient.

Carbonic acid gas has been used by Professor Mojon, of Geneva, as an injection in dysmenorrhœa with the most soothing effects. It is applied by means of a flexible tube, inserted into the vagina, and proceeding from a bottle containing pieces of chalk and dilute sulphuric acid. The application is continued for five minutes, and repeated several times a day. (*Am. Journ. of the Med. Sci.*, xxii. 469, from the *Bull. Gén. de Thérap.*) B.

AQUA AMYGDALÆ AMARÆ. *U. S. Bitter Almond Water.*

"Take of Oil of Bitter Almonds *sixteen minims;* Carbonate of Magnesia *a drachm;* Water *two pints.* Proceed in the manner directed for Cinnamon Water." *U. S.*

This preparation has the effects of hydrocyanic acid on the system, and may be used as a vehicle of other medicines in nervous coughs, and various spasmodic affections. It is, however, liable to spontaneous change, and is consequently more or less uncertain. A drop of sulphuric acid added to a pint of it will contribute to its preservation; as will also complete exclusion from the light and air. But the better plan is to prepare it in small quantities, as wanted for use. The dose of it, to begin with, when of full strength, should not exceed half a fluidounce. Under the same name, a preparation has been considerably used on the continent of Europe, prepared by distilling bitter almonds with water. This when fresh is much stronger than the preparation of the U. S. Pharmacopœia,

containing, according to an analysis of Geiger, in 1000 parts, 1·2 parts of anhydrous hydrocyanic acid. It has been prescribed with fatal effects (*Pharm. Journ. and Trans.*, vi. 439); and the greatest caution, therefore, should be observed by the apothecary not to put up the distilled water instead of the officinal. W.

AQUA ANETHI. *Lond., Ed. Dill Water.*

"Take of Dill [fruit], bruised, *a pound and a half;* Water *two gallons* [Imperial measure]. Distil a gallon." Or, "Take of Oil of Dill *two fluidrachms;* Pulverized Silex *two drachms;* Distilled Water *a gallon* [Imp. meas.]. Rub the oil diligently, first with the Silex, afterwards with the Water, and filter the solution." *Lond.*

The *Edinburgh College* takes the same quantity of dill and of water, with *three fluidounces* of rectified spirit, mixes, and distils a gallon.

This is seldom if ever used in the United States. W.

AQUA ANISI. *Dub. Anise Water.*

"Take of Essence of Anise *one fluidounce;* Distilled Water *half a gallon* [Imperial measure]. Mix with agitation, and filter through paper." *Dub.*

This preparation is seldom used in the United States. W.

AQUA CAMPHORÆ. *U.S.* MISTURA CAMPHORÆ. *Lond., Ed., Dub. Camphor Water.*

"Take of Camphor *two drachms;* Alcohol *forty minims;* Carbonate of Magnesia *four drachms;* Distilled Water *two pints.* Rub the Camphor first with the Alcohol, afterwards with the Carbonate of Magnesia, and lastly with the Water gradually added; then filter through paper." *U. S.*

The *London College* takes *half a drachm* of camphor, *ten minims* of rectified spirit, and *a pint* [Imperial measure] of distilled water; rubs the camphor first with the spirit, and then with the water gradually added; and strains through linen. The *Edinburgh College* directs *a scruple* of camphor and *half an ounce* of sugar, well rubbed together, to be beat, with *half an ounce* of blanched sweet almonds, into a smooth pulp; *a pint* [Imp. meas.] of water to be gradually added, and the mixture to be strained. The *Dublin College* takes *a fluidounce* of tincture of camphor, and *three pints* [Imp. meas.] of water; shakes the tincture and water together in a bottle, and, after the mixture has stood twenty-four hours, filters through paper.

In all these processes the object is to effect a solution of the camphor. Water is capable of dissolving but a small proportion of this principle; but the quantity varies with the method employed. The London and Dublin preparations are very feeble. Made according to the Edinburgh process, one pint of the water contains less than twenty grains of camphor; while our own officinal preparation contains about fifty grains to the pint, or more than three grains to the fluidounce. (*Journ. of the Phil. Col. of Pharm.*, iv. 13.) The difference is attributable, at least in part, to the minute division effected in the camphor by trituration with the carbonate of magnesia, which is afterwards separated by filtration. The use of the alcohol is simply to break down the cohesion of the camphor, and enable it to be more easily pulverized. The process of the U. S. Pharmacopœia is much preferable to the others, as it affords a permanent solution, of sufficient strength to be employed with a view to the influence of the camphor on the system; while the British preparations have little more than the flavour of the narcotic, and are fit only for vehicles of other medicines. The camphor is separated by a solution of pure potassa, and, according to Dr. Paris, by sulphate of magnesia and several other salts. Sir J. Murray proposes a solution of camphor and bicarbonate of magnesia, which contains three grains of the former and six grains of the latter in each fluidounce. (See *Am. Journ. of Pharm.*, xx. 195.)

Camphor water is chiefly employed in low fevers and typhoid diseases, attended with restlessness, slight delirium, or other symptoms of nervous derangement or debility. It is used also to allay uterine after-pains. It has this advantage over camphor in substance, that the latter is with difficulty dissolved by the liquors of the stomach; but it is not applicable to cases where very large doses of the medicine are required. It is usually given in the dose of one or two tablespoonfuls repeated every hour or two hours. W.

AQUA CARUI. *Lond., Dub. Caraway Water.*

The *London College* prepares this in the same manner as *Dill Water.* (See *Aqua Anethi.*) The *Dublin College* takes *a fluidounce* of the essence of caraway, and *half a gallon* [Imperial measure] of distilled water, mixes with agitation, and filters through paper.

Caraway water has the flavour and pungency of the seeds, but is not used in this country. W.

AQUA CASSIÆ. *Ed. Water of Cassia.*

"Take of Cassia-bark, bruised, *eighteen ounces;* Water, two *gallons* [Imperial measure]; Rectified Spirit *three fluidounces.* Mix them together, and distil off one gallon." *Ed.*

The distinction between cassia and cinnamon is not recognised in our Pharmacopœia; so that this preparation would rank as a variety of cinnamon water. (See *Aqua Cinnamomi.*) W.

AQUA CINNAMOMI. *U. S., Lond., Ed., Dub. Cinnamon Water.*

"Take of Oil of Cinnamon *half a fluidrachm;* Carbonate of Magnesia *a drachm;* Distilled Water *two pints.* Rub the Oil of Cinnamon first with the Carbonate of Magnesia, then with the Water gradually added, and filter through paper." *U. S.*

The *London College* prepares this in the same manner as Dill Water; the *Edinburgh*, as the Water of Cassia. The *Dublin College* takes *a fluidounce* of essence of cinnamon, and *half a gallon* [Imperial measure] of distilled water, mixes with agitation, and filters through paper.

Of these processes, we prefer that of the U. S. Pharmacopœia or the second London process, as easier than the others, or affording a better product. Cinnamon water is much used as a vehicle for other less agreeable medicines; but should be given cautiously in inflammatory affections. For ordinary purposes it is sufficiently strong when diluted with an equal measure of water.

Off. Prep. Mistura Cretæ; Mistura Guaiaci; Mistura Spiritûs Vini Gallici. W.

AQUA FŒNICULI. *U. S., Ed., Dub. Fennel Water.*

The U. S. Pharmacopœia directs this to be prepared from oil of fennel, in the same manner as cinnamon water. (See *Aqua Cinnamomi.*)

The *Edinburgh College* prepares it in the same manner as dill water (see *Aqua Anethi*). The *Dublin College* takes *a fluidounce* of the essence of fennel, and *half a gallon* [Imperial measure] of distilled water, mixes with agitation, and filters through paper.

Fennel water is an agreeable vehicle for other medicines, and useful when a mild aromatic is indicated. W.

AQUA LAURO-CERASI. *Ed., Dub. Cherry-laurel Water.*

"Take of Fresh Leaves of Cherry-laurel, *a pound;* Water *two pints and a half* [Imperial measure]; Compound Spirit of Lavender *an ounce.* Chop down the Leaves, mix them with the Water, distil off one pint [Imp. meas.], agitate the distilled liquid well, filter it if any milkiness remain after a few seconds of rest, and then add the Lavender Spirit." *Ed.*

"Take of Fresh Leaves of the Common Laurel, *one pound;* Water *two pints and a half* [Imperial Measure]. Upon the Leaves, chopped, and crushed in a mortar, macerate the Water for twenty-four hours, and then draw over a pint of liquid by distillation, using a Liebig's condenser, and chloride of zinc bath. Filter the product through paper, and preserve it in a well-stopped bottle." *Dub.*

The leaves yield a larger product of hydrocyanic acid when cut and bruised than when distilled whole. According to M. Garot, the proportion of the acid in cherry-laurel water depends upon the time of year at which the distillation is performed; the leaves yielding not more than half as much in April, as in the middle of July. (*Annuaire de Thérap.*, 1843, p. 45.) The use of compound spirit of lavender, in the Edinburgh formula, instead of alcohol, is in order to impart colour to the preparation, and thus prevent it from being mistaken for common water. The proportion of hydrocyanic acid in the water diminishes with time. It has been ascertained by M. Deschamps, that if a drop of sulphuric acid be added to a pint of the preparation, it will keep unchanged for at least a year. It is best preserved by the entire exclusion of air and light. M. Lepage found that, preserved in full and perfectly air-tight bottles, both this and bitter almond water remained unchanged at the end of a year; while freely exposed to the air, they lost all their hydrocyanic acid and essential oil in two or three months. (*Journ. de Pharm. et de Chim.*, xvi. 346.) Cherry-laurel water is employed in Europe as a sedative narcotic, identical in its properties with a dilute solution of hydrocyanic acid; but it is of very uncertain strength. The dose is from thirty minims to a fluidrachm. W.

AQUA MENTHÆ PIPERITÆ. *U. S., Lond., Ed., Dub. Peppermint Water.*

This is prepared, according to the U. S. Pharmacopœia, from the oil of peppermint, in the manner directed for cinnamon water. (See *Aqua Cinnamomi.*)

"Take of Peppermint, dried, *two pounds;* Water *two gallons* [Imperial measure]. Distil *a gallon.* When the fresh herb is used the quantity should be doubled. This Water may be more quickly prepared from the Oil of Peppermint in the same manner as Dill Water." *Lond.*

The *Edinburgh College* mixes *four pounds* of fresh or *two* of dry peppermint, *two gallons* [Imp. meas.] of water, and *three fluidounces* of rectified spirit, and distils a gallon. The *Dublin College* mixes, with agitation, *a fluidounce* of essence of peppermint with *half a gallon* [Imp. meas.] of distilled water, and filters through paper. W.

AQUA MENTHÆ VIRIDIS. *U. S., Lond., Ed., Dub. Spearmint Water.*

This is prepared, according to the U. S. Pharmacopœia, from the oil of spearmint, in the manner directed for cinnamon water. (See *Aqua Cinnamomi.*)

By the British Colleges it is prepared in the manner directed by them for peppermint water.

The two mint waters are among the most grateful and most employed of this class of preparations. Together with cinnamon water, they are used in this country, almost to the exclusion of all others, as the vehicle of medicines given in the form of mixture. They serve not only to conceal or qualify the taste of other medicines, but also to counteract their nauseating properties. Peppermint water is generally thought to have a more agreeable flavour than that of spearmint, but some prefer the latter. Their effects are the same. W.

AQUA PIMENTÆ. *Lond., Ed., Dub. Pimento Water.*

"Take of Pimento, bruised, *a pound;* Water *two gallons* [Imperial measure]. Distil a gallon. This Water may be more quickly prepared from Oil of Pimento in the same manner as Dill Water." *Lond.*

The *Edinburgh College* mixes *a pound* of bruised pimento, *two gallons* [Imp. meas.] of water, and *three fluidounces* of rectified spirit, and distils a gallon. The *Dublin College* agitates *a fluidounce* of essence of pimento with *half a gallon* [Imp. meas.] of distilled water, and filters through paper.

Pimento water is brownish when first distilled, and upon standing deposits a brown resinous sediment. It is used as a carminative in the dose of one or two fluidounces. W.

AQUA PULEGII. *Lond., Ed.* AQUA MENTHÆ PULEGII. *Dub. Pennyroyal Water.*

This is prepared from European pennyroyal or its oil, precisely in the manner directed by the British Colleges for peppermint water. It is not used in this country, as we have not the plant. A water prepared from *Hedeoma pulegioides*, or American pennyroyal, might be substituted.

Pennyroyal water is employed for the same purposes as those of peppermint and spearmint. W.

AQUA ROSÆ. *U. S., Lond., Ed., Dub. Rose Water.*

"Take of Fresh Hundred-leaved Roses *eight pounds;* Water *two gallons.* Mix them and distil a gallon." *U. S.*

The *London College* takes *ten pounds* of roses and *two gallons* [Imperial measure] of water, and distils a gallon. The *Edinburgh College* mixes *ten pounds* of roses, *two gallons* [Imp. meas.] of water, and *three fluidounces* of rectified spirit, and distils off *a gallon;* adding the following notice. "The petals should be preferred when fresh; but it also answers well to use those which have been preserved by beating them with twice their weight of muriate of soda." The *Dublin College* agitates *twenty minims* of oil of roses with *half a gallon* [Imp. meas.] of distilled water, and filters through paper.

It should be observed that, in the nomenclature of the U. S. Pharmacopœia, the term "Roses" implies only the petals of the flower. These are directed in the recent state; but it is said that, when preserved by being incorporated with one-third of their weight of common salt, they retain their odour, and afford a water equally fragrant with that prepared from the fresh flower. It is not uncommon to employ the whole flower including the calyx, but the product is less fragrant than when the petals only are used, as officinally directed. Rose water is sometimes made by distilling together water and the oil of roses.

When properly prepared, it has the delightful perfume of the rose in great perfection. It is most successfully made on a large scale. Like the other distilled waters it is liable to spoil when kept; and the alcohol which is sometimes added to preserve it is incompatible with some of the purposes to which the water is applied, and is even said to render it sour through acetous fermentation. It is best, therefore, to avoid this addition, and to substitute a second distillation. This distilled water is chiefly employed, on account of its agreeable odour, in collyria and other lotions. It is wholly destitute of irritating properties, unless when it contains alcohol.

Off. Prep. Confectio Rosæ; Mistura Ferri Composita; Unguentum Aquæ Rosæ. W.

AQUA SAMBUCI. *Lond., Ed. Elder Water.*

"Take of Elder Flowers *ten pounds;* Water *two gallons* [Imperial measure]. Distil a gallon." *Lond.*

The *Edinburgh College* mixes *ten pounds* of the fresh flowers, two gallons [Imp. meas.] of water, and *three fluidounces* of rectified spirit, and distils a gallon.

Elder flowers yield very little oil upon distillation; and if the water be needed, it may be best prepared from the flowers. In this country it is not used. W.

CHLORINII LIQUOR. *Dub.* Chlorinei Aqua. *Ed.* *Solution of Chlorine. Chlorine Water.*

"Take of Peroxide of Manganese, in fine powder, *half an ounce* [avoirdupois]; Muriatic Acid of Commerce *three fluidounces* [Imp. meas.]; Distilled Water *twenty-four ounces* [avoird.]. Introduce the Peroxide of Manganese into a gas bottle, and having poured upon it the Muriatic Acid diluted with two ounces of [the] Water, apply a gentle heat, and, by suitable tubes, cause the gas, as it is developed, to bubble through two additional ounces of the Water placed in an intermediate small vial, and then to pass to the bottom of an [Imperial] three-pint bottle, containing the remainder of the Water, and whose mouth is loosely plugged with tow. When the air has been entirely displaced by the chlorine, let the bottle be disconnected from the apparatus in which the gas is generated, corked loosely, and shaken until the chlorine is absorbed. It should be now transferred to an [Imperial] pint bottle with a well-ground glass stopper, and preserved in a cool and dark place." *Dub.*

"Take of Muriate of Soda [chloride of sodium] *sixty grains;* Sulphuric Acid (commercial) *two fluidrachms* [Imp. meas.]; Red Oxide of Lead *three hundred and fifty grains;* Water *eight fluidounces* [Imp. meas.]. Triturate the Muriate of Soda and Oxide together; put them into the Water contained in a bottle with a glass stopper; add the Acid; agitate occasionally till the Red Oxide becomes almost all white. Allow the insoluble matter to subside before using the liquid." *Ed.*

In order to understand the Dublin process for making chlorine water, it is necessary to recollect that twenty-four avoirdupois ounces of water are equal to twenty-four Imperial fluidounces, and that the Imperial pint contains twenty fluidounces. The three-pint bottle used, therefore, has the capacity of sixty fluidounces. Four fluidounces of the water are appropriated in diluting the acid and in absorbing impurities in the intermediate vial. The remaining twenty fluidounces, or an Imperial pint, is placed in the three-pint bottle, which it only one-third fills. The chlorine gas is extricated from the muriatic acid by the deutoxide of manganese separating the hydrogen, and is passed into the three-pint bottle, loosely stopped, until the vacant part, having the capacity of two pints, is filled with it to the exclusion of atmospheric air. The bottle, being then corked, is shaken, so as to cause the absorption of the gas by the water. The product is an Imperial pint of chlorine water, which is transferred to a bottle just sufficient in capacity to contain it.

By the Edinburgh process the solution is formed in the liquid way. The red oxide of lead oxidizes the sodium, converting it into soda, and is itself reduced to the state of protoxide. The chlorine set free is dissolved by the water, and the sulphuric acid forms with the soda, sulphate of soda which remains in solution, and with the protoxide of lead, sulphate of protoxide of lead which is precipitated. The action is completed in the course of a few hours, and the sulphate of lead having subsided, the supernatant liquid forms an aqueous solution of chlorine, containing a little sulphate of soda, which does not interfere with its medicinal properties.

Properties. The Dublin chlorine water has a pale yellowish-green colour, an astringent taste, and the peculiar odour of the gas. Like gaseous chlorine it destroys vegetable colours. When cooled to about the freezing point, it forms deep-yellow crystalline plates, consisting of hydrate of chlorine. As prepared by the Dublin College, it is intended to contain twice its volume of the gas. It is decomposed by light, with the production of muriatic acid, and the evolution of oxygen, and hence must be kept in a dark place. According to MM. Riegel and Waltz, chlorine water, containing two and a half volumes of the gas at 54°, keeps best.

Chlorine is an elementary gaseous fluid, of a greenish-yellow colour, and characteristic smell and taste. It is a supporter of combustion. Its specific gravity is 2·47, and equivalent number 35·42. When the attempt is made to breathe it, even much diluted, it excites cough and a sense of suffocation, and causes a discharge from the nostrils like coryza. Breathed in considerable quantities, it produces spitting of blood, violent pains, and sometimes death.

Medical Properties and Uses. Chlorine water is stimulant and antiseptic. It has been used in typhus, and chronic affections of the liver; but the diseases in which it has been most extolled are scarlatina and malignant sorethroat. Externally it may be used, duly diluted, as a gargle in smallpox, scarlatina, and putrid sorethroat, as a wash for ill-conditioned ulcers and cancerous sores, and as a local bath in diseases of the liver. It has been used with advantage as an application to buboes and large abscesses, promoting the absorption of the matter. As it depends upon chlorine for its activity, its medical properties coincide generally with those of chlorinated lime, chlorinated soda, and nitromuriatic acid, under which heads they are more particularly given. The dose of chlorine water is from one to four fluidrachms, properly diluted.

Gaseous chlorine has been recommended in minute doses, by Gannal, in chronic bronchitis and pulmonary consumption, exhibited by inhalation four or six times a day. Its first effect is to produce some dryness of the fauces, with increased expectoration for a time, followed ultimately with diminution of the sputa and amendment. Dr. Christison states that he has repeatedly observed these results in chronic catarrh; and in consumption, both he and Dr. Elliotson have witnessed the temporary melioration of the symptoms from chlorine inhalations, such as they never obtained by any other means. The liquid in the inhaler may be formed either of water containing from ten to thirty drops of chlorine water, or of chlorinated lime dissolved in forty parts of water, to which a drop or two of sulphuric acid must be added, each time the inhalation is practised. The inhaler should be placed in water, heated to about 100°. B.

ARGENTUM.

Preparations of Silver.

ARGENTI CYANURETUM. *U. S. Cyanuret of Silver. Cyanide of Silver.*

"Take of Nitrate of Silver, Ferrocyanuret of Potassium, each, *two ounces;* Sulphuric Acid *an ounce and a half;* Distilled Water *a sufficient quantity.* Dissolve the Nitrate of Silver in a pint of Distilled Water, and pour the solution into a tubulated glass receiver. Dissolve the Ferrocyanuret of Potassium in ten fluidounces of Distilled Water, and pour the solution into a tubulated retort, previously adapted to the receiver. Having mixed the Sulphuric Acid with four fluidounces of Distilled Water, add the mixture to the solution in the retort, and distil by means of a sand-bath, with a moderate heat, until six fluidounces pass over, or until the liquid that passes produces no longer a precipitate in the receiver. Finally, wash the precipitate with distilled water, and dry it." *U. S.*

This preparation was originally introduced into the U.S. Pharmacopœia for the purpose of being used in the extemporaneous preparation of diluted hydrocyanic acid. (See *page* 805.) By the formula adopted in the Pharmacopœia of 1840, the officinal hydrocyanic acid was added to a solution of nitrate of silver. The expenditure in this way of the officinal acid, which is very weak, and at the same time nicely adjusted to a given strength, was injudiciously directed; and, accordingly, that formula has been abandoned, and a new process adopted

in the Pharmacopœia of 1850, in which all the silver contained in a given weight of nitrate of silver, placed in a receiver in solution is converted into cyanuret, by hydrocyanic acid, extricated from ferrocyanuret of potassium by the action of sulphuric acid. By a double decomposition between the oxide of silver of the nitrate and the hydrocyanic acid, water and cyanuret of silver are formed in the receiver, the latter of which precipitates. The materials in the retort are sufficient to produce a little more hydrocyanic acid than is necessary to convert the whole of the silver in the receiver into cyanuret; so that the complete decomposition of the nitrate of silver is insured.

According to Messrs. Glassford and Napier, the best way of obtaining cyanuret of silver is to add cyanuret of potassium to a solution of nitrate of silver, so long as a precipitate is formed.

Properties. Cyanuret of silver is a tasteless white powder, insoluble in water and cold nitric acid, but readily soluble, with decomposition, in that acid when boiling hot. It is decomposed by muriatic acid, exhaling the odour of hydrocyanic acid. It is not soluble in potassa or soda, but readily so in ammonia. Its best solvent is cyanuret of potassium. When heated it is decomposed, cyanogen being evolved, and metallic silver left. It consists of one eq. of cyanogen 26, and one of silver 108=134. It has no medical uses.

Off. Prep. Acidum Hydrocyanicum Dilutum. B.

ARGENTI NITRAS. *U. S. Nitrate of Silver. Nitrate of Silver in Crystals.*

"Take of Silver, in small pieces, *an ounce;* Nitric Acid [sp. gr. 1·42] *seven fluidrachms;* Distilled Water *two fluidounces.* Mix the acid with the Water, and dissolve the Silver in the mixture, on a sand-bath, with a gentle heat. Pour off the clear solution into a porcelain capsule, and, having evaporated it to one-half, allow it to cool that crystals may form. Pour off the supernatant liquid, and, after due evaporation, put it aside for the formation of fresh crystals. Again pour off the liquid, and evaporate for a third crop of crystals. Lastly, place the crystals in a glass funnel, in order that they may drain, and, when they are dry, put them into a bottle, which is to be well stopped, and protected from the light. The silver remaining in the mother water of the last crystallization may be obtained by introducing into it a plate of copper, which will precipitate the whole of the silver in the form of a gray powder, which, when washed with water, will be perfectly pure." *U. S.*

During the solution of silver in nitric acid, part of the acid is decomposed into nitric oxide which is given off and becomes red fumes by contact with the atmosphere, and oxygen which oxidizes the silver. The oxide formed then combines with the remainder of the acid, and generates the nitrate of silver in solution, which, by due evaporation, furnishes crystals of the salt. The silver should be pure, and the acid diluted for the purpose of promoting its action. If the silver contain copper, the solution will have a greenish tint, not disappearing on the application of heat; and if a minute portion of gold be present, it will be left undissolved as a black powder. The acid also should be pure. The commercial nitric acid, as it frequently contains both muriatic and sulphuric acids, should never be used in this process. The muriatic acid gives rise to an insoluble chloride, and the sulphuric, to the sparingly soluble sulphate of silver.

Properties. Nitrate of silver is in colourless transparent crystals, having the form of rhomboidal plates, sometimes of considerable size. Its taste is intensely metallic and bitter. It is soluble in its own weight of cold water, and in four parts of boiling alcohol. When perfectly pure, it is wholly soluble in distilled water. The solution stains the skin of an indelible black colour, and is itself discoloured by the most minute portion of organic matter, of which it forms a delicate test. The affinity of this salt for animal matter is evinced by its form-

ing definite compounds with albumen and fibrin. The solution also stains linen and muslin in a similar manner; and hence its use in making the so-called indelible ink. To remove these stains, Mr. W. B. Herapath advises to let fall on the moistened spots a few drops of tincture of iodine, which converts the silver into iodide of silver. The iodide is then dissolved by a solution of hyposulphite of soda, made of the strength of half a drachm to a fluidounce of water, or by a moderately dilute solution of caustic potassa, and the spots are washed out with warm water. Stains may be removed from the skin by the same reagents. When exposed to heat nitrate of silver fuses at 426°, and upon concreting forms the fused nitrate, which is officinal under the name of *Argenti Nitras Fusus*. At about 600° it undergoes decomposition with evolution of oxygen and nitrous acid, and the metal is revived. This statement explains the necessity of guarding against the application of too high a heat during the fusion of the salt. Nitrate of silver is incompatible with almost all spring and river water, on account of the common salt usually contained in it; with soluble chlorides; with sulphuric, hydrosulphuric, muriatic, and tartaric acids, and their salts; with the alkalies and their carbonates; with lime-water; and with astringent vegetable infusions. It is an anhydrous salt, and consists of one eq. of nitric acid 54, and one of protoxide of silver 116=170.

Impurities and Tests. A solution of chloride of sodium, when added in excess to one of nitrate of silver, should throw down the whole of the silver as a white curdy precipitate, and nothing besides. This precipitate should be entirely soluble in ammonia. If not entirely soluble, the insoluble part is probably chloride of lead. If the supernatant liquid, after the removal of the above-mentioned precipitate, be discoloured or precipitated by sulphuretted hydrogen, the fact shows the presence of metallic matter, which is probably copper or some remains of lead, or both. After all, the best test of nitrate of silver is the characteristic appearance of the crystals of the pure salt. For further tests of nitrate of silver, see *Argenti Nitras Fusus*.

Medical Properties. Nitrate of silver, as an internal remedy, is deemed tonic and antispasmodic. The principal diseases in which it has been employed are epilepsy, chorea, angina pectoris, and other spasmodic affections. In epilepsy it forms our most reliable remedy; but the kind of cases to which it is particularly applicable and its modus operandi are not understood. It is said to produce most good in this disease when it acts upon the bowels. Dr. James Johnson and other practitioners have found it useful, as a palliative and sedative, in chronic disease of the stomach attended with pain and vomiting. Dr. J. F. Peebles, of Petersburgh, Va., bears testimony to its efficacy in jaundice connected with gastric irritation, given preferably on an empty stomach. (*Am. Journ. of the Med. Sciences*, July 1849.) Dr. Boudin, of Marseilles, has employed it in typhoid fever as a remedy for the inflammation and ulceration of the ileum, which constitute the most constant lesion in that disease. When the gastric symptoms predominate, he gives the nitrate in pill, in doses of from the fourth to the half of a grain. When diarrhœa is the principal symptom, he administers, night and morning by injection, a solution of the salt containing three or four grains to six fluidounces of water. The injections appear to be useful by promoting the cicatrization of the intestinal ulcers, and were found to extend their operation as high up as the small intestines. M. Delioux, of Rochefort, has proposed albuminous injections of nitrate of silver in diarrhœa, formed of half a pint of water, containing the white of one egg, from two to four grains of the nitrate, and an equal weight of common salt. Nitrate of silver is soluble in an excess of an albuminous solution, and when thus prepared is more readily absorbed than when dissolved in water. The common salt promotes its solution without decomposing it. (*Journ. de Pharm.* xx. 149.) In chronic

diarrhœa, especially in that kind attendant on phthisis, Dr. Macgreggor, of Dublin, has found the nitrate of silver, conjoined with opium, a valuable remedy. Whatever may be the remedial value of this salt internally administered, its occasional effect of producing a slate-coloured discoloration of the skin, which is seldom removed, is a great objection to its use. This effect proves the absorption of the medicine, and is alleged to show itself first on the tongue and fauces. According to Dr. Branson, an indication of the approach of discoloration is furnished by the occurrence of a dark blue line on the edges of the gums, very similar to that produced by lead, but somewhat darker. The discoloration of the skin is said to be removed by a steady course of cream of tartar.

Externally, nitrate of silver is occasionally employed in solution as a stimulant and escharotic; but the *fused nitrate*, which is not so pure as the officinal *nitrate* (pure salt in crystals), is generally used for making solutions. In all cases requiring nicety, the officinal nitrate (crystals) should be directed to be dissolved, and distilled water should be selected as the solvent. A solution made in the proportion of half a grain of the crystals to a fluidounce of distilled water, forms a good mouth wash for healing ulcers produced by mercury. In the inflammation of the mouth from mercurial salivation, M. Bouchacourt found a concentrated solution of the salt, applied to the gums, base of the tongue, &c. with a camel's hair brush, very useful. A solution containing two grains of the crystals to a fluidounce of distilled water is an excellent application in ophthalmia with ulcers of the cornea, in fetid discharges from the ear, aphthous affections of the mouth, and spongy gums.

The dose of nitrate of silver (crystals) is the fourth of a grain, gradually increased to four or five grains, three times a day. For internal exhibition, the physician should always prescribe the crystals, which are meant by the name Argenti Nitras, in the revised nomenclature of the U. S. Pharmacopœia of 1850, and never direct the fused nitrate (Argenti Nitras Fusus), which is often impure. Nitrate of silver should always be given in pill, in which form, according to Dr. Powell, the system bears a dose three times as large as when given in solution. In the treatment of epilepsy, this physician recommends the exhibition at first of grain doses, to be gradually increased to six grains, three times a day. Its effects vary very much, owing no doubt to the salt being more or less decomposed by the substances used in preparing it in pill, or with which it comes in contact in the stomach. It should not be made up into pill with crumb of bread, as this contains common salt, but with some vegetable powder and mucilage. Considering that chloride of sodium is used in food, and exists, together with phosphates, in the secretions, and that free muriatic acid and albuminous fluids are present in the stomach, it is almost certain that, sooner or later, the whole of the nitrate of silver will be converted into the chloride, phosphate, and albuminate, compounds far less active than the original salt. The experiments of Keller, who analyzed the feces of patients under the use of this salt, confirm this view. Such being the inevitable result when the nitrate is given, the question arises how far it would be expedient to anticipate the change, and give the silver as a chloride ready formed. One of the authors of this work has tried the chloride in large doses, in two very unpromising cases of epilepsy, but without advantage.

According to Mialhe, nitrate of silver is immediately changed into the chloride upon entering the stomach, and this chloride is quickly converted into a soluble and readily absorbable double chloride, by combining with the chloride of sodium or potassium.

Nitrate of silver, in an over-dose, produces the effects of the corrosive poisons. The proper antidote is common salt, which acts by converting the poison into the insoluble chloride of silver.

ARGENTI NITRAS FUSUS. *U. S.* Argenti Nitras Fusum. *Dub.* Argenti Nitras. *Lond., Ed. Fused Nitrate of Silver. Lunar Caustic. Lapis Infernalis.*

"Take of Silver, in small pieces, *an ounce;* Nitric Acid [sp. gr. 1·42] *seven fluidrachms;* Distilled Water *two fluidounces.* Mix the Acid with the Water, and dissolve the silver in the mixture, on a sand-bath, with a gentle heat; then gradually increase the heat, and evaporate to dryness. Melt the resulting salt in a crucible over a gentle fire, and continue the heat until ebullition ceases; then immediately pour it into suitable moulds." *U. S.*

"Take of pure Silver *an ounce and a half;* Pure Nitric Acid [sp. gr. 1·5] *one fluidounce* [Imp. meas.]; Distilled Water *two fluidounces* [Imp. meas.]. Mix the Acid and Water, add the Silver, and dissolve it with the aid of a gentle heat; increase the heat gradually till a dry salt be obtained; fuse the salt in an earthenware or porcelain crucible, and pour the fused matter into iron moulds, previously heated, and greased slightly with tallow. Preserve the product in glass vessels." *Ed.*

"Take of Refined Silver *three ounces* [avoirdupois]; Pure Nitric Acid [sp. gr. 1·5] *two fluidounces* [Imp. meas.]; Distilled Water *five ounces* [avoird.]. Place the Silver in a flask, and, having poured upon it the Acid and Water, apply a gentle heat until the metal is dissolved. Transfer the solution to a porcelain capsule, decanting it off a heavy black powder which appears at the bottom of the flask, and, having evaporated it to dryness, raise the heat (in a dark room) until liquefaction is produced. Pour the melted Nitrate of Silver into a brass mould, furnished with cylindric cavities of the size of a goose quill, and which admits of being opened by a hinge, and, when the salt has concreted, remove it, and preserve it in well stopped vessels, rendered impervious to light." *Dub.*

The *London College* places fused nitrate of silver in the list of the Materia Medica.

The first step in the process for making fused nitrate of silver is the same as that for preparing the crystallized nitrate, namely, the solution of silver in nitric acid; but, instead of concentrating the solution so that crystals may form, it is at once evaporated to dryness, and the dry mass fused, and cast in cylindrical moulds. As the salt sinks into a common crucible, the fusion should be performed in one of porcelain, as recommended by the Edinburgh College, the size of which should be sufficient to hold five or six times the quantity of the dry salt operated on, in order to prevent its overflowing in consequence of the ebullition. Sometimes small portions of the liquid are spirted out, and the operator should be on his guard against this occurrence. When the mass flows like oil, it is completely fused, and ready to be poured into the moulds. These should be warmed, but not greased as directed by the Edinburgh College; as grease furnishes organic matter which partially decomposes the fused salt.

Properties. Fused nitrate of silver, as prepared by the above processes, is in the form of hard brittle sticks, of the size of a goose quill, at first white, but becoming gray or more or less dark under the influence of light, owing to the reduction of the silver, effected probably by organic matter, or sulphuretted hydrogen contained in the atmosphere. That the change, however, does not depend on the sole action of light has been proved by Mr. Scanlan, who finds that nitrate of silver, in a clean glass tube hermetically sealed, undergoes no change by exposure to light. The sticks often become dark-coloured and nearly black on the surface, and, when broken across, exhibit a crystalline fracture with a radiated surface. Fused nitrate of silver, when pure, is wholly soluble in distilled water; but even good samples of the fused salt will not totally dissolve, a very scanty black powder being left of reduced silver, arising probably from the salt having been exposed to too high a heat in fusion.

Impurities and Tests. Fused nitrate of silver is liable to contain free silver from having been exposed to too high a heat, the nitrates of lead and copper from the impurity of the silver dissolved in the acid, and nitrate of potassa from fraudulent admixture. Free silver will be left undissolved as a black powder, after the action of distilled water. A very slight residue of this kind is hardly avoidable; but, if there be much free silver, it will be shown by the surface of a fresh fracture of one of the sticks presenting an unusually dark-gray colour. (*Christison.*) The mode of detecting lead and copper is given under nitrate of silver. (See *Argenti Nitras.*) In order to detect nitre, a solution of the suspected salt should be precipitated by muriatic acid in excess, and sulphuretted hydrogen, to remove the silver, and other metals if they happen to be present. The filtered solution, if the salt be pure, will entirely evaporate by heat; if it contain nitre, this will be left, easily recognizable by its properties as a nitrate. This impurity sometimes exists in fused nitrate of silver in large amount, varying, according to different statements, from 10 to 75 per cent. According to Dr. Christison, it may be suspected if the sticks present a colourless fracture. A mode is given in the Edinburgh Pharmacopœia for testing fused nitrate of silver for impurity, without determining its nature. It depends upon the fact, that the pure salt requires for its conversion into chloride, a given quantity of a muriate or chloride; and that if a little less than this quantity be used to precipitate it, the supernatant liquid will be precipitable by more of the test. Now this will not be the case with the impure salt. In applying this test, the Edinburgh College directs that 29 grains of the salt should be dissolved in a fluidounce of distilled water acidulated with nitric acid, precipitated with a solution of 9 grains of muriate of ammonia, briskly agitated for a few seconds, and then allowed to rest. If the salt be impure, it will not be precipitated on the addition of more of the test. The similar test of the London Pharmacopœia of 1851 proceeds on the principle that a given weight of chloride of sodium is *fully* precipitated by an equivalent weight of the *pure* nitrate, and, consequently, that an equivalent weight of *impure* nitrate is not competent to produce a full precipitation. With this explanation, the following details of the test will be understood. A solution of six grains of chloride of sodium, after having been precipitated by seventeen grains of nitrate of silver and filtered, furnishes a solution which is not precipitated by more of the nitrate. The chief test of the U. S. Pharmacopœia is founded on the quantity of the chloride of silver which a given weight of the pure nitrate should furnish, when fully decomposed by chloride of sodium. Thus, it is stated that a solution, containing twenty-five grains of fused nitrate of silver, yields with chloride of sodium about twenty-one grains of a white precipitate, totally soluble in ammonia.

Medical Properties. Fused nitrate of silver should be restricted to external use. The medical properties of the salt, as an internal remedy, are given under the head of the *crystallized* nitrate. (See *Argenti Nitras.*) Externally applied the fused nitrate acts variously as a stimulant, vesicant, and escharotic, and may be employed either dissolved in water, or in the solid state. Dissolved to the extent of from one to five grains in a fluidounce of water, it is used for the purpose of stimulating indolent ulcers, and as an injection for fistulous sores. It is, in general, most conveniently applied to ulcers by means of a camel's hair brush. A drachm of the fused salt, dissolved in a fluidounce of water, forms an escharotic solution, which may often be resorted to with advantage. But fused nitrate of silver is most frequently employed in the solid state; and, as it is not deliquescent nor apt to spread, it forms the most manageable caustic that can be used. When thus employed, it is useful to coat the caustic, as recommended by M. Dumeril, by dipping it into melted engravers' sealing wax, which strengthens the stick, protects it from change, prevents it from staining the fingers, and

affords facilities for limiting the action of the caustic to particular spots. If it is desired, for example, to touch a part of the throat with the caustic, it is prepared by scraping off the wax, with a penknife, to a suitable extent from one end. Another way to strengthen the stick is to cast it around a platinum wire, as recommended by M. Chassaignac; or around a wick of cotton, according to the plan of M. Blatin. By the latter plan the fragments of the stick remain attached to one another. If the fused nitrate be rubbed gently over the moistened skin until it becomes gray, it generally vesicates, causing usually less pain than is produced by cantharides. The fused nitrate is also employed to destroy strictures of the urethra, warts and excrescences, fungous flesh, incipient chancres, and the surface of other ulcers Mr. Higginbottom considers its free application to ulcers, so as to cover them with an eschar, as an excellent means of expediting their cicatrization. He alleges that, if an adherent eschar be formed, the parts underneath heal before it falls off. The same writer recommends lunar caustic as a topical remedy in various external inflammations, but particularly in erysipelas, applied both to the inflamed and to the surrounding healthy parts. In some cases it is sufficient to blacken the cuticle; in others it is best to produce vesication. It has also been used with good effect, in the solid state, by Dr. Jewell in leucorrhœa, and by Ricord, Hannay, and others in the gonorrhœa of women. In these cases the pain produced is much less than would be expected. It has been recommended in gonorrhœa in the male, even in the acute stage, used in solution containing ten or twelve grains to the fluidounce; but, although some quick cures are well authenticated, the practice is hazardous. In smallpox it has been proposed by Bretonneau and Serres to cauterize each pustule after its top has been removed, on the first or second day of the eruption, in order to arrest its development and prevent pitting. The fused nitrate also forms an efficacious application to certain ulcerations of the throat, to different forms of porrigo of the scalp and other skin diseases, to punctured and poisoned wounds, and to chilblains, slowly rubbed over the moistened part. If, unexpectedly, the pain produced by its external use should be excessive, it may be immediately allayed by washing the parts with a solution of common salt, which acts by decomposing the caustic. The salt in impalpable powder, mixed with an equal weight of lycopodium, and used by inhalation, has been found beneficial in ulcerated sorethroat, laryngitis, bronchitis, and incipient phthisis, by Dr. W. M. Cornell, of Boston. (*Boston Med. and Surg. Journ.* Sept. 25, 1850.) It has also been used successfully in croup by Dr. Homans, of Boston, applied in solution to the larynx, either by injection or by means of a sponge. (*Am. Journ. of Med. Sci.*, April, 1854, p. 346.)

Pharm. Use. Fused nitrate of silver is employed by the Dublin College as a chemical agent for preparing Acidum Nitricum Purum.

Off. Prep. Argenti Oxydum. B.

ARGENTI OXIDUM. *U. S.* Argenti Oxydum. *Dub.* *Oxide of Silver.*

"Take of Nitrate of Silver *four ounces;* Distilled Water *half a pint;* Solution of Potassa *a pint and a half,* or a *sufficient quantity.* Dissolve the Nitrate of Silver in the Water, and to the solution add the Solution of Potassa, as long as it produces a precipitate. Wash the precipitate repeatedly with water until the washings are nearly tasteless. Lastly, dry the powder, and keep it in a well stopped bottle, protected from the light." *U. S.*

"Take of [fused] Nitrate of Silver *half an ounce* [avoirdupois]; Lime-water *half a gallon* [Imp. meas.], or *a sufficient quantity;* Distilled Water *half a pint* [Imp. meas.]. Dissolve the Nitrate of Silver in four ounces of the Distilled Water, and, having poured the solution into a bottle containing the Lime-water,

shake the mixture well, and then set it by till the sediment subsides. The supernatant solution being drawn off, let the sediment be placed upon a filter, and, when washed with the remainder of the Distilled Water, let it be dried at a heat not exceeding 212°, and preserved in a bottle." *Dub.*

Oxide of silver is a new officinal of the U.S. and Dublin Pharmacopœias. In the processes for making it, nitrate of oxide of silver is decomposed by potassa or lime, the oxide being precipitated, and nitrate of potassa or nitrate of lime, as the case may be, remaining in solution. When thus obtained the oxide is an olive-brown powder. If the potassa used is not wholly free from carbonic acid, the precipitated oxide of silver will be contaminated with some carbonate. According to Mr. Borland, of London, the carbonate is sometimes sold for the oxide. A third process for obtaining it is that of Gregory, which consists in boiling the moist, recently prepared chloride of silver with a very strong solution of caustic potassa (sp. gr. 1·25 to 1·30). In this case, by double decomposition, oxide of silver and chloride of potassium are formed. When thus prepared it is a very dense pure-black powder. Oxide of silver is very slightly soluble in water. Exposed to heat it gives out oxygen, and is wholly converted into metallic silver. It should not effervesce with acids. When its solution in nitric acid is precipitated by chloride of sodium in excess, the supernatant liquid is not discoloured by sulphohydrate of ammonia. The non-action of this test shows the absence of most foreign metals, especially copper and lead. Oxide of silver consists of one eq. of silver 108, and one of oxygen 8=116.

Medical Properties. This oxide has been proposed as a substitute for nitrate of silver, as having the therapeutic properties of the latter, without its escharotic effect, and objectionable power of discolouring the skin. It was first employed in medicine by Van Mons and Sementini. More recently it has been recommended by Mr. C. H. B. Lane, who considers it to act as a sedative. Mr. Lane has used it with more or less success in nausea, cardialgia, pyrosis, various painful affections of the stomach independent of organic lesion, dysentery, diarrhœa, night sweats without other obvious affection, dysmenorrhœa, menorrhagia, leucorrhœa, chronic enlargements of the uterus, attended with flooding, &c. The oxide appeared to exert a peculiar control over uterine fluxes. Some of the cases treated required the use of tonics, after the salutary influence of the oxide had been exerted. Dr. Golding Bird has also obtained favourable effects from the use of the oxide of silver, and confirms to a certain extent the results of Mr. Lane, especially as to its valuable powers in menorrhagia. Thus far no case of cutaneous discoloration has occurred, though Mr. Lane has given the oxide repeatedly for two months, and Dr. Bird in more than a hundred cases; in one for four months. Mr. Lane has observed one case in which repeated salivation occurred, and Dr. Bird several in which the gums were affected. But, in order to draw any inference from this result, the prescriber should be certain that the medicine is not contaminated with black oxide of mercury. In stomach disease, characterized by a glairy discharge instead of a watery one, this physician derived not the slightest benefit from the oxide, though he used it in thirty cases. In epilepsy it is supposed that the oxide will accomplish all that can be expected from the nitrate, with less risk to the stomach, and without incurring the danger of discolouring the skin. In tænia it has been used successfully in two cases by Mr. Whittel. The dose of oxide of silver is a grain, twice or thrice a day, given in pill. In no case did Mr. Lane carry the dose beyond six grains in the twenty-four hours. It has been used in the form of ointment, composed of from five to ten grains to the drachm of lard, as an application to venereal sores, and to the urethral membrane in gonorrhœa, smeared on a bougie. B.

ARSENICUM.

Preparations of Arsenic.

ACIDUM ARSENIOSUM PURUM. *Dub. Pure Arsenious Acid.*

"Take of Commercial White Oxide of Arsenic *any convenient quantity*. Place it in a Florence flask, the neck of which is made to pass into that of a second flask of larger size, and applying to the *former* a regulated heat, by suspending it beneath a semi-cylindric hood of sheet iron, a few inches above a small charcoal fire, cause the Arsenic to sublime into the *latter*. This sublimation should be conducted under a flue with a good draught, so as to protect the operator from inhaling any vapours which may escape being condensed." *Dub.*

The Dublin College, deeming the commercial white oxide of arsenic (*Acidum Arseniosum*, U. S., Lond.) not sufficiently pure for medicinal employment, has given the above formula for its purification. But, as the commercial oxide itself has undergone a second sublimation, this process is superfluous. The only precaution necessary to be taken, on the part of the apothecary, is to purchase the oxide in lump; for when in powder it is apt to be adulterated with chalk or sulphate of lime. The chemical, medical, and toxicological properties of this substance have been given under the head of *Acidum Arseniosum*.

Off. Prep. Liquor Arsenicalis. B.

LIQUOR ARSENICI CHLORIDI. *Lond. Solution of Chloride of Arsenic. De Valangin's Arsenical Solution.*

"Take of Arsenious Acid, broken into small pieces, *half a drachm;* Hydrochloric Acid *a fluidrachm and a half* [Imp. meas.]; Distilled Water *a pint* [Imp. meas.]. Boil the Arsenious Acid with the Hydrochloric Acid, mixed with an ounce of the Water, until it is dissolved; then add sufficient Water to make the solution accurately fill the measure of a pint [Imp. meas.]." *Lond.*

This new officinal of the London Pharmacopœia of 1851 is intended to be an imitation of De Valangin's arsenical solution, called by the inventor, who was a practitioner in London, *solutio solventis mineralis*. It was originally made by subliming three parts of arsenious acid with eight of common salt, and dissolving the product in a determinate quantity of diluted muriatic acid. The sublimation directed by De Valangin with common salt, had no effect on the arsenious acid, and, accordingly, his preparation may be considered to have been a solution of arsenious acid in muriatic acid, becoming probably terchloride of arsenic by the mutual decomposition of the acids.

In the London formula thirty grains of arsenious acid are dissolved in twenty Imperial fluidounces of the menstruum, that being the measure to which the preparation is ultimately brought. Hence each fluidounce contains a grain and a half of arsenious acid, or an equivalent quantity of terchloride.

Medical Properties. This arsenical solution appears to have considerable reputation in London as an alterative. It is chiefly employed in the treatment of chorea and lepra vulgaris. Dr. Farre, of London, states, as the result of his observation, that it effectually cures the worst forms of chorea. (Pereira, *Mat. Med.*, 3d ed., p. 670.) Dr. Pereira, who has used this solution on numerous occasions, bears testimony to its efficacy in the treatment of chorea and lepra, but has not satisfied himself of its superiority to Fowler's solution. It is said to be less apt to disturb the stomach; but it must be recollected that De Valangin's solution is only three-eighths as strong as that of Fowler, and yet is not given in larger doses. The average dose is five drops three times a day. Dr. Farre begins with three drops three times a day, increasing one drop each day,

until the dose reaches ten drops three times daily. Whenever the stomach becomes disordered, the medicine should be suspended; and when renewed, it must be given in the original dose. B.

ARSENICI IODIDUM. *U. S. Iodide of Arsenic.*

"Take of Arsenic *a drachm;* Iodine *five drachms.* Rub the Arsenic in a mortar until reduced to a very fine powder, free from metallic lustre; then add the Iodine, and rub them together till they are thoroughly mixed. Put the mixture into a small flask or a test-tube, loosely stopped, and heat it very gently until liquefaction occurs. Then incline the vessel in different directions, in order that any portion of the Iodine, which may have condensed on its inner surface, may be returned into the fused mass. Lastly, pour the melted Iodide on a porcelain slab, and, when it is cold, break it into pieces, and put it into a bottle, which is to be well stopped." *U. S.*

This iodide was introduced into the U. S. Pharmacopœia for the purpose of being used in preparing the solution of iodide of arsenic and mercury, described in the next article. It is made by the direct combination of its elementary constituents by the aid of a gentle heat.

Properties, &c. Iodide of arsenic is an orange-red, crystalline solid, entirely soluble in water, and wholly volatilized by heat. In composition it is considered to be a *teriodide,* consisting of one eq. of arsenic 75, and three of iodine 378·9=453·9. It has been used by Biett as an external application in corroding tubercular skin diseases. By the late Dr. A. T. Thomson it was given internally with advantage in lepra, impetigo, and diseases resembling cancer. Dr. F. C. Crane cured a case of what he considered cancer of the breast by its use for nearly eight months. The ointment used by Biett was composed of three grains of the iodide to an ounce of lard. The dose for internal exhibition is an eighth of a grain three times a day, given in pill or solution.

Off. Prep. Liquor Arsenici et Hydrargyri Iodidi. B.

LIQUOR ARSENICI ET HYDRARGYRI IODIDI. *U. S.* Arsenici et Hydrargyri Hydriodatis Liquor. *Dub. Solution of Iodide of Arsenic and Mercury. Solution of Hydriodate of Arsenic and Mercury. Donovan's Solution.*

"Take of Iodide of Arsenic, Red Iodide of Mercury, each, *thirty-five grains;* Distilled Water *half a pint.* Rub the Iodides with half a fluidounce of the Water, and, when they have dissolved, add the remainder of the Water, heat to the boiling point, and filter." *U. S.*

"Take of Pure Arsenic, in fine powder, *six grains;* Pure Mercury *sixteen grains;* Pure Iodine *fifty grains and a half;* Alcohol [sp. gr. 0·795] *half a fluidrachm* [Imp. meas.]; Distilled Water *nine ounces* [avoirdupois], or *a sufficient quantity.* Rub together the Arsenic, Mercury, Iodine, and Spirit, until a dry mass is obtained, and, having triturated eight ounces of the Water with this in successive portions, let the whole be transferred to a flask, and heated until it begins to boil. When cooled and filtered, let as much Distilled Water be added to it as will make the bulk of the solution exactly eight fluidounces and six drachms [Imp. meas.]." *Dub.*

This solution was introduced to the notice of the medical profession in 1839, by Mr. Donovan, of Dublin, as a therapeutic agent combining the medical virtues of its three ingredients, and has been adopted as an officinal preparation in the U. S. and Dublin Pharmacopœias of 1850. The formula of the U. S. Pharmacopœia is the simplified one of Prof. Procter, which consists essentially in dissolving equal weights of the teriodide of arsenic and biniodide (red iodide) of mercury in a measured quantity of distilled water. The proportion of equal weights corresponds nearly to single equivalents of the component iodides. The

Dublin formula is more complicated. In it the proper quantities of arsenic, mercury, and iodine are caused to unite by first rubbing them together with alcohol, and then boiling the product with distilled water, which is afterwards added, so as to give the whole a determinate bulk. The iodides of arsenic and mercury, formed by the trituration, are assumed by Mr. Donovan to become, by solution, hydriodates severally of arsenious acid (white oxide of arsenic), and of deutoxide of mercury (red precipitate); and the Dublin College name is formed on the supposition of this change.

Properties. This solution has a pale-yellow colour, and a slightly styptic taste. It is incompatible with laudanum, and the sulphate, muriate, and acetate of morphia. On the supposition that the preparation is an aqueous solution of iodides, it will contain them in the proportion of one eq. of teriodide of arsenic 453·9 to one of biniodide of mercury 454·6, which are nearly equal weights. On the theory of their conversion into hydriodates by solution, five eqs. of water 45 would be required, three for the arsenical teriodide, and two for the mercurial biniodide; and the result would be one eq. of arsenious acid 99, one of deutoxide of mercury 218, and five of hydriodic acid 636·5, the latter containing five eqs. of iodine 631·5. The solution here supposed would contain two and one-fifth times as much deutoxide of mercury as of arsenious acid.

Medical Properties. This preparation has been found decidedly useful as an alterative in the treatment of various diseases of the skin, such as the different forms of psoriasis, impetigo, porrigo, lepra, pityriasis, lupus, and venereal eruptions, both papular and scaly. In support of its efficacy in these affections, Mr. Donovan has adduced the testimony of a number of respectable practitioners, of Dublin and elsewhere, who have communicated to him the results of their experience. The disease in some of the cases cured had existed for a number of years. Dr. E. I. Taylor, of New York, has employed it in a number of cutaneous diseases, and finds that it produces more marked and prompt effects than the remedies usually resorted to in the treatment of lupus, rupia, psoriasis, and secondary venereal. (*Am. Journ. of Med. Sci., N. S.*, v. 319.) In two cases of uterine disease, characterized by patency of the os uteri and vascular turgescence of the cervix, and attended with lumbar and pelvic pains, Dr. Kirby of Dublin, afforded relief by the use of the solution. The dose is from five to twenty drops three times a day, given preferably in distilled water. The latter dose contains the twenty-fourth of a grain of arsenious acid, a little over the twelfth of a grain of deutoxide of mercury, and about a quarter of a grain of iodine. Dr. Taylor never exceeded the dose of five drops, three times a day. Sometimes the medicine deranges the stomach, confines the bowels, and produces headache, giddiness, and confusion of mind. When these effects are produced, it must be laid aside and a purgative administered. After an interval varying from ten days to three weeks, it may be resumed, but in a smaller dose. The treatment often requires to be persevered in for several months. Sometimes the medicine produces moderate salivation. By some practitioners, the solution, diluted with an equal bulk of water, was used with advantage as an external application to the ulcers or eruptions, at the same time that the medicine was given internally. For further information the reader is referred to the three papers of Mr. Donovan, contained in the *Dublin Journal of Med. Science*, for Nov. 1839, Sept. 1840, and Nov. 1842. B.

LIQUOR POTASSÆ ARSENITIS. *U. S.*, *Lond.* Liquor Arsenicalis. *Ed.*, *Dub.* *Solution of Arsenite of Potassa.* *Arsenical Solution.* *Fowler's Solution.*

"Take of Arsenious Acid, in small fragments, Pure Carbonate of Potassa, each, *sixty-four grains;* Distilled Water *a sufficient quantity;* Compound Spirit

of Lavender *half a fluidounce.* Boil the Arsenious Acid and Carbonate of Potassa in a glass vessel, with twelve fluidounces of Distilled Water, till the Acid is entirely dissolved. To the solution, when cold, add the Spirit of Lavender, and afterwards sufficient Distilled Water to make it fill exactly the measure of a pint." *U. S.*

"Take of Arsenious Acid, broken into small pieces, Carbonate of Potassa, each, *eighty grains;* Compound Tincture of Lavender *five fluidrachms* [Imp. meas.]; Distilled Water *a pint* [Imp. meas.]. Boil the Arsenious Acid and Carbonate of Potassa with half a pint of the Water, until they are dissolved. Add the Tincture to the cooled liquor, and, lastly, sufficient Distilled Water, that it may accurately fill a pint [Imp. meas.]." *Lond.*

The *Edinburgh* formula is substantially the same with the London, from which it injudiciously varies by ordering the arsenious acid in powder, and water instead of distilled water. In it the lavender preparation is misnamed "tincture," it being recognised as a "spirit" in the nomenclature of the Edinburgh College.

"Take of Pure Arsenious Acid; Pure Carbonate of Potash, each, *eighty-two grains;* Compound Tincture of Lavender, *half a fluidounce* [Imp. meas.]; Distilled Water *as much as is sufficient.* Introduce the Arsenious Acid and Carbonate of Potash into a flask containing half a pint of Water, and boil until a perfect solution is obtained. When this has cooled, add to it the Compound Tincture of Lavender, and as much Water as will make the bulk of the entire one pint [Imp. meas]. The specific gravity of this Solution is 1·013." *Dub.*

This preparation originated with the late Dr. Fowler, of Stafford, England, and was intended as a substitute for the celebrated remedy, known under the name of "the *tasteless ague drop.*" It is an arsenite of potassa dissolved in water, and is formed by the combination of the arsenious acid with the potassa of the carbonate, the carbonic acid being evolved. The name, therefore, by which it is designated in the United States and London Pharmacopœias, is obviously the most correct. The spirit of lavender is added to give it taste, in order to prevent its being mistaken for simple water. The United States preparation is of about the same strength as those of the London and Edinburgh Colleges; for, although one-fourth more acid and alkali is taken in the London and Edinburgh than in the U. S. formula, yet it is to be recollected that the Imperial pint is nearly one-fourth larger than the wine pint. The solution, according to the formula of the Dublin Pharmacopœia of 1850, is one-fortieth stronger, by reason of the injudicious direction to take eighty-two grains instead of eighty, to dissolve in the Imperial pint of twenty fluidounces. This formula is an amended one, and it is to be regretted that the Dublin College did not perceive the propriety of making the strength of its arsenical solution conform with that established for this preparation, of four grains of arsenious acid to the fluidounce.

In making this preparation, care should be taken that the arsenious acid is pure. This object is best secured by using the acid in small pieces instead of in powder. Sulphate of lime is a common adulteration in the acid, and if present will remain undissolved, and cause the solution to be weaker than it should be. Hence, if the arsenious acid does not entirely dissolve, the preparation must be rejected.

Properties. Solution of arsenite of potassa is a transparent liquid, having the colour, taste, and smell of the spirit of lavender. It has a strong alkaline reaction. It is decomposed by the usual reagents for arsenic, such as nitrate of silver, the salts of copper, lime-water, and sulphuretted hydrogen; and is incompatible with infusions and decoctions of cinchona. Before sulphuretted hydrogen will act, the solution must be acidulated with some acid, as the muriatic or acetic. If very long kept in flint glass, it is apt to suffer partial decomposition, exhaling a garlicky odour, and giving the inner surface of the bottle a metallic

lustre, owing to the lead of the glass being revived. (Canavan, *N. Y. Journ. of Pharm.*, i. 131.)

Medical Properties and Uses. This solution has the general action of the arsenical preparations on the animal economy, already described under the head of *Arsenious Acid*. Its liquid form makes it convenient for exhibition and gradual increase; and it is the preparation generally resorted to, when arsenic is given internally. It has been much employed in intermittent fever. Dr. Thomas D. Mitchell, of Philadelphia, has given the result of his experience, as to its efficacy and safety in this disease, when exhibited in the large dose of fifteen or twenty drops three times a day. It is a valuable resource in the intermittents of children, who are with difficulty induced to swallow bark or even sulphate of quinia. The late Dr. Dewees relates the case of a child only six weeks old, affected with a severe tertian, in which this solution was given with success. A fluidrachm was diluted with twelve fluidrachms of water; and of this six drops were given every four hours.

Fowler's solution appears to be peculiarly adapted to the treatment of several diseases. It has been employed with great success in lepra and other inveterate cutaneous affections. The late Dr. S. Calhoun published an account of five cases of nodes, successfully treated by it; and, in consequence of his success, Dr. Baer, of Baltimore, and the late Dr. Eberle gave it a trial in this affection, and obtained satisfactory results. Several cases of chorea, cured by this remedy, are reported by Mr. Martin, Mr. Slater, and Dr. Gregory, in the *Medico-Chirurgical Transactions* of London. Two interesting cures of periodical headache, performed by the solution, are related by the late Dr. Otto, of Philadelphia, in the fourth and fifth volumes of the *North American Med. and Surg. Journal*. Mr. H. Hunt found it useful in menorrhagia, but prefers the use of arsenious acid, as less apt to produce unpleasant effects, requiring the discontinuance of the remedy. (See *page* 23.) A diluted solution, in the proportion of a fluidrachm to the fluidounce of water, has been used with advantage as a topical application to foul ulcers.

Each fluidrachm of the solution contains half a grain of arsenious acid. The average dose for an adult is ten drops two or three times a day. For the peculiar effects which it produces in common with the other arsenical preparations, the reader is referred to the article on *Arsenious Acid*.

Duflos's antidote to the poisonous effects of Fowler's solution, and of the salts of the acids of arsenic generally, is the acetate of the sesquioxide of iron with excess of base, made by dissolving freshly precipitated sesquioxide in acetic acid to saturation, adding an equal quantity of the oxide to the solution, and diluting the whole with water to the consistence of cream. (See *page* 29.) B.

ATROPIA.

Preparation of Atropia.

ATROPIÆ SULPHAS. *Lond. Sulphate of Atropia.*

"Take of Diluted Sulphuric Acid *two fluidrachms;* Atropia *seven scruples and a half,* or *a sufficient quantity;* Distilled Water *half a fluidounce.* To the Acid previously mixed with the Water add gradually the Atropia to saturation. Filter the solution, and evaporate with a gentle heat so that crystals may form." *Lond.*

The London College prepares this salt exclusively for external use. Its properties and uses are those of its alkaline base, and are described under Belladonna. W.

BARYTA.

Preparations of Baryta.

BARII CHLORIDUM. *U. S.*, *Dub.* BARYTÆ MURIAS. *Ed.* *Chloride of Barium. Muriate of Baryta.*

"Take of Carbonate of Baryta, in small fragments, *a pound;* Muriatic Acid *twelve fluidounces;* Water *three pints.* Mix the Acid with the Water, and gradually add the Carbonate of Baryta. Towards the close of the effervescence apply a gentle heat, and, when the action has ceased, filter the liquor, and evaporate so that crystals may form when it cools." *U. S.*

The *Edinburgh College* gives two processes for obtaining this chloride; one in which the native carbonate of baryta, the other in which the native sulphate is employed. The process with the sulphate is as follows.

"Take of Sulphate of Baryta *two pounds;* Charcoal, in fine powder, *four ounces;* Pure Muriatic Acid *a sufficiency.* Heat the sulphate to redness, reduce it to fine powder, mix the charcoal with it thoroughly, heat the mixture in a covered crucible for three hours at a low white heat. Pulverize the product, put it gradually into five pints [Imp. meas.] of boiling water; boil for a few minutes; let it rest for a little over a vapour-bath; pour off the clear liquor, and filter it if necessary, keeping it hot. Pour three pints [Imp. meas.] of boiling water over the residuum, and proceed as before. Unite the two liquids; and, while they are still hot, or, if cooled, after heating them again, add Pure Muriatic Acid gradually so long as effervescence is occasioned. In this process the solutions ought to be as little exposed to the air as possible; and in the last step the disengaged gas should be discharged by a proper tube into a chimney or the ash-pit of a furnace. Strain the liquor, concentrate it, and set it aside to crystallize." *Ed.*

The *Dublin College* also obtains chloride of barium severally from the native carbonate and native sulphate, and by processes which are in principle the same as those above quoted.

When the carbonate of baryta is employed for obtaining chloride of barium, the reactions are exceedingly simple. The muriatic acid displaces the carbonic acid with effervescence; and, by reacting with the baryta, forms chloride of barium and water. A solution of chloride of barium being thus obtained, it yields crystals of the chloride by concentration and cooling. The reactions occurring in the process in which the sulphate is used are more complicated. The ignition with carbonaceous matter deoxidizes its constituents, converting it into sulphuret of barium, the oxygen escaping in combination with the carbon as carbonic oxide and acid. The sulphuret of barium, when dissolved in water, is decomposed on the addition of muriatic acid, sulphuretted hydrogen being evolved in large quantities, and chloride of barium formed in solution, from which, in the usual manner, the solid salt is obtained. The direction to discharge the sulphuretted hydrogen into a chimney, or the ash-pit of a furnace, is intended to provide for its decomposition by smoke; for if the gas is not disposed of in this or some similar way, it becomes exceedingly annoying to the operator.

Of the officinal processes, that in which the native carbonate is used is the simplest and most convenient; but the carbonate is comparatively a rare mineral; and as the sulphate in fine powder is a cheap article of commerce, being extensively used in the adulteration of white lead, it is almost always used for obtaining chloride of barium and the other barium compounds.

Properties. Chloride of barium is a permanent white salt, possessing a bitter and disagreeable taste. It crystallizes in rhombic tables with beveled edges. It

dissolves in about two and a half times its weight of cold water, and in a little more than its own weight at 222°, the boiling point of a saturated solution. It is scarcely soluble in absolute alcohol, but dissolves in rectified spirit. Alcohol, impregnated with it, burns with a yellow flame. When exposed to heat, it decrepitates and loses its water of crystallization, and at a red heat fuses. It is decomposed by the sulphates, oxalates, and tartrates, and the alkaline phosphates, borates, and carbonates; also by nitrate of silver, acetate and phosphate of mercury, and acetate of lead. When pure it does not deliquesce. Its solution is not affected by ammonia, which proves the absence of alumina and sesquioxide of iron, or by sulphuretted hydrogen, which shows that neither copper nor lead is present. After the whole of the barium has been precipitated by an excess of sulphuric acid, the supernatant liquid is shown to be free from lime by the non-action of carbonate of soda. Lime may be separated by the process of Dr. Wolcott Gibbs, which consists in adding to the solution of the chloride a small portion of the solution of hydrate of baryta, and then passing through it a current of carbonic acid, when the whole of the lime will be thrown down as a carbonate. (Wurtz, *N. Y. Journ. of Pharm.*, i. 164.) If strontia be present, an alcoholic solution of the salt will burn with a red flame. Like all the soluble salts of barium it is poisonous. It consists of one eq. of chlorine 35·42, one of barium 68·7, and two of water 18=122·12. It is used in medicine only in solution.

Off. Prep. Liquor Barii Chloridi; Quinæ Murias. B.

LIQUOR BARII CHLORIDI. *U. S.* Solutio Barytæ Muriatis. *Ed.* Barii Chloridi Liquor. *Dub.* *Solution of Chloride of Barium. Solution of Muriate of Baryta.*

"Take of Chloride of Barium *an ounce;* Distilled Water *three fluidounces.* Dissolve the Chloride of Barium in the Water and filter." *U. S.*

"Take of Muriate of Baryta *one drachm;* Distilled Water *one fluidounce* [Imp. meas.]. Dissolve the Salt in the Water." *Ed.*

The Dublin College dissolves the chloride in eight times its weight of distilled water, forming a solution having the sp. gr. 1·088, which is a little weaker than that of the Edinburgh College.

Chloride of barium, not being used in the solid state, is here dissolved for convenient exhibition. The U. S. solution is nearly a saturated one, and is probably too strong for convenient use. The Edinburgh and Dublin preparations are much weaker. The solution should be limpid and colourless; and, to make it so, the salt in crystals, and not in powder, should be employed.

Medical Properties and Uses. This solution is deobstruent and anthelmintic, and in large doses poisonous; its action, according to some, being analogous to that of arsenic. It was introduced into practice by Dr. Crawford as a remedy for cancer and scrofula. Its value in the latter disease has been particularly insisted on by Hufeland. This physician considers it to act more particularly on the lymphatic system, in the irritated states of which he esteems it a valuable remedy. Hence he recommends it in the scrofulous affections of delicate and irritable organs, such as the eyes, lungs, &c. In the commencement of scrofulous phthisis, he views it as one of the best remedies to which we can have recourse. It is employed also in diseases of the skin, in ulcers, and ophthalmia. The dose for an adult of the U. S. solution is about five drops, given twice or thrice a day, and gradually but cautiously increased, until it produces nausea, or some other sensible impression. When taken in an overdose it causes violent vomiting and purging, vertigo, and other dangerous symptoms. To combat its poisonous effects, recourse must be had immediately to a weak solution of sulphate of magnesia, which acts by converting the poison into the insoluble sulphate of baryta. If vomiting does not come on, it should be induced by tickling

the fauces, or by the administration of an emetic. A case of poisoning by three drachms of the solid salt taken by mistake for sulphate of magnesia, which was successfully treated with dilute sulphuric acid and castor oil, is reported by Dr. C. Wolf, a German physician. The chief symptoms were tormina and vomiting, weak and irregular pulse, cold extremities, weak voice, want of muscular power in the hands and feet, and paralysis of the left eyelid. B.

BISMUTHUM.

Preparation of Bismuth.

BISMUTHI SUBNITRAS. *U. S.*, *Dub.* BISMUTHI NITRAS. *Lond.* BISMUTHUM ALBUM. *Ed.* *Subnitrate of Bismuth. Nitrate of Bismuth. White Bismuth. Trisnitrate of Bismuth. White Oxide of Bismuth.*

"Take of Bismuth, in fragments, *an ounce;* Nitric Acid [sp. gr. 1·42] *two fluidounces;* Distilled Water *a sufficient quantity.* Mix a fluidounce of Distilled Water with the Nitric Acid, and dissolve the Bismuth in the mixture. When the solution is complete, pour the clear liquor into three pints of Distilled Water, and set the mixture by, that the powder may subside. Lastly, having poured off the supernatant liquid, wash the Subnitrate of Bismuth with Distilled Water, wrap it in bibulous paper, and dry it with a gentle heat." *U. S.*

"Take of Bismuth *an ounce;* Nitric Acid [sp. gr. 1·42] *a fluidounce and a half* [Imp. meas.]; Distilled Water *three pints* [Imp. meas.]. Mix a fluidounce of the Water with the Acid, and, having added the Bismuth, apply heat until it is dissolved. Add the solution to the rest of the Water, and strain the mixture through a cloth, in order to separate the powder. Wash this with distilled water, and dry it with a gentle heat." *Lond.*

"Take of Bismuth, in fine powder, *an ounce;* Nitric Acid [of commerce?] (D. 1·380) *a fluidounce and a half* [Imperial measure]; Water *three pints* [Imp. meas.]. Add the metal gradually to the acid, favouring the action with a gentle heat, and adding a very little Distilled Water so soon as crystals or a white powder may begin to form. When the solution is complete, pour the liquor into the Water. Collect the precipitate immediately on a calico filter, wash it quickly with cold water, and dry it in a dark place." *Ed.*

"Take of Bismuth, in small fragments, *two ounces* [avoirdupois]; Pure Nitric Acid *three fluidounces* [Imp. meas.]; Distilled Water *one gallon* [Imp. meas.]. Into the Acid, first diluted with three ounces of the Water, introduce the Bismuth in successive portions; and having, when the spontaneous action has ceased, applied for ten minutes a heat approaching that of ebullition, decant the solution off any particles of metal which may remain undissolved. Evaporate the solution at a gentle heat until it is reduced to two fluidounces, and then pour it into half a gallon of the Water. When the precipitate which forms has subsided, decant the supernatant liquid, and agitate the sediment with the remainder of the Water. After twelve hours again decant, and, having placed the precipitate on a filter, dry it at a temperature of 212°, and reduce it to powder." *Dub.*

When bismuth is added to dilute nitric acid, red fumes are copiously given off, and the metal, oxidized by the decomposition of part of the nitric acid, is dissolved by the remainder, so as to form a solution of the ternitrate of teroxide of bismuth. It is unnecessary to have the metal in powder, as it dissolves with great facility when added to the acid in fragments. When the solution is completed, the liquor should be added to the water, which should be distilled, and not the water to the solution, which is not so eligible a plan. Immediately on the contact of the solution with the water, four eqs. of the ternitrate are re-

solved into three eqs. of neutral nitrate of bismuth (generally called subnitrate) which precipitates, and one eq. of the 9-nitrate which remains in solution. $4(BiO_3,3NO_5)=3(BiO_3,NO_5)$ and $BiO_3,9NO_5$. In order to have a smooth light powder which is most esteemed, the precipitate should be washed and dried as speedily as possible.

Properties. Subnitrate of bismuth is a tasteless, inodorous, heavy powder, of a pure-white colour. It is slightly soluble in water, and readily so in the strong acids, from which it is precipitated by water. The fixed alkalies dissolve it sparingly, and ammonia more readily. It is darkened by hydrosulphuric acid gas, but not by exposure to light, unless it contains a little silver, or is subjected to the influence of organic matter. If it dissolves in nitric acid without effervescence, it contains no carbonate, and, if the nitric solution is not precipitated by dilute sulphuric acid, it is free from lead. It sometimes contains arsenic, which may be detected by acting on it with pure sulphuric acid, evaporating to dryness, dissolving in hot distilled water, and testing a part of the solution by Marsh's apparatus. By this method Lassaigne detected one-sixth of one per cent. of arsenic in a sample of subnitrate sold in Paris. By the earlier chemists it was called *magistery of bismuth*. The perfumers, by whom it is sold as a paint for the complexion, denominate it *pearl white*. It consists of one eq. of nitric acid 54, one of teroxide of bismuth 237, and one of water 9=300.

Medical Properties and Uses. This preparation is tonic and antispasmodic. It was originally introduced into practice by Dr. Odier, of Geneva, and has been subsequently employed with advantage both in this country and in Europe. It has been used in epilepsy, palpitation of the heart, and spasmodic diseases generally; but more particularly in various painful affections of the stomach, dependent on disordered digestion, such as cardialgia, pyrosis, and gastrodynia. Rayer employed it with great advantage in the diarrhœa occurring in phthisis and in typhus, and Aran recommends it in the obstinate diarrhœa which sometimes follows typhoid fever. Its use always blackens the stools, from the effect of the intestinal gases. The dose is five grains, gradually increased to twelve or fifteen, twice or thrice a day, and may be taken in pill, or mixed with an equal weight of aromatic powder. Dr. Pereira seldom commences with less than a scruple, and has repeatedly exhibited half a drachm. M. Monneret, who praises this remedy in gastro-intestinal affections attended with diarrhœa, never gives less than two or three drachms a day. He conceives that its operation is entirely local; but this view is combatted by Dr. Lussana, who believes it is sometimes absorbed. It never passes into the urine. In an over-dose it produces alarming gastric distress, nausea, vomiting, diarrhœa or constipation, colic, heat in the breast, slight rigors, vertigo, and drowsiness. The remedies are bland and mucilaginous drinks, and, in case of inflammation, bleeding by leeches or venesection, enemata, and emollient fomentations. B.

CALX.

Preparations of Lime.

LIQUOR CALCIS. *U.S., Lond., Dub.* Aqua Calcis. *Ed. Lime-water.*

"Take of Lime *four ounces;* Distilled Water *a gallon.* Upon the Lime, first slaked with a little of the Water, pour the remainder of the Water, and stir them together; then immediately cover the vessel, and set it aside for three hours. Keep the solution, together with the undissolved Lime, in stopped glass bottles, and pour off the clear liquor when wanted for use. Water free from saline or

other obvious impurity may be employed in this process, though not distilled." *U. S.*

The *London College* takes *half a pound* of lime, and *twelve pints* [Imperial measure] of distilled water, and proceeds as above directed.

"Take any convenient quantity of Water, pour a little of it over about a twentieth of its weight of Lime; when the Lime is slaked, add to it the rest of the Water in a bottle; agitate well; allow the undissolved matter to subside; pour off the clear liquor when it is wanted, replacing it with more water, and agitating briskly as before." *Ed.*

"Take of Fresh-burned Lime *two ounces* [avoirdupois]; Distilled Water *half a gallon* [Imperial measure]. Having slaked the Lime with a [fluid]ounce and a half of the Water, introduce it into a well-stopped bottle containing the remainder of the Water, and shake well for the space of five minutes. After twelve hours the excess of Lime will have subsided, and the clear Lime-water may be drawn off with a syphon as it may be required. When the entire of the solution has been withdrawn, it may be renewed by shaking the sediment at the bottom of the bottle with another half gallon of Water; and, if the Lime be pure, and the bottle be accurately stopped, this process may be successfully repeated three or four times." *Dub.*

A solution of lime in water is the result of these processes. By the slaking of the lime it is reduced to powder, and rendered more easily diffusible through the water. According to all the Pharmacopœias, the solution is to be kept in bottles with a portion of undissolved lime, which causes it always to be saturated, whatever may be the temperature, and to whatever extent it may be exposed to the air. If care be taken to have a considerable quantity of the solution in the bottle, and to avoid unnecessary agitation, the upper portion will always remain sufficiently clear for use. The direction of the Edinburgh College to replace by more water the clear liquid poured off, cannot, of course, be carried into effect indefinitely. By the absorption of carbonic acid, the lime is gradually converted into the carbonate, and thus rendered insoluble. The employment of distilled water as the solvent may seem a useless refinement; and it certainly is unnecessary when pure spring or river water is attainable; but in many places the common water is very impure, and wholly unfit for a preparation, one of the most frequent uses of which is to allay irritation of stomach. Water dissolves but a minute proportion of lime, and, contrary to the general law, less when hot than cold. Hence the propriety of employing cold water in the process. According to Mr. Phillips, a pint of water (the wine pint of the U. S. Ph.) at 212° dissolves 5·6 grains of lime, at 60°, 9·7 grains, and at 32°, 11·0 grains. When a cold saturated solution is heated, a deposition of lime takes place.

Properties. Lime-water is colourless, inodorous, and of a disagreeable alkaline taste, changes vegetable blues to green, and forms an imperfect soap with oils. Exposed to the air it attracts carbonic acid, and becomes covered with a pellicle of insoluble carbonate of lime, which, subsiding after a time, is replaced by another, and so on successively till the whole of the lime is exhausted. Hence the necessity of keeping lime-water either in closely corked bottles which should be full, or, what is more convenient, in bottles with an excess of lime.

Medical Properties and Uses. Lime-water is antacid, tonic, and astringent, and is very usefully employed in dyspepsia with acidity of stomach, diarrhœa, diabetes, and gravel attended with superabundant secretion of uric acid. Mixed with an equal measure of milk, which completely covers its offensive taste, it is one of the best remedies in our possession for nausea and vomiting dependent on irritability of stomach. We have found a diet exclusively of lime-water and milk to be more effectual than almost any other plan of treatment in dyspepsia accompanied with vomiting of food. In this case, one part of the solution to two or three parts of milk is usually sufficient. Lime-water is also thought to

be useful by dissolving the intestinal mucus in cases of worms, and in other complaints connected with an excess of this secretion. Externally it is employed as a wash in tinea capitis and scabies, as an application to foul and gangrenous ulcers, as an injection in leucorrhœa and ulceration of the bladder or urethra, and, mixed with linseed or olive oil, as a liniment in burns and scalds. The dose is from two to four fluidounces taken several times a day. When employed to allay nausea, it is usually given in the dose of a tablespoonful mixed with the same quantity of new milk, and repeated at intervals of half an hour, an hour, or two hours. If too long continued it debilitates the stomach. Lime-water is used by the Dublin College in the preparation of Oxide of Silver.*

CALCIS CARBONAS PRÆCIPITATUS. *U. S.* CALCIS CARBONAS PRÆCIPITATUM. *Dub.* *Precipitated Carbonate of Lime.*

"Take of Solution of Chloride of Calcium *five pints and a half;* Carbonate of Soda *six pounds;* Distilled Water *a sufficient quantity.* Dissolve the Carbonate of Soda in six pints of Distilled Water. Heat this solution and the solution of Chloride of Calcium, separately, to the boiling point, and mix them. After the precipitate has subsided, pour off the supernatant liquid, wash the precipitate repeatedly with Distilled Water, and dry it on bibulous paper." *U. S.*

"Take of Chloride of Calcium *five ounces* [avoirdupois]; Crystals of Commercial Carbonate of Soda *thirteen ounces* [avoirdupois]; Boiling Water *two quarts* [*half a gallon*, Imperial measure]. Dissolve each salt in a quart of the Water, mix the two solutions, and, when the precipitate has subsided, draw off the supernatant liquor. Transfer the sediment to a calico filter, and wash it with boiling hot distilled water, until the washings cease to give a precipitate with nitrate of silver. Finally, dry the product at a temperature not exceeding 212°." *Dub.*

These processes do not essentially differ. In each a mutual interchange of principles takes place, resulting in the production of chloride of sodium which remains in solution, and carbonate of lime which is deposited. Any peculiar advantage which the preparation may possess must depend on the minute division of its particles. According to Dr. Bridges, this effect is best obtained by employing the solutions at the boiling temperature, a precaution which is observed in both the present officinal processes. (*Am. Journ. of Pharm.*, xvi. 163.) When properly made, it is a very pure carbonate of lime, in the form of a very fine white powder, free from grittiness, insoluble in water, but wholly soluble in dilute muriatic acid with copious effervescence. These properties serve to distinguish it from sulphate of lime, with which it is sometimes adulterated. For ordinary use, it probably has no such superiority over prepared chalk as to counterbalance its greater expensiveness. It is said to be preferred by some to chalk in the preparation of tooth-powders. It is frequently sold in the shops under the name of *creta præcipitata.* W.

* *Syrup of Lime.—Saccharate of Lime.* Under the latter name a preparation has been introduced into notice, made by saturating pure syrup with lime, and filtering. The sugar forms a soluble compound with the lime, large quantities of which are dissolved by the syrup. The syrup remains perfectly transparent, and is in no degree disturbed by dilution with water. It has a decidedly alkaline and even caustic taste, and should always be largely diluted when administered. It was first prepared by M. Beral; and its practical use was originally suggested by Dr. Capitaine, of Paris. Trousseau has employed it in the chronic diarrhœa of infants, and recommends it as an addition, in very small proportion, to the milk employed as a diet for children liable to this complaint. For this purpose he adds about eight grains of the syrup to the quart of milk. He gives the saturated syrup of lime to a child in the quantity of fifteen or thirty grains in the course of the day; to an adult, in five times the quantity. (*Trait. de Thérap.*, 4e ed., i. 317, and 321.)—*Note to the tenth edition.*

CRETA PRÆPARATA. *U. S., Lond., Ed., Dub. Prepared Chalk.*

"Take of Chalk *a convenient quantity.* Add a little water to the Chalk, and rub it into a fine powder. Throw this into a large vessel nearly full of water, stir briskly, and, after a short interval, pour the supernatant liquor, while yet turbid, into another vessel. Repeat the process with the chalk remaining in the first vessel, and set the turbid liquor by, that the powder may subside. Lastly, pour off the water, and dry the powder." *U. S.*

The *London College* places this preparation in the Materia Medica catalogue. The process of the *Edinburgh College* is essentially the same as that of the United States Pharmacopœia. The College directs the chalk to be powdered in a mortar, and orders it, after having been prepared, to be dried on a filter of linen or calico.

"Take of Chalk *one pound;* Water *a sufficient quantity.* Reduce the Chalk to a fine powder, and, having triturated this in a large mortar with as much water as will give it the consistence of cream, fill the mortar with water, and stir well, giving the whole a circular motion. Allow the mixture to stand for fifteen seconds, and then decant the milky liquid into a large vessel. Triturate what remains in the mortar, adding as much water as was previously used, and, after allowing it to settle for fifteen seconds, again decant, and let this process be repeated several times. Let the fine sediment which subsides from the decanted liquids be transferred to a calico filter, and dried at a temperature not exceeding 212°." *Dub.*

The object of these processes is to reduce chalk to a very fine powder. The mineral, previously pulverized, is rubbed with a little water upon a porphyry slab, by means of a rubber of the same material, and, having been thus very minutely divided, is agitated with water, which upon standing a short time deposits the coarser particles, and, being then poured off, slowly lets fall the remainder in an impalpable state. The former part of the process is called *levigation*, the latter *elutriation*. The soft mass which remains after the decanting of the clear liquor, is made to fall upon an absorbent surface in small portions, which when dried have a conical shape. Practically, prepared chalk is generally made on the large scale from *whiting* by the manufacturer. For the particulars of the process the reader is referred to the *Pharmaceutical Journal and Transactions*, viii. 416.

Medical Properties and Uses. This is the only form in which chalk is used in medicine. It is an excellent antacid; and, as the salts which it forms in the stomach and bowels, if not astringent, are at least not purgative, it is admirably adapted to diarrhœa accompanied with acidity. It is also sometimes used in acidity of stomach attending dyspepsia and gout, when a laxative effect is to be avoided; is one of the best antidotes for oxalic acid; and has been recommended in rachitis. In scrofulous affections it may sometimes do good by forming soluble salts with acid in the primæ viæ, and thus finding an entrance into the blood-vessels. It is frequently employed as an application to burns and ulcers, which it moderately stimulates, while it absorbs the ichorous discharge, and thus prevents it from irritating the diseased surface, or the sound skin. It is given internally in the form of powder, or suspended in water by the intervention of gum Arabic and sugar. (See *Mistura Cretæ.*) The dose is from ten to forty grains or more.

Pharm. Uses. Prepared chalk is used by one or another of the Pharmacopœias in the preparation of Citric Acid, Tartaric Acid, Chloride of Zinc, Solution of Chloride of Zinc, and Sulphate of Zinc.

Off. Prep. Confectio Aromatica; Hydrargyrum cum Cretâ; Mistura Cretæ; Pulvis Cretæ Compositus; Trochisci Cretæ; Unguentum Plumbi Compositum.

W.

TESTA PRÆPARATA. *U. S. Prepared Oyster-shell.*

"Take of Oyster-shell *a convenient quantity.* Free it from extraneous matter, wash it with boiling water, and reduce it to powder; then prepare it in the manner directed for chalk." *U. S.*

Prepared oyster-shell differs from prepared chalk in containing animal matter, which, being very intimately blended with the carbonate of lime, is supposed by some physicians to render the preparation more acceptable to a delicate stomach. It is given as an antacid in diarrhœa, in the dose of from ten to forty grains or more, frequently repeated. A preparation has been introduced, within a few years, into use in this country under the name of *Castillon's powders*, consisting of sago, salep, and tragacanth, each, in powder, *a drachm*, prepared oyster-shell *a scruple*, and sufficient cochineal to give colour to the mixture. A drachm of this is boiled in a pint of milk, and the decoction used *ad libitum* as a diet in chronic bowel affections. W.

LIQUOR CALCII CHLORIDI. *U. S. Dub.* Calcis Muriatis Solutio. *Ed. Solution of Chloride of Calcium. Solution of Muriate of Lime.*

"Take of Marble, in fragments, *nine ounces;* Muriatic Acid *a pint;* Distilled Water *a sufficient quantity.* Mix the Acid with half a pint of the Distilled Water, and gradually add the Marble. Towards the close of the effervescence apply a gentle heat, and, when the action has ceased, pour off the clear liquor and evaporate to dryness. Dissolve the residue in its weight and a half of Distilled Water, and filter the solution." *U. S.*

The *Edinburgh College* dissolves *eight ounces* of muriate of lime (chloride of calcium) in *twelve fluidounces* (Imp. meas.) of water. The *Dublin College* dissolves *three ounces* (avoirdupois) of the salt in *twelve fluidounces* of distilled water, filters, and states the sp. gr. of the solution at 1·225.

By the U. S. process chloride of calcium is first formed, and then, as in the other processes, is dissolved in a certain proportion of water. The U. S. and Edinburgh preparations agree very nearly in strength, containing 1 part of the chloride in about 2·5 parts of the solution. That of the Dublin College is only half as strong, containing 1 part of the chloride in 5 of the solution.

The solution of chloride of calcium has a disagreeable, bitter, acrid taste. It is decomposed by sulphuric acid and the soluble sulphates; by potassa, soda, and their carbonates; by carbonate of ammonia, tartrate of potassa and soda, nitrate of silver, nitrate and acetate of mercury, and acetate of lead. The mode of preparing chloride of calcium, and its chemical properties, are detailed under the head of *Calcii Chloridum* in the first part of this work.

Medical Properties and Uses. Chloride of calcium is considered tonic and deobstruent, and is said to promote the secretion of urine, perspiration, and mucus. It was first brought into notice as a remedy by Fourcroy, and was at one time much used in scrofulous diseases and goitre. It still continues to be a favourite with some physicians, but is less employed than formerly. It has been especially recommended in tabes mesenterica. Cazenave has employed it advantageously in chronic eczema and impetigo, when connected with a lymphatic temperament. When too largely taken it sometimes occasions nausea, vomiting, and purging, and in excessive doses may even produce fatal effects; but it is a much safer remedy than chloride of barium, which has been recommended in the same complaints. The dose of the solution is from thirty minims or drops to a fluidrachm, to be repeated twice or three times a day, and gradually increased to two, three, or even four fluidrachms. It may be given in milk or sweetened water.

Off. Prep. Calcis Carbonas Præcipitatus. W.

CALCIS CHLORINATÆ LIQUOR. *Dub. Solution of Chlorinated Lime.*

"Take of Chlorinated Lime *half a pound* [avoirdupois]; Water *half a gallon* [Imperial measure]. Blend well the Water and Chlorinated Lime by trituration in a large mortar, and, having transferred the mixture to a stoppered bottle, let it be well shaken several times for the space of three hours. Pour out now the contents of the bottle on a calico filter, and let the solution which passes through be preserved in a well-stopped bottle. The sp. gr. of this liquid is 1·035." *Dub.*

For the properties and uses of this preparation see *Calx Chlorinata, page* 154. Its strength must vary, according to the quality of the chlorinated lime employed. It is one of the best antidotes for hydrosulphuric acid, hydrosulphate of ammonia, sulphuret of potassium, and hydrocyanic acid. The dose for internal use is from twenty minims to a fluidrachm. For external application it may be diluted with twice its bulk of water, or may be used of the full strength in some cutaneous affections.

The Dublin College uses it in the preparation of Acetate of Zinc and Solution of Chloride of Zinc. W.

CALCIS PHOSPHAS PRÆCIPITATUM. *Dub. Precipitated Phosphate of Lime.*

"Take of Ox-bones, burned to whiteness in a clear fire, *four ounces* [avoirdupois]; Pure Muriatic Acid *six fluidounces;* Distilled Water *one quart* [two pints, Imperial measure]; Solution of Ammonia *eleven fluidounces*, or *as much as may be sufficient.* Reduce the Calcined Bones to a fine powder, and digest upon this the Acid, diluted with a pint of the Water, until it is dissolved. To the solution, first cleared (if necessary) by filtration, add the remainder of the water, and then the Solution of Ammonia, until the mixture acquires an alkaline reaction, and, having collected the precipitate upon a calico filter, let it be washed with boiling distilled water as long as the liquid which passes through gives rise to a precipitate, when permitted to drop into a solution of nitrate of silver acidulated with nitric acid. The washed product should now be dried by exposing it for some days on porous bricks to a warm atmosphere." *Dub.*

The muriatic acid dissolves the phosphate of lime of the bones, and lets it fall on the addition of ammonia, in a state of minute division. The ablution is intended to free it from any adhering muriate of ammonia. The salt thus obtained is, for the sake of distinction, called *bone-phosphate of lime.* It is in the form of a white powder, without taste or smell, insoluble in water, but very soluble in nitric, muriatic, and acetic acids, from which it is precipitated unchanged on the addition of ammonia. By an intense heat it is fused, but is not otherwise changed. It consists, according to Mitscherlich, of one equivalent of phosphoric acid and three of lime.

The chemical characteristics of bone-phosphate of lime, besides those mentioned, are that with its solution in dilute nitric acid, oxalate of ammonia produces a white precipitate of oxalate of lime, and acetate of lead a white precipitate of phosphate of lead; and, if the nitric solution be neutralized as far as possible without causing a permanent precipitate of phosphate of lime, ammoniacal nitrate of silver throws down from it a lemon-yellow precipitate of phosphate of silver. (*Christison's Dispensatory.*)

Medical Uses. In the form of burnt hartshorn, phosphate of lime formerly enjoyed a brief popularity in the treatment of rickets, and mollities ossium, in which its use seemed to be indicated upon obvious chemical grounds. It has recently been again brought into notice, in consequence of the suggestion by Benecke (*London Lancet*, July, 1851), that, as it is essential in animals as well as plants to the formation of cells, it might be found useful in certain pathological

states of the system characterized by defective nutrition, such as the scrofulous affections. Upon considerations of this kind, the late Dr. W. Stone, of New Orleans, was induced to employ it in cases of scrofulous ulceration, phthisis, &c., and with considerable supposed advantage. (See *St. Louis Med. and Surg. Journ.*, x. 38.) Subsequently, it has been used by other practitioners, and, in connexion with other phosphates, as those of iron, soda, and potassa, has acquired no little reputation in different forms of scrofula and phthisis. When, however, it is considered that, in ordinary food, there is more of the phosphates than the system has need of, so that they are constantly escaping with the stools; and that in those very disorders in which they are supposed to be indicated they are not unfrequently in excess in the blood and urine, in consequence probably of the rapid disintegration of the tissues, it would seem doubtful whether the want, in scrofulous cases, is as much that of materials for cells as that of due power to appropriate those materials. In the reported cases, the phosphate of lime has generally been administered in connexion with cod-liver oil or other tonics; to which, there is reason to believe, any benefit experienced is more truly ascribable than to the phosphate. In two of Dr. Stone's cases the good effects began to be experienced at the period when they might have been expected from the oil alone. Phosphate of lime, though insoluble in water, is probably in general more or less soluble in the gastric liquids, in consequence of the acid present in them; and, if desirable, it may readily be administered in solution by the addition of one of the acids mentioned in the above account of its chemical properties. The dose is from ten to thirty grains. W.

CARBO ANIMALIS.

Preparation of Animal Charcoal.

CARBO ANIMALIS PURIFICATUS. *U.S., Ed., Dub. Purified Animal Charcoal.*

"Take of Animal Charcoal *a pound;* Muriatic Acid, Water, each, *twelve fluidounces.* Pour the Muriatic Acid, previously mixed with the Water, gradually upon the Charcoal, and digest with a gentle heat for two days, occasionally stirring the mixture. Having allowed the undissolved portion to subside, pour off the supernatant liquor, wash the charcoal frequently with water until it is entirely free from acid, and dry it." *U. S.*

The *Edinburgh* formula is essentially the same as that of the U. S. Pharmacopœia.

"Take of Ivory Black *five pounds* [avoirdupois]; Muriatic Acid of Commerce *three pints* [Imp. meas.]; Water *three gallons and three pints* [Imp. meas.]; Distilled Water *as much as is necessary.* To the Acid, diluted with three pints of Water, gradually add the Ivory Black, and digest, with repeated stirring, at a gentle heat for twenty-four hours. Pour on now a gallon of Water, and when, after the mixture has been well agitated, the insoluble matters have subsided, remove the clear solution by decantation, or the syphon. Let this be done a second and a third time. Place now the black sediment on a calico filter, and wash it with Distilled Water, until the washings cease to give a precipitate with nitrate of silver. Finally, let the product be dried in a stove or oven, a gentle heat being at first applied, which must be finally raised to between 300° and 400°." *Dub.*

Animal charcoal, as it is made by charring bones, necessarily contains bone-phosphate and carbonate of lime, the presence of which does no harm in some decolorizing operations; but, in delicate chemical processes, these salts would be dissolved or decomposed, and thus be a source of impurity. It is on this account

that animal charcoal requires to be purified from the calcareous salts which it contains; and this is accomplished by dilute muriatic acid, which dissolves the phosphate and decomposes the carbonate.

Purified animal charcoal is a dark brownish-black powder. If it contain carbonate of lime, muriatic acid will cause effervescence, and the solution obtained will give a precipitate with carbonate of ammonia; and if phosphate of lime be present, the acid will dissolve this salt and yield it as a precipitate on the addition of ammonia. The Edinburgh College directs purified animal charcoal to be tested by incinerating it with its volume of red oxide of mercury; when, if good, it will be dissipated with the exception of a scanty ash.

It has been shown by Mr. Warington that bitter vegetable substances, including the organic alkalies, are removed from solution by passing through *purified* animal charcoal, especially when the action is assisted by heat. M. Weppen finds that a similar effect is produced by it in removing resins from tinctures, tannic acid and bitter principles from astringent and bitter infusions, and certain metallic salts from their solutions. Purified animal charcoal, thus employed, has been resorted to by M. Lebourdais as a means of obtaining the active principles of plants. A decoction or infusion of the plant is either boiled with or filtered through the charcoal, which takes up, more or less completely, the bitter and colouring principles. The charcoal is then washed and dried, and treated with boiling alcohol, which dissolves the principles taken up. Finally, the alcohol is distilled off, and the principles are obtained in a separate state. In this way digitalin, ilicin, scillitin, colombin, colocynthin, arnicina, strychnia, quinia, and other principles have been obtained by M. Lebourdais. (*Chem. Gaz.*, Nov. 15, 1848.) In relation to the method of M. Lebourdais for extracting the active principles of plants, see a paper by Mr. J. S. Cobb, in the *Am. Journ. of Pharm.* for July 1851, from the London *Pharm. Journ. and Trans.* Dr. A. B. Garrod has proposed purified animal charcoal as an antidote to vegetable and animal poisons, with which it appears to combine. According to his experiments, common bone-black has not one-fifth of the power of the purified substance; and vegetable charcoal and lamp-black are nearly or quite useless in counteracting the effects of poisons. The amount of the antidote proposed by Dr. Garrod is half an ounce for each grain of a vegetable organic alkali. Dr. Alfred Taylor deems the results of Dr. Garrod inconclusive. Dr. B. H. Rand, of Philadelphia, has made some interesting observations in relation to the antidotal powers of purified animal charcoal, and has proved by experiment that poisonous doses of the strongest vegetable poisons may be swallowed with impunity, if taken mixed with that substance. (*Med. Exam.*, Sept. 1848.)

Pharm. Uses. It is employed as a decolorizing agent in preparing Aconitia, Morphia, Morphiæ Hydrochloras, Quinæ Sulphas, Strychnia, and Veratria. When used for this purpose, its power of absorbing the vegetable organic bases should not be overlooked; as it may be a source of considerable loss. B.

CATAPLASMATA.

Cataplasms.

Cataplasms or poultices are moist substances intended for external application, of such a consistence as to accommodate themselves accurately to the surface to which they are applied, without being so liquid as to spread over the neighbouring parts, or so tenacious as to adhere firmly to the skin. As they are in this country scarcely ever prepared by the apothecary, they were not deemed by the compilers of the United States Pharmacopœia proper objects for officinal direction. W.

CATAPLASMA CARBONIS. *Lond.* *Charcoal Cataplasm.*

"Take of boiling Water *ten fluidounces;* Bread *two ounces;* powdered Flaxseed *ten drachms;* powdered Charcoal *three drachms.* Macerate the Bread with the Water for a little while near the fire; then mix, and gradually add the flaxseed, stirring so as to make a soft cataplasm. With this mix two drachms of the Charcoal, and sprinkle the rest upon the surface." *Lond.*

Charcoal, recently prepared, has the property of absorbing those principles upon which the offensive odour of putrefying animal substances depends. In the form of poultice, it is an excellent application to foul and gangrenous ulcers, correcting their fetor, and improving the condition of the sore. It should be frequently renewed. W.

CATAPLASMA CONII. *Lond.* *Hemlock Cataplasm.*

"Take of boiling Water *ten fluidounces;* powdered Flaxseed *four ounces and a half,* or *a sufficient quantity;* Extract of Hemlock *an ounce.* To the Water gradually add the Flaxseed, constantly stirring, so as to make a Cataplasm. Upon this spread the Extract previously softened with water." *Lond.*

This cataplasm may be advantageously employed as an anodyne application to cancerous, scrofulous, syphilitic, and other painful ulcers: but its liability to produce narcotic effects, in consequence of the absorption of the active principle of the hemlock, should not be overlooked. W.

CATAPLASMA FERMENTI. *Lond.* *Yeast Cataplasm.*

"Take of Yeast, Water heated to 100°, each, *five fluidounces;* Wheat Flour *a pound.* Mix the Yeast with the Water, and add the Flour, stirring so as to make a Cataplasm. Place this near the fire until it begins to swell up." *Lond.*

By exposing a mixture of yeast and flour to a gentle heat, fermentation takes place, and carbonic acid gas is extricated, which causes the mixture to swell, and is the source of its peculiar virtues. The yeast cataplasm is gently stimulant, and is sometimes applied with much benefit to foul and gangrenous ulcers, the fetor of which it corrects, while it is supposed to hasten the separation of the slough. W.

CATAPLASMA LINI. *Lond.* *Flaxseed Cataplasm.*

"Take of boiling Water *ten fluidounces;* Flaxseed, powdered, *four ounces and a half,* or *a sufficient quantity.* Add gradually the Flaxseed to the Water, constantly stirring, so as to make a Cataplasm." *Lond.*

The flaxseed meal which remains after the expression of the oil has sometimes been employed; but that which has not been submitted to pressure is decidedly preferable, and answers an excellent purpose when mixed with boiling water, without other addition, as in the London cataplasm. Fresh lard or olive oil, spread upon the surface of the poultice, serves to prevent its adhesion to the skin, and to preserve its softness.

The use of this and other emollient cataplasms is to relieve the tense condition of the vessels in inflammation, and to promote suppuration. They act simply by their warmth and moisture. The one most extensively employed, perhaps because its materials are always at hand, is that prepared by heating together milk and the crumb of bread. The milk should be quite sweet, and fresh lard should be incorporated with the poultice. Mush made with the meal of Indian corn also forms an excellent emollient cataplasm. W.

CATAPLASMA SINAPIS. *Lond.* *Mustard Cataplasm.*

"Take of boiling Water *ten fluidounces;* Flaxseed, Mustard [seed], each in powder, *two ounces and a half,* or *a sufficient quantity.* Add the powders, previously mixed together, gradually to the Water, stirring so as to make a cataplasm." *Lond.*

The simplest and most effectual mode of preparing a mustard poultice, is to mix the powdered mustard of the shops with a sufficient quantity of warm water to give it a due consistence. When a weaker preparation is required, an equal portion or more of rye or wheat flour should be added. Vinegar never increases its efficiency, and, in the case of the black mustard seed, has been ascertained by MM. Trousseau and Blanc to diminish its rubefacient power. A boiling temperature is also injurious by interfering with the development of the volatile oil or acrid principle. (See *Sinapis.*)

These poultices are frequently called *sinapisms.* They are powerfully rubefacient, exciting a sense of warmth in a few minutes, and usually becoming insupportably painful in less than an hour. When removed, they leave the surface intensely red and burning; and the inflammation frequently terminates in desquamation, or even blistering, if the application has been too long continued. Obstinate ulcers and gangrene also sometimes result from the protracted action of mustard, especially on parts possessed of little vitality. As a general rule, the poultice should be removed when the patient complains much of the pain; and in cases of insensibility should not, unless greatly diluted, be allowed to remain longer than one, or at most two hours; as violent inflammation, followed by obstinate ulceration, is apt to occur upon the establishment of reaction in the system. In children also particular care is necessary to avoid this result. The poultice should be thickly spread on linen, and may be covered with gauze or unsized paper in order to prevent its adhesion to the skin. If hairs are present they should be removed by the razor. Sinapisms may be employed in all cases in which it is desirable to produce a speedy and powerful rubefacient impression. W.

CATAPLASMA SODÆ CHLORINATÆ. *Lond.* *Cataplasm of Chlorinated Soda.*

"Take of boiling Water *six fluidounces;* Flaxseed, in powder, *four ounces and a half;* Solution of Chlorinated Soda *two fluidounces.* Add the Flaxseed gradually to the Water, constantly stirring; then mix in the Chlorinated Soda." *Lond.*

This is an excellent application to sloughing and other fetid ulcers, to correct the smell, and afford a moderate stimulation. W.

CERATA.

Cerates.

These are unctuous substances consisting of oil or lard, mixed with wax, spermaceti, or resin, to which various medicaments are frequently added. Their consistence, which is intermediate between that of ointments and of plasters, is such that they may be spread at ordinary temperatures upon linen or leather, by means of a spatula, and do not melt or run when applied to the skin. In preparing them, care should usually be taken to select the oil or lard perfectly free from rancidity. The liquefaction should be effected by a very gentle heat, which may be applied by means of a water-bath; and during the refrigeration the mixture should be well stirred, and the portions which solidify on the sides of the vessel should be made to mix again with the liquid portion, until the whole assumes the proper consistence. When a large quantity is prepared, the mortar, or other vessel into which the mixture may be poured for cooling, should be previously heated by means of boiling water. W.

CERATUM CALAMINÆ. *U. S., Lond., Ed.* *Calamine Cerate, Turner's Cerate.*

"Take of Prepared Calamine, Yellow Wax, each, *three ounces;* Lard *a pound.*

Melt the Wax and Lard together, and, when upon cooling they begin to thicken, add the Calamine, and stir the mixture constantly until cool." *U. S.*

The *London College* orders of prepared calamine and wax, each, *seven ounces and a half,* and of olive oil *a pint* [Imperial measure]; the *Edinburgh, one part* of prepared calamine, and *five parts* of simple cerate (*Ceratum Cetacei*, U. S.).

This is the *Ceratum Zinci Carbonatis* of the former U. S. Pharmacopœia, and is an imitation of the cerate recommended by Turner. It is mildly astringent, and is used in excoriations and superficial ulcerations, produced by the chafing of the skin, irritating secretions, burns, or other causes. W.

CERATUM CANTHARIDIS.* *U. S.* EMPLASTRUM CANTHARIDIS. *Lond., Ed., Dub.* EMPLASTRUM EPISPASTICUM. *Cerate of Spanish Flies. Blistering Plaster.*

"Take of Spanish Flies, in very fine powder, *a pound;* Yellow Wax, Resin, each, *seven ounces;* Lard *ten ounces.* To the Wax, Resin, and Lard, previously melted together and strained, add the Spanish Flies, and, by means of a water-bath, keep the mixture in a fluid state for half an hour, stirring occasionally; then remove it from the bath, and stir it constantly until cool." *U. S.*

The *London College* orders of Spanish flies, in very fine powder, *a pound;* wax, suet, each, *seven ounces and a half;* resin *three ounces,* and lard *six ounces;* adds to the wax, suet, and lard, melted together, the resin previously melted; then removes from the fire, and a little before cooling, sprinkles in the flies, and mixes. The *Edinburgh College* orders *two ounces,* each, of flies, resin, yellow wax, and suet; the *Dublin, six ounces* of flies, and *four ounces,* each, of yellow wax, resin, and prepared lard.

This is the common *blistering plaster* of the shops. As it can be readily spread without the aid of heat, it is properly a cerate, and is therefore correctly named in the U. S. Pharmacopœia. Though essentially the same in character as prepared by the different processes, it varies somewhat in strength. The U. S., London, and Dublin preparations have the same proportion of flies, but are stronger than that of the Edinburgh College. One of the former, therefore, is preferable. Care has usually been considered requisite, in making the cerate, not to injure the flies by heat. It has, therefore, been recommended that they should not be added to the other ingredients, until immediately before these begin to stiffen after having been removed from the fire. But from the experiments of Mr. Donovan (*Dublin Med. Press,* Aug. 1840), and those of Professor Procter (*Am. Journ. of Pharm.,* xiii. 302, and xxiv. 296), it may be inferred that the vesicating principle of Spanish flies is not injured or dissipated by a heat under 300° F., and that an elevated temperature, instead of being hurtful, is positively advantageous in the preparation of the blistering cerate. The cantharidin is thus more thoroughly dissolved by the oleaginous matter, and consequently brought more efficiently into contact with the skin, than when retained in the interior of the tissue of the fly. Another advantage, stated by Donovan, is that the moisture which usually exists to a certain extent in all the ingredients of the cerate is thus dissipated, and the preparation is less apt to become mouldy, or otherwise to undergo decomposition. Instead, therefore, of waiting until the melted wax, resin, and lard begin to stiffen, it is better to add the powder before the vessel is removed from the fire. Mr. Donovan recommends that, as soon as the other ingredients are melted, the powdered flies should be added, and the mixture stirred until the heat is shown by a thermometer to have risen to 250°, when the vessel is to be removed from the fire, and the mixture stirred constantly until cool. At the heat mentioned, ebullition takes place in

* This is a different preparation from the London *Ceratum Cantharidis,* for an account of which see *Unguentum Cantharidis, Ed.*

consequence of the escape of the moisture contained in the materials. In the cerate thus prepared, the active matter has been dissolved by the lard, and the powder may be separated, if deemed advisable, by straining the mixture before it solidifies. Care should be taken that the temperature be not so high as to decompose the ingredients; and it would be better to keep it within 212° by means of a water-bath, than to incur any risk from its excess. Violent irritation and even vesication of the face of the operator are stated to have resulted from exposure to the vapours of the liquid, at a temperature of 250°. (*Pharm. Journ. and Trans.*, ii. 391.) From an experiment, however, of Prof. Procter, it appears that, though cantharides begin to volatilize slightly at 250°, and rapidly rise in vapour and sublime at from 402° to 412°, yet they are not decomposed unless by increasing the heat considerably above the last mentioned point. (*Am. Journ. of Pharm.*, xxiv. 296 and 298.) It is desirable that the flies should be very finely pulverized. Powdered euphorbium is said to be sometimes fraudulently substituted for a portion of the flies.

The cerate will always raise a blister in ordinary conditions of the system, if the flies are good, and not injured in the preparation. It should be spread on soft leather, though linen or even paper will answer the purpose when that is not to be had. An elegant mode of preparing it for use is to spread a piece of leather, of a proper size, first with adhesive plaster, and afterwards with the cerate, leaving a margin of the former uncovered, in order that it may adhere to the skin. Heat is not requisite, and should not be employed in spreading the cerate. Some sprinkle powdered flies upon the surface of the plaster, press them lightly with a roller, and then shake off the portion which has not adhered; but, if the flies originally employed were good, this addition is superfluous. Prof. Procter is in the habit of applying over the surface with a brush an ethereal tincture of cantharides, which leaves a thin coating of extract, and renders the preparation more certain.

Upon the application of the plaster, the skin should be moistened with warm vinegar or other liquid; and a good rule is to cover the surface of the plaster closely with very thin gauze or unsized paper, which prevents any of the cerate from adhering to the cuticle, and is thought by some to diminish its liability to occasion strangury. In the cases of adults, when the full action of the flies is desired, and the object is to produce a permanent effect, the application should be continued for twelve hours, and on the scalp for twenty-four hours. In very delicate persons, however, or those subject to strangury, or upon parts of a loose texture, or when the object is merely to produce a blister to be healed as quickly as possible, the plaster should remain no longer than is necessary for the production of full redness of the skin, which generally occurs in five or six hours, or even in a shorter time. It should then be removed, and followed by a bread and milk poultice, or some other emollient dressing, under which the cuticle rises, and a full blister is usually produced. By this management the patient will generally escape strangury, and the blister will very quickly heal after the discharge of the serum.* In young children, cantharides sometimes produce

* Dr. M. B. Smith, of Philadelphia, informed us that he had frequently employed uva ursi, as a preventive of strangury from blisters, and had never found it to fail. He gave a small wineglassful of the officinal decoction (see *Decoctum Uvæ Ursi*) every hour, commencing two hours after the application of the blister. Camphor is sometimes incorporated with the blistering cerate to prevent strangury, though with doubtful effect. A plan proposed by M. Vée is to spread over the surface of the plaster, when ready for delivery, by means of the finger, a saturated solution of camphor in ether. The ether evaporates, leaving a thin coating of camphor uniformly diffused. (*Journ. de Pharm.*, 3e *sér.*, viii. 68.) The late Dr. Joseph Hartshorne, of Philadelphia, was in the habit, in cases where he apprehended strangury, of directing four grains of opium and twenty of camphor to be mixed with the cerate of a blister of large size, and experienced the happiest effects from the addition.

alarming and even fatal ulceration, if too long applied. From two to four hours are usually sufficient for any desirable purpose. When the head, or other very hairy part is to be blistered, an interval of ten or twelve hours should, if possible, be allowed between the shaving of the part and the application of the plaster; so that the abrasions may heal, and some impediment be offered to the absorption of the active principles of the flies. After the blister has been formed, it should be opened at the most depending parts, and, the cuticle being allowed to remain, should be dressed with simple cerate; but, if it be desirable to maintain the discharge for a short time, resin cerate should be used, and the cuticle removed, if it can be done without inconvenience. When it is wished that the blistered surface should heal as soon as possible, and with the least inconvenience to the patient, Dr. Maclagan recommends a dressing of cotton wadding; an emollient poultice being first applied for two hours after the removal of the blistering cerate, the cuticle then cut, and the surface afterwards covered with the cotton, with its raw surface next the skin. Should the dressing become soaked with the serous discharge, so much of the cotton may be removed as can be done without disturbing the cuticle, and a new batch applied. The cotton is to be allowed to remain until the old cuticle spontaneously separates. The effects of an issue may be obtained by employing savine ointment, or the ointment of Spanish flies, as a dressing. If much inflammation take place in the blistered surface, it may be relieved by emollient poultices, or weak lead-water. Where there is an obstinate indisposition to heal, we have found nothing so effectual as the cerate of subacetate of lead, mixed with an equal weight of simple cerate. When deep and extensive ulceration occurs in consequence of general debility, bark or sulphate of quinia should be used, with nutritious aliment.

Various preparations of cantharides have been proposed and employed as substitutes for the cerate. They consist for the most part of cantharidin, more or less pure, either dissolved in olive oil and applied to the skin by means of a piece of paper saturated with it, or incorporated with wax and spread in a very thin layer upon fine waxed cloth, silk, or paper, constituting the *blistering cloth*, *blistering paper*, *vesicating taffetas*, &c., of the shops. The advantages of these preparations are that they occupy less space, are more portable, and, being very pliable, are more easily adapted to irregularities of the surface. Absolutely pure cantharidin is expensive and not requisite; as extracts of cantharides, made with ether, alcohol, or boiling water, will answer every purpose. Henry and Guibourt give the following formula. Digest powdered cantharides in sulphuric ether, distil off the ether, evaporate the residue by means of a salt-water bath until ebullition ceases, melt the oily mass which remains with twice its weight of wax, and spread the mixture upon waxed cloth. The *waxed cloth* may be prepared by spreading upon linen or muslin a mixture composed of 8 parts of white wax, 4 of olive oil, and 1 of turpentine, melted together. An extract of cantharides, of a buttery consistence, said to act very efficiently when applied by means of paper greased with it, is prepared by digesting 4 parts of flies with 1 part of strong acetic acid and 16 of alcohol, straining, filtering, and evaporating at a moderate heat. A preparation which has received the favourable report of a committee of the Society of Pharmacy, at Paris, is the following, proposed by M. Dubuison. Four parts of a hydro-alcoholic extract of the flies made by maceration, is mixed with an aqueous solution of one part of pure gelatin, so as to obtain a solution of suitable consistence, which is then applied upon a piece of extended waxed cloth, care being taken that the brush should always have the same direction. When the first layer has dried, a second, and a third are to be applied in the same manner. The gelatin renders the cloth more adhesive and less deliquescent. The hydro-alcoholic extract is preferred to the alcoholic, because it contains less of the green oil, which does not readily mix with the

other ingredients. The committee, however, prefer the aqueous extract, as cheaper and more active. This taffeta has been tried, and found to raise blisters in four hours. (*Journ. de Pharm.*, 3e *sér.*, viii. 67.) A strong decoction of the flies in olive oil, applied by means of paper, would probably answer a similar purpose with these more elaborate preparations. But none of them is likely to supersede the officinal cerate. For very speedy vesication, an infusion of the flies in strong acetic acid is sometimes employed. (See *Acetum Cantharidis.*)

A preparation, called *cantharidal collodion*, has recently been introduced into use. It was originally proposed by M. Ilisch, of St. Petersburg, Russia, and is made in the following manner. Exhaust, by percolation, a pound of cantharides, with a mixture consisting of a pound of sulphuric ether and three ounces of acetic ether; and in two ounces of this liquid dissolve 25 grains of gun cotton. Professor Procter states that it has been found more advantageous to exhaust the flies with ether, distil off the ether, and mix the oily residue with collodion already prepared of the proper consistence. (*Am. Journ. of Pharm.*, xxiv. 303.) Mr. Charles S. Rand, in a communication to the *American Journal of Pharmacy* (xxii. 18), states that Ilisch's preparation made with double the proportion of ether vesicates equally well, and proposes the addition of about one per cent. of Venice turpentine, which he has found to prevent the disagreeable, and sometimes painful contraction of the preparation upon drying. The preparation may be kept indefinitely in a glass-stoppered bottle without change. It may be applied to the surface by means of a camel's hair brush, and, after the evaporation of the ether, which takes place in less than a minute, may be reapplied if the surface should not be well covered. It produces a blister in about the same time as the ordinary cerate, and has the advantage that it is applied with greater facility, is better adapted to cover uneven surfaces, and retains its place more certainly. According to Mr. Rand, if the evaporation of the ether be restrained by a piece of oiled silk immediately after its application, it will act much more speedily.

It is said that the flies, by ebullition with water, are deprived of their property of producing strangury, while their vesicating powers remain unaltered. (*Paris's Pharmacologia.*) Dr. Theophilus Beasly, of Philadelphia, was in the habit of employing a cerate made with cantharides prepared in this manner, and never knew it to produce strangury in more than two or three instances. (*Journ. of the Phil. Col. of Pharm.*, iv. 185.) In a letter addressed to one of the authors by Dr. James Couper, of Newcastle, Delaware, a similar method of preparing the flies is recommended as an expedient against strangury, both from his own experience and that of the late Dr. Groom, of Elkton, Maryland, from whom he derived his knowledge of the plan. Yet there can be no doubt that boiling water extracts cantharidin from the flies; and the cerate made as here recommended must be somewhat weaker in the blistering principle than the officinal.

Off. Prep. Emplastrum Picis cum Cantharide. W.

CERATUM CETACEI. *U. S.*, *Lond.* CERATUM SIMPLEX. *Ed.* UNGUENTUM CETACEI. *Dub.* *Spermaceti Cerate.*

"Take of Spermaceti *an ounce;* White Wax *three ounces;* Olive Oil *six fluidounces.* Melt together the Spermaceti and Wax; then add the Oil previously heated, and stir the mixture until cool." *U. S.*

The *London College* directs *two ounces* of spermaceti, *eight ounces* of white wax, and *a pint* [Imp. meas.] of olive oil; the *Edinburgh*, *six parts* of olive oil, *three parts* of white wax, and *one part* of spermaceti; the *Dublin*, *half a pound* of white wax, *a pound* of spermaceti, and *three pounds* of lard.

The direction to heat the oil before adding it to the other ingredients is peculiar to the U. S. and Edinburgh Pharmacopœias. If added cold, it is apt to produce an irregular congelation of the wax and spermaceti, and thus to render

the preparation lumpy. This cerate is employed as a dressing for blisters, excoriated surfaces, and wounds, and as the basis of more active preparations. When the ingredients are pure and sweet, it is perfectly free from irritating properties.

Off. Prep. Ceratum Cantharidis; Ceratum Calaminæ. W.

CERATUM HYDRARGYRI COMPOSITUM. *Lond. Compound Cerate of Mercury.*

"Take of Mercurial Ointment, Compound Soap Cerate, each, *six ounces;* Camphor *an ounce and a half.* Rub them together." *Lond.*

This cerate is used as a discutient application to indolent tumours. W.

CERATUM PLUMBI SUBACETATIS. *U. S.* CERATUM PLUMBI COMPOSITUM. *Lond. Cerate of Subacetate of Lead. Goulard's Cerate.*

"Take of Solution of Subacetate of Lead *two fluidounces and a half;* White Wax *four ounces;* Olive Oil *nine fluidounces;* Camphor *half a drachm.* Mix the Wax, previously melted, with eight fluidounces of the Oil; then remove the mixture from the fire, and, when it begins to thicken, gradually pour in the Solution of Subacetate of Lead, stirring constantly with a wooden spatula till it becomes cool. Lastly, add the Camphor dissolved in the remainder of the Oil, and mix." *U. S.*

The *London College* takes *six fluidounces* of the solution of subacetate of lead, *eight ounces* of wax, *a pint* [Imperial measure] of olive oil, and *a drachm* of camphor, and proceeds in the manner above directed.

This cerate becomes so speedily rancid that but little should be prepared at once, when the demand is not great. It received the name by which it is commonly known from M. Goulard, by whom it was employed and recommended. It is used to dry up excoriations, to relieve the inflammation of burns, scalds, and chilblains, and to remove cutaneous eruptions. We have found it more effectual than any other application to blistered surfaces indisposed to heal; and, on the recommendation of the late Dr. Parrish, have used it in the following combination with advantage in various cutaneous eruptions of a local character. Take of cerate of subacetate of lead, simple cerate, each, *half an ounce;* calomel, powdered opium, each, *a drachm;* mix them. The same preparation, without the opium, was a favourite remedy with the late Dr. Wistar in similar complaints. W.

CERATUM RESINÆ. *U. S., Lond.* UNGUENTUM RESINOSUM. *Ed.* UNGUENTUM RESINÆ. *Dub. Resin Cerate. Basilicon Ointment.*

"Take of Resin *five ounces;* Lard *eight ounces;* Yellow Wax *two ounces.* Melt them together, strain through linen, and stir them constantly until cool." *U. S.*

The proportions directed by the *Edinburgh College* are the same as the above. The *London College* orders of resin and wax, each *fifteen ounces,* and of olive oil *a pint* [Imperial measure]. The resin and wax are melted together over a slow fire, the oil then added, and the mixture while hot strained through linen. By the *Dublin* process *half a pound* [avoirdupois] of resin, in coarse powder, *four ounces* [avoird.] of yellow wax, and *a pound* [avoird.] of prepared lard, are melted, strained while hot through flannel, and stirred constantly till they concrete.

The straining is directed in consequence of the impurities which resin often contains. Resin cerate, commonly called *basilicon ointment,* is much used as a gently stimulant application to blistered surfaces, indolent ulcers, burns, scalds, and chilblains. We have found no application more effectual in disposing the ulcers which follow burns to heal.

Off. Prep. Ceratum Sabinæ; Linimentum Terebinthinæ; Unguentum Cantharidis; Unguentum Æruginis. W.

CERATUM RESINÆ COMPOSITUM. *U. S.* *Compound Resin Cerate.*

"Take of Resin, Suet, Yellow Wax, each, *a pound;* Turpentine *half a pound;* Flaxseed Oil *half a pint.* Melt them together, strain through linen, and stir them constantly until cool." *U. S.*

This is somewhat more stimulating than the preceding, but is applicable to similar purposes, particularly to the treatment of indolent ulcers. Under the name of *Deshler's salve*, it is popularly employed in some parts of the United States. It should be kept well protected from the air, in consequence of its liability when exposed to acquire a tough consistence. W.

CERATUM SABINÆ. *U. S.*, *Ed.* Unguentum Sabinæ. *Lond.*, *Dub.* *Savine Cerate.*

"Take of Savine, in powder, *two ounces;* Resin Cerate *a pound.* Mix the Savine with the Cerate previously softened." *U. S.*

The *London College* orders *half a pound* of fresh savine, bruised, to be mixed with *three ounces* of white wax and *a pound* of lard previously melted together, and the whole to be strained through linen. The *Edinburgh College* directs the same ingredients, in the same proportions, to be boiled together till the leaves become friable, and then strained. The *Dublin College* rubs intimately together *a drachm* of savine, in fine powder, and *seven drachms* of ointment of white wax.

As the savine used in this country is generally brought from Europe in the dried state, we are compelled to resort to the mode of preparing the cerate directed in the U. S. Pharmacopœia. Nor have we found the preparation thus made to be "intolerably acrid and almost caustic," as Dr. Duncan describes it. On the contrary, it answers very well the purpose for which it is used, that of maintaining the discharge from blistered surfaces. A cerate prepared in the same manner from the leaves of the red cedar (*Juniperus Virginiana*) is sometimes substituted for that of savine, but is less efficient.

Prepared according to the processes of the *London and Edinburgh* Colleges, savine cerate has a fine deep-green colour, and the odour of the leaves. It should be kept in closely covered vessels.

Savine cerate is preferable to the ointment of Spanish flies as a dressing for perpetual blisters, from the circumstance that it has no tendency to produce strangury. The white coating which forms during its use upon the blistered surface should be occasionally removed, as it prevents the contact of the cerate. It is sometimes applied to seton cords, with the view of increasing the discharge. W.

CERATUM SAPONIS. *U. S.* Ceratum Saponis Compositum. *Lond.* *Soap Cerate.*

"Take of Solution of Subacetate of Lead *two pints;* Soap *six ounces;* White Wax *ten ounces;* Olive Oil *a pint.* Boil the Solution of Subacetate of Lead with the Soap, over a slow fire, to the consistence of honey; then transfer to a water-bath, and evaporate until all the moisture is dissipated; lastly add the Wax previously melted with the Oil, and mix." *U. S.*

"Take of Soap *ten ounces;* Wax *twelve ounces and a half;* Oxide of Lead [litharge], in powder, *fifteen ounces;* Olive Oil *a pint* [Imperial measure]; Vinegar *a gallon* [Imp. meas.]. Boil the Vinegar with the Oxide of Lead over a slow fire, constantly stirring until they unite; then add the Soap, and again boil in a similar manner, until all the moisture is dissipated; lastly, with these mix the Wax previously dissolved in the Oil." *Lond.*

The present U. S. formula is that of Mr. Durand, given in the *American Journal of Pharmacy* (vol. viii. p. 27), and was substituted, in the U. S. Pharmacopœia of 1840, for the London formula, which had been adopted in the pre-

vious editions. It has the advantages of being more precise in the directions, more easy of execution, and more uniform in its results. It yields a perfectly white cerate, having the same properties as the London, and a finer appearance. The solution of subacetate of lead, which in the U. S. process is taken already prepared, results, in the London, from the action of the vinegar upon the litharge. In both processes, the subacetate of lead is decomposed by the soap, the soda of which unites with the acetic acid, and the oleaginous acids with the oxide of lead, in the same manner as in the formation of Emplastrum Plumbi. The wax and oil subsequently added merely serve to give due consistence to the preparation. Soap cerate is thought to be cooling and sedative; and is sometimes used in scrofulous swellings and other instances of chronic external inflammation. It was formerly employed by Mr. Pott as a dressing for fractured limbs; but answers no other purpose in these cases than to yield mechanical support.

Off. Prep. Ceratum Hydrargyri Compositum. W.

CERATUM SIMPLEX. *U. S.* Ceratum. *Lond. Simple Cerate.*

"Take of Lard *eight ounces;* White Wax *four ounces.* Melt them together, and stir them constantly until cool." *U. S.*

The *London College* directs that *a pint* [Imperial measure] of olive oil be mixed with *twenty ounces* of wax previously melted.

We prefer the U. S. formula. Lard is preferable to olive oil, as it may always be had perfectly sweet, and is the mildest application which can be made to irritated surfaces. In the preparation of this cerate, peculiar care should be taken that the oleaginous ingredient be entirely free from rancidity, and that the heat employed be not sufficient to produce the slightest decomposition; for the value of the preparation depends on its perfect blandness. To avoid change, it should be put up in small jars, and covered closely with tin foil so as to exclude the air. It is used for dressing blisters, wounds, &c., in all cases in which the object is to prevent the contact of air and preserve the moisture of the part, and at the same time to avoid all irritation. It is sometimes improperly employed as the vehicle of substances to be applied by inunction. For this purpose lard should be used in winter, and simple ointment in summer; the cerate having too firm a consistence. W.

CERATUM ZINCI CARBONATIS. *U. S. Cerate of Carbonate of Zinc.*

"Take of Precipitated Carbonate of Zinc *two drachms;* Simple Ointment *ten drachms.* Mix them." *U. S.*

This cerate was intended as a substitute for the former Ceratum Zinci Carbonatis of the U. S. Pharmacopœia, now Ceratum Calaminæ, as being more to be depended on in consequence of the frequent falsification of calamine. For its uses, see *Ceratum Calaminæ.* W.

CONFECTIONES. *U. S., Lond.*

Confections.

Confections. *Dub.* Conserves and Electuaries. *Ed.*

Under the general title of Confections, the Pharmacopœias of the United States, London, and Dublin, include all those preparations having the form of a soft solid, in which one or more medicinal substances are incorporated with saccharine matter, with a view either to their preservation or more convenient administration. The Edinburgh College retains the old division into Conserves and Electuaries; and, as there is some ground for the distinction, we shall make

a few general remarks upon each division, before proceeding to the consideration of the individual preparations.

Conserves consist of recent vegetable substances and refined sugar beat into a uniform mass. By means of the sugar, the vegetable matter is enabled to resist for some time the decomposition to which it would otherwise be exposed in the undried state, and the properties of the recent plant are thus retained to a certain extent unaltered. But, as active medicines even thus treated undergo some change, and those which lose their virtues by desiccation cannot be long preserved, the few conserves now retained are intended rather as convenient vehicles of other substances than for separate exhibition. The sugar used in their preparation should be reduced to a fine powder by pounding and sifting, as otherwise it will not mix uniformly with the other ingredient.

Electuaries are mixtures consisting of medicinal substances, especially dry powders, combined with syrup or honey, in order to render them less unpleasant to the taste, and more convenient for internal use. They are usually prepared extemporaneously; and it is only when their complex nature renders it convenient to keep them ready made in the shops, or some peculiarity in the mode of mixing the ingredients requires attention, that they become proper objects for pharmaceutic direction. Their consistence should not be so soft, on the one hand, as to allow the ingredients to separate, nor so firm, on the other, as to prevent them from being swallowed without mastication. Different substances require different proportions of syrup. Light vegetable powders usually require twice their weight, gum-resins two-thirds of their weight, resins somewhat less, mineral substances about half their weight, and deliquescent salts not more than one-tenth. Should the electuary be found, after having been kept for a short time, to swell up and emit gas, it should be beat over again in a mortar, so that any portion of the sugar which may have crystallized may be again accurately incorporated with the other ingredients. Should it, on the contrary, become dry and hard from the mutual reaction of its constituents, more syrup should be added, so as to give it the requisite consistence. If the dryness result from the mere evaporation of the aqueous part, water should be added instead of syrup, and the same remark is applicable to the conserves. To prevent the hardening of electuaries, the French writers recommend the use of syrup prepared from brown sugar, which is less apt to crystallize than that made from the refined. Molasses would answer the same purpose; but its taste might be considered objectionable. Some persons employ honey, but this is not always acceptable to the stomach. W.

CONFECTIO AMYGDALÆ. *Lond.* Conserva Amygdalarum. *Ed.* *Almond Confection.*

"Take of [sweet] Almonds *eight ounces;* Gum Arabic, in powder, *an ounce;* Sugar *four ounces.* Having macerated the Almonds in cold water, and deprived them of their external coat, bruise them, and rub them through a fine metallic sieve; then, having added the other ingredients, beat altogether till they are thoroughly incorporated. The confection may be kept longer, if the Almonds, previously denuded, dried, and rubbed to a very fine powder, should be mixed with the gum Arabic and sugar separately powdered, and the mixed powder preserved in a stopped bottle." *Lond.*

The directions of the *Edinburgh College* are essentially the same as the above, except that this College does not admit the alternative of having the ingredients separately rubbed, and afterwards mixed.

This preparation is intended to afford a speedy method of preparing the almond mixture, which, when made immediately from the Almonds, requires much time, and which cannot be kept ready made in the shops. But, from its liability to

be injured by keeping, it was omitted from our Pharmacopœia, which directs the almond mixture to be made immediately from the ingredients.

Mistura Amygdalæ. W.

CONFECTIO AROMATICA. *U. S.*, *Lond.*, *Dub.* Electuarium Aromaticum. *Ed.* *Aromatic Confection.*

"Take of Aromatic Powder *five ounces and a half;* Saffron, in powder, *half an ounce;* Syrup of Orange Peel *six ounces;* Clarified Honey *two ounces.* Rub the Aromatic Powder with the Saffron; then add the Syrup and Honey, and beat the whole together until thoroughly mixed." *U. S.*

"Take of Cinnamon, Nutmegs, each, *two ounces;* Cloves *an ounce;* Cardamom *half an ounce;* Saffron *two ounces;* Prepared Chalk *sixteen ounces;* Sugar *two pounds;* Distilled Water *a sufficient quantity.* Rub the dry ingredients together to a very fine powder, and keep them in a closed vessel. But when the confection is to be used, to every ounce of the powder add *two fluidrachms* of the Water, and mix all together until incorporated." *Lond.*

The *Dublin College* rubs *five ounces* [avoirdupois] of aromatic powder with *half an ounce* of saffron in powder; then adds *five fluidounces* of simple syrup, and *two ounces* [avoirdupois] of clarified honey, and beats them together till thoroughly mixed; and lastly adds *half a fluidrachm* of oil of cloves. The *Edinburgh College* directs *one part* of its aromatic powder, and *two parts* of syrup of orange peel to be mixed, and triturated into a uniform pulp.

The preparation of the U. S. Pharmacopœia contains cinnamon, ginger, cardamom, and nutmeg, without prepared chalk, which appears to us to be an unnecessary if not improper ingredient; as it is not always indicated in cases which call for the use of the confection, and may be added extemporaneously when required. The aromatic confection affords a convenient method of administering the spices which enter into its composition, and an agreeable vehicle for other medicines. It is given in debilitated states of the stomach, alone or as an adjuvant to other substances. The dose is from ten to sixty grains.

Off. Prep. Pilulæ Digitalis et Scillæ. W.

CONFECTIO AURANTII CORTICIS. *U. S.* Confectio Aurantii. *Lond.* Conserva Aurantii. *Ed.* *Confection of Orange Peel.*

"Take of Orange Peel, recently separated from the fruit by grating, *a pound;* Sugar [refined] *three pounds.* Beat the Orange Peel with the Sugar gradually added, till they are thoroughly mixed." *U. S.*

The directions of the *London* and *Edinburgh Colleges* correspond with the above. The rind of the bitter orange is intended by these Colleges, that either of the bitter or sweet by the U. S. Pharmacopœia. By the London process, the beating is performed in a stone mortar with a wooden pestle.

This confection is sometimes used as a grateful aromatic vehicle or adjunct of tonic and purgative powders. W.

CONFECTIO CASSIÆ. *Lond.* *Confection of Cassia.*

"Take of Prepared Cassia *half a pound;* Manna *two ounces;* Prepared Tamarinds *an ounce;* Syrup of Roses *eight fluidounces.* Bruise the Manna, and dissolve it in the Syrup; then mix in the Cassia and Tamarinds, and evaporate to the proper consistence." *Lond.*

The confection of cassia is slightly laxative; but is seldom if ever prepared in this country, and might very properly be expunged from the catalogue of preparations, as it is both feeble and expensive. W.

CONFECTIO CATECHU COMPOSITA. *Dub.* Electuarium Catechu. *Ed.* *Compound Confection of Catechu.*

"Take of Compound Powder of Catechu *five ounces* [avoirdupois]; Simple

Syrup *five fluidounces.* Add the Syrup gradually to the Powder, and mix them well together." *Dub.*

"Take of Catechu and Kino, of each, *four ounces;* Cinnamon and Nutmeg, of each, *one ounce;* Opium, diffused in a little Sherry, *one drachm and a half;* Syrup of Red Roses, reduced to the consistence of honey, *one pint and a half* [Imperial measure]. Pulverize the solids, mix the opium and syrup, then the powders, and beat them thoroughly into a uniform mass." *Ed.*

The Edinburgh Confection is aromatic and astringent, containing one grain of opium in about two hundred grains of the mass; and may be advantageously given in diarrhœa and chronic dysentery, in the dose of half a drachm or a drachm more or less frequently repeated. It may be taken in the form of bolus, or diffused in water. The Dublin Confection contains no opium, but is similar in other respects. W.

CONFECTIO OPII. *U. S., Lond.* Electuarium Opii. *Ed. Confection of Opium.*

"Take of Opium, in powder, *four drachms and a half;* Aromatic Powder *six ounces;* Clarified Honey *fourteen ounces.* Rub the Opium with the Aromatic Powder, then add the Honey, and beat the whole together until thoroughly mixed." *U. S.*

"Take of Opium, in powder, *six drachms;* Long Pepper *an ounce;* Ginger, in powder, *two ounces;* Caraway *three ounces;* Tragacanth, in powder, *two drachms;* Syrup *sixteen fluidounces* [Imperial measure]. Rub the dry ingredients together to a very fine powder, and keep it in a covered vessel. But when the Confection is to be used, add the powder gradually to the Syrup previously heated, and mix." *Lond.*

"Take of Aromatic Powder *six ounces;* Senega, in fine powder, *three ounces;* Opium, diffused in a little Sherry, *half an ounce;* Syrup of Ginger *a pound.* Mix them together, and beat them into an electuary." *Ed.*

This confection was intended as a substitute for those exceedingly complex and unscientific preparations which were formerly known by the names of *theriaca* and *mithridate,* and which have been expelled from modern pharmacy. The *seneka,* directed in the last edition of the Edinburgh Pharmacopœia, was probably put inadvertently for *serpentaria,* directed in the old Latin edition. The former medicine has no property which adapts it to this position. The preparation is a combination of opium with spices, which render it more stimulant, and more grateful to a debilitated stomach. It is given in atonic gout, flatulent colic, diarrhœa unattended with inflammation, and in various other diseases requiring the use of a stimulant narcotic. Added to Peruvian bark or sulphate of quinia, it increases considerably the efficacy of this remedy in obstinate cases of intermittent fever. One grain of opium is contained in about thirty-six grains of the U. S. and London confections, and in forty-three of the Edinburgh. W.

CONFECTIO PIPERIS. *Lond.* Confectio Piperis Nigri. *Dub.* Electuarium Piperis. *Ed. Confection of Black Pepper.*

"Take of Black Pepper, Elecampane, each, *a pound;* Fennel [seeds] *three pounds;* Honey, Sugar [refined], each, *two pounds.* Rub the dry ingredients together into a very fine powder, and keep them in a covered vessel. But whenever the confection is to be used, add the powder gradually to the Honey, and beat them until thoroughly incorporated." *Lond.*

"Take of Black Pepper, Liquorice Root in powder, each, *a pound;* Fennel *three pounds;* Honey, White Sugar, each, *two pounds.* Triturate the solids together into a very fine powder; add the Honey; and beat the whole into a uniform mass." *Ed.*

"Take of Black Pepper, in fine powder, Liquorice Root, in powder, each, *half an ounce* [avoirdupois]; Refined Sugar *one ounce* [avoird.]; Oil of Fennel *half a fluidrachm;* Clarified Honey *two ounces* [avoird.]. Rub the dry substances together into a very fine powder, then add the Honey and Oil, and beat them into a uniform mass." *Dub.*

This preparation was intended as a substitute for *Ward's paste*, which acquired some reputation in Great Britain as a remedy in piles and ulcers of the rectum. To do good, it must be continued, according to Mr. Brodie, for two, three, or four months. The dose is from one to two drachms repeated two or three times a day. Its stimulating properties render it inapplicable to cases attended with much inflammation. W.

CONFECTIO ROSÆ. *U. S., Lond., Dub.* CONSERVA ROSÆ. *Ed. Confection of Roses. Conserve of Roses.*

"Take of Red Roses, in powder, *four ounces;* Sugar [refined], in powder, *thirty ounces;* Clarified Honey *six ounces;* Rose Water *eight fluidounces.* Rub the Roses with the Rose Water heated to 150°; then gradually add the Sugar and Honey, and beat the whole together until thoroughly mixed." *U. S.*

"Take of fresh Red Roses *a pound;* Sugar [refined] *three pounds.* Beat the Roses in a marble mortar; then add the Sugar, and beat again until they are incorporated." *Lond.*

The *Edinburgh College* directs the petals to be beaten into a pulp with the gradual addition of twice their weight of white sugar. The *Dublin College*, using the avoirdupois weights, macerates *an ounce* of the dried roses in *two fluidounces* of rose water for two hours, adds gradually *eight ounces* of refined sugar, and beats them into a uniform mass; or, it prepares the confection in the same manner as the London College, using three parts of petals to eight of sugar.

In the London process, the unblown petals only are used, and these should be deprived of their claws; in other words, the rose buds should be cut off a short distance above their base, and the lower portion rejected. In the last two editions of the U. S. Pharmacopœia, dried roses have been substituted for the fresh, as the latter are not brought to our market. The process is very similar to that of the French Codex. We have been informed, however, that much of the confection of roses made in Philadelphia is prepared from the fresh petals of the hundred-leaved rose and others, by beating them into a pulp with sugar as in the London process. An excuse for this deviation from the officinal formula is, that the confection thus made has greater adhesiveness than the officinal, and is therefore better fitted for the formation of pills.

This confection is slightly astringent, but is almost exclusively used as a vehicle of other medicines, or to impart consistence to the pilular mass. The Edinburgh College employs it in most of its officinal pills.

Off. Prep. Pilulæ Hydrargyri. W.

CONFECTIO ROSÆ CANINÆ. *Lond.* CONSERVA ROSÆ FRUCTÛS. *Ed. Confection of Dog Rose.*

"Take of Dog Rose, enucleated, *a pound;* Sugar [refined], in powder, *twenty ounces.* Rub the Rose with the Sugar gradually added, until they are incorporated." *Lond.*

"Take any convenient quantity of hips, carefully deprived of their carpels, beat them to a fine pulp, adding gradually thrice their weight of white Sugar." *Ed.*

This preparation is acidulous and refrigerant, and is used in Europe for forming more active medicines into pills and electuaries. W.

CONFECTIO RUTÆ. *Lond. Confection of Rue.*

"Take of Rue, recently powdered, Caraway, Laurel [fruit], each, *an ounce and*

a half; Prepared Sagapenum *half an ounce;* Black Pepper *two drachms;* Honey [clarified] *sixteen ounces.* Rub the dry ingredients together to a very fine powder; then, the Sagapenum having been liquefied over a slow fire with the Water and Honey, gradually add the powder, and mix all together." *Lond.*

The confection of rue is antispasmodic, and in Great Britain is employed in the form of enema in hysterical complaints and flatulent colic; but in this country it is not used. From a scruple to a drachm may be administered, diffused in half a pint of warm mucilaginous fluid. W.

CONFECTIO SCAMMONII. *Lond., Dub. Confection of Scammony.*

"Take of Scammony *an ounce and a half;* Cloves, bruised, Ginger, in powder, each, *six drachms;* Oil of Caraway *half a fluidrachm;* Syrup of Roses *a sufficient quantity.* Rub the dry ingredients into a very fine powder, and keep them in a closed vessel; then, when the Confection is to be used, pour in the Syrup, and again rub them; finally, add the Oil of Caraway, and mix them all." *Lond.*

The *Dublin College,* employing avoirdupois weights, beats *three ounces* of powdered scammony, and *an ounce and a half* of finely powdered ginger, with *three fluidounces* of simple syrup and *an ounce and a half* of clarified honey; then adds *half a fluidrachm,* each, of oil of cloves and oil of caraway, and mixes all together.

This confection is actively cathartic in the dose of half a drachm or a drachm; but is very little used. The proportion of scammony in the London preparation is uncertain, from the indefinite quantity of syrup employed. W.

CONFECTIO SENNÆ. *U.S., Lond., Dub.* ELECTUARIUM SENNÆ. *Ed. Confection of Senna. Lenitive Electuary.*

"Take of Senna *eight ounces;* Coriander [seed] *four ounces;* Liquorice Root, bruised, *three ounces;* Figs *a pound;* Pulp of Prunes, Pulp of Tamarinds, Pulp of Purging Cassia, each, *half a pound;* Sugar [refined] *two pounds and a half;* Water *four pints.* Rub the Senna and Coriander together, and separate ten ounces of the powder with a sieve. Boil the residue with the Liquorice Root and Figs, in the Water, to one-half; then press out the liquor and strain. Evaporate the strained liquor, by means of a water-bath, to a pint and a half; then add the Sugar and form a syrup. Lastly, rub the Pulps with the syrup gradually added, and, having thrown in the sifted powder, beat all together until thoroughly mixed." *U. S.*

The *London* process corresponds with the above. The *Edinburgh College* directs *a pound* of the pulp of prunes, and omits the pulps of tamarinds and cassia fistula; but otherwise proceeds in the same manner. The *Dublin College,* using avoirdupois weights, takes of finely powdered senna *two ounces,* finely powdered coriander *an ounce,* oil of caraway *half a fluidrachm,* pulp of prunes *five ounces,* pulp of tamarinds *two ounces,* brown sugar *eight ounces,* and water *two fluidounces;* dissolves the sugar in the water, and beats the pulps to a uniform consistence; then, having stirred in the powders and oil, mixes all well together, and heats the mass thoroughly in a water-bath for ten minutes.

The confection of senna, when properly made, is an elegant preparation. Directions may be found under *Pulpæ* for preparing the several pulps referred to in the U. S. formula; but the apothecary will find it most convenient to prepare them in connexion with this process; and, by following the directions here given, he will approximate very closely to the result aimed at in the officinal directions. Take *sixteen ounces* of cassia fistula, *ten ounces* of tamarinds, and *seven ounces* of prunes; bruise and slice them; digest with sufficient boiling water thoroughly to soften the pulps; remove as far as convenient the fragments of the cassia pods, and the seeds and fibres of the prunes and tamarinds; and

then separate the pulp by rubbing through a hair sieve. The crude substances will, in the quantities mentioned, each yield on the average half a pound of pulp. It is common to omit the cassia pulp in the preparation of the confection, as the pods are not always to be found in the market. But as this is next to senna the most active ingredient, the omission is to be regretted; and there is no doubt that a steady demand for the fruit would be met by an abundant supply from the West Indies.

This is one of our best and most pleasant laxatives, being admirably adapted to cases of habitual costiveness, especially in pregnant women and persons affected with piles. It is also very useful in the constipation which is apt to attend convalescence from fevers and other acute diseases. The mean dose is two drachms, to be taken at bedtime. W.

CONFECTIO SULPHURIS. *Dub.* *Confection of Sulphur.*

"Take of Sublimed Sulphur *two ounces;* Bitartrate of Potassa *one ounce;* Clarified Honey, by weight, *one ounce;* Syrup of Ginger, Syrup of Saffron, of each, *half a fluidounce.* Triturate all the ingredients in a mortar, until they are intimately mixed." *Dub.* The weights here employed are avoirdupois.

This is merely a mode of administering the two laxatives sulphur and bitartrate of potassa; and the relative proportion of the latter is so small that it can have little effect. The dose may be from two drachms to half an ounce or more. W.

CONFECTIO TEREBINTHINÆ. *Dub.* *Confection of Turpentine.*

"Take of Oil of Turpentine *one fluidounce;* Liquorice Root, in powder, *one ounce;* Clarified Honey, by weight, *two ounces.* Rub the Oil of Turpentine with the Liquorice Powder, then add the Honey, and beat them all together into a uniform consistence." *Dub.* The weights employed are avoirdupois.

Confections might be multiplied indefinitely upon the principle which appears to have been adopted here, that, namely, of giving a convenient formula for the administration of medicines. The effects of this confection are those only of the oil of turpentine. The dose may be from a scruple to a drachm. W.

CUPRUM.

Preparations of Copper.

CUPRI SUBACETAS PRÆPARATUM. *Dub.* *Prepared Subacetate of Copper.*

"Take of Subacetate of Copper *a convenient quantity.* Reduce it to powder by careful trituration in a porcelain mortar, and separate the finer parts for use by means of a sieve." *Dub.*

By the process of the former Dublin Pharmacopœia, in which levigation and elutriation were employed, a chemical change was effected, which was not originally contemplated, the object being merely to reduce verdigris to the state of very fine powder. This object is accomplished by the present process. The preparation is used only as an escharotic and stimulant application to unhealthy ulcers and obstinate cutaneous eruptions.

Off. Prep. Unguentum Cupri Subacetatis. W.

CUPRUM AMMONIATUM. *U. S., Ed.* CUPRI AMMONIO-SULPHAS. *Lond., Dub.* *Ammoniated Copper.*

"Take of Sulphate of Copper *half an ounce;* Carbonate of Ammonia *six drachms.* Rub them together in a glass mortar till the effervescence ceases; then wrap the Ammoniated Copper in bibulous paper, and dry it with a gentle heat. Let it be kept in a well-stopped glass bottle." *U. S.*

The processes of the British Colleges are essentially the same as the above, the ingredients, proportions, and general mode of operating being identical. The *London College* orders that the salt be dried in the air, and omits the direction as to the mode of keeping it; the *Edinburgh* directs that the product should be first dried in folds of blotting paper, and afterwards by exposure for a short time to the air; and the *Dublin* orders the ingredients to be triturated in a porcelain mortar, and the drying to be effected in bibulous paper on a porous brick.

When the two salts above mentioned are rubbed together, a reaction takes place between them attended with the extrication of the water of crystallization of the sulphate of copper, which renders the mass moist, and with the simultaneous escape of carbonic acid gas from the carbonate (sesquicarbonate) of ammonia, which occasions an effervescence. The colour is at the same time altered, passing from the light blue of the powdered sulphate of copper to a beautiful deep azure. The nature of the chemical changes which take place is not precisely known. One of the views which have been taken is, that the blue vitriol parts with a portion of its acid to the ammonia of the carbonate, thus forming a subsulphate of copper and sulphate of ammonia, which are either mixed together, or chemically united in the form of a double salt, the sulphate of copper and ammonia. According to Phillips, the sulphuric acid of the sulphate of copper unites with the ammonia of a portion of the sesquicarbonate of ammonia; while the carbonic acid of the decomposed sesquicarbonate partly escapes, and partly combines with the oxide of copper; so that the resulting preparation consists of sulphate of ammonia, carbonate of copper, and undecomposed sesquicarbonate of ammonia. It is highly probable that Cuprum Ammoniatum, independently of the excess of sesquicarbonate of ammonia which it may contain, is identical with the crystallized salt obtained by dropping a solution of pure ammonia into a solution of sulphate of copper till the subsalt first thrown down is dissolved, then concentrating, and precipitating by alcohol. Now, from the analysis of this salt by Berzelius, it appears to contain one equivalent of sulphuric acid, one of oxide of copper, two of ammonia, and one of water, which may be supposed to be combined in the form of a double salt—the *cupro-sulphate of ammonia*—consisting of one equiv. of sulphate of ammonia, one of cuprate of ammonia, in which the oxide of copper acts the part of an acid, and one of water of crystallization ($NH_3,SO_3+NH_3,CuO+HO$). But as half an ounce of sulphate of copper would require for such a result somewhat less than the same weight of sesquicarbonate of ammonia, there must be a considerable excess of the latter salt, unless dissipated in the drying process. In the uncertainty which exists as to the precise nature of the preparation, the name of *ammoniated copper* appears to be as appropriate for a pharmaceutical title as any that could be adopted.

This salt has a beautiful deep azure-blue colour, a strong ammoniacal odour, and a styptic, metallic taste. It is soluble in water, and the solution has an alkaline reaction on vegetable colours; but, unless there be excess of sesquicarbonate of ammonia, the solution deposits subsulphate of copper if much diluted. When exposed to the air it parts with ammonia, and is said to be ultimately converted into sulphate of ammonia and carbonate of copper. This change is apt to occur to a greater or less extent while it is drying. It should not, therefore, be prepared in large quantities at a time, and should be kept in well-closed bottles. By heat, the whole of it is dissipated, except the oxide of copper. Arsenious acid precipitates a green arsenite of copper from its solution. Potassa, soda, lime-water, and the acids are incompatible with it.

Medical Properties and Uses. Ammoniated copper is tonic, and is thought to exercise an influence over the nervous system which renders it antispasmodic. It has been much employed in epilepsy, in which it was recommended by Cullen.

There is good reason to believe that it has occasionally effected cures; but like all other remedies in that complaint it very frequently fails. It has also been used in chorea, hysteria, and worms; and by Swediaur as an injection in gonorrhœa and leucorrhœa. In over-doses it produces vomiting, and the poisonous effects which result from the other preparations of copper. (See *Cuprum.*) It is said, however, to be less apt to excite nausea. The dose is a quarter or half a grain, repeated twice a day, and gradually increased to four or five grains. It may be given in pill or solution. The medicine should not be very long continued without interruption; according to Cullen, not longer than a month.

Off. Prep. Cupri Ammoniati Solutio; Pilulæ Cupri Ammoniati. W.

CUPRI AMMONIATI SOLUTIO. *Ed.* LIQUOR CUPRI AMMONIO-SULPHATIS. *Lond.* *Solution of Ammoniated Copper.*

"Take of Ammonio-sulphate of Copper *a drachm;* Distilled Water *a pint* [Imperial measure]. Dissolve and filter." *Lond.*

The *Edinburgh* formula is the same as the *London.*

By the quantity of water employed in these processes, the ammoniated copper, unless it contain an excess of carbonate of ammonia, which it probably does when recently prepared, is said by Mr. Phillips to be decomposed, with a precipitation of one-half of the oxide of copper. According to the same author, a smaller portion of water dissolves it perfectly.

This solution is sometimes employed as a stimulant to foul and indolent ulcers, and, diluted with water, as an application to the cornea when affected with specks or opacity; but it is probably in no respect superior for these purposes to a solution of sulphate of copper, and scarcely deserves a place among the officinal preparations. W.

CUPRI SULPHAS. *Lond.* *Sulphate of Copper.*

"Take of Commercial Sulphate of Copper *four pounds;* Boiling Distilled Water *four pints* [Imperial measure]. Pour the Water upon the Sulphate, and apply heat, occasionally stirring until it is dissolved. Filter the solution while hot, and set it aside that crystals may form. Evaporate the decanted liquor, that it may again crystallize. Dry all the crystals." *Lond.*

This is merely a method of purifying commercial sulphate of copper. For the properties and uses of the purified salt the reader is referred to *Cupri Sulphas* in the first part of this work. The London College gives as tests of its purity, that it is [wholly] soluble in water, and that whatever ammonia throws down from the solution is redissolved by the ammonia in excess.

Off. Prep. Cupri Ammonio-sulphas. W.

DECOCTA.

Decoctions.

Decoctions are solutions of vegetable principles, obtained by boiling the substances containing these principles in water. Vegetables generally yield their soluble ingredients more readily and in larger proportion to water maintained at the point of ebullition, than to the same liquid at a lower temperature. Hence decoction is occasionally preferred to infusion as a mode of extracting the virtues of plants, when the call for the remedy is urgent, and the greatest possible activity in the preparation is desirable. The process should be conducted in a covered vessel, so as to confine the vapour over the surface of the liquid, and thus prevent the access of atmospheric air, which sometimes exerts an injurious agency upon the active principle. The boiling, moreover, should not, as a general rule, be long continued; as the ingredients of the vegetable are apt to react

on each other, and thus lose, to a greater or less extent, their original character. The substance submitted to decoction should if dry be either powdered or well bruised, if fresh should be sliced, so that it may present an extensive surface to the action of the solvent; and previous maceration for some time in water is occasionally useful by overcoming the cohesion of the vegetable fibre. Should the physician in his prescription not happen to direct this preliminary comminution, the apothecary should nevertheless not omit it.

All vegetable substances are not proper objects for decoction. In many the active principle is volatile at a boiling heat, in others it undergoes some change unfavourable to its activity, and in a third set is associated with inefficient or nauseous principles, which, though insoluble or but slightly soluble in cool water, are abundantly extracted by that liquid at the boiling temperature, and thus encumber, if they do not positively injure the preparation. In all these instances, infusion is preferable to decoction. Besides, by the latter process, more matter is often dissolved than the water can retain, so that upon cooling a precipitation takes place, and the liquid is rendered turbid. When the active principle is thus dissolved in excess, the decoction should always be strained while hot; so that the matter which separates on cooling, may be mixed again with the fluid by agitation at the time of administering the remedy.

In compound decoctions, the ingredients may be advantageously added at different periods of the process, according to the length of boiling requisite for extracting their virtues; and, should any one of them owe its activity to a volatile principle, the proper plan is, at the close of the process, to pour upon it the boiling decoction, and allow the liquor to cool in a covered vessel.

As a general rule, glass or earthenware vessels should be preferred; as those made of metal are sometimes corroded by the ingredients of the decoction, which thus becomes contaminated. Vessels of clean cast-iron or common tin, or of block tin, are preferable to those of copper, brass, or zinc; but iron pots should not be used when astringent vegetables are concerned.

Decoctions, from the mutual reaction of their constituents, as well as from the influence of the air, are apt to spoil in a short time. Hence they should be prepared only when wanted for use, and should not be kept, in warm weather, for a longer period than forty-eight hours. W.

DECOCTUM ALOES COMPOSITUM. *Lond.*, *Dub.* DECOCTUM ALOES. *Ed.* *Compound Decoction of Aloes.*

"Take of Extract of Liquorice *seven drachms;* Carbonate of Potassa *a drachm;* Extract of Aloes, Myrrh, in powder, Saffron, each, *a drachm and a half;* Distilled Water *a pint and a half* [Imperial measure]; Compound Tincture of Cardamom *seven fluidounces.* Boil the Liquorice, Carbonate, Aloes, Myrrh, and Saffron with the Water to a pint [Imp. meas.], and strain; then add the Tincture." *Lond.*

"Take of Socotrine or Hepatic Aloes, Powder of Myrrh, and Saffron, each, *one drachm;* Extract of Liquorice *half an ounce;* Carbonate of Potash *two scruples;* Compound Tincture of Cardamom *four fluidounces;* Water *sixteen fluidounces.* Mix the Aloes, Myrrh, Saffron, Liquorice, and Carbonate of Potash with the Water; boil down to *twelve* [*fluid*]*ounces;* filter, and add the Compound Tincture of Cardamom." *Ed.*

"Take of Hepatic Aloes, in powder, *a drachm and a half;* Myrrh, in powder, Saffron, chopped fine, of each, *one drachm;* Pure Carbonate of Potash *two scruples;* Extract of Liquorice *half an ounce;* Water *fourteen* [*fluid*]*ounces;* Compound Tincture of Cardamom *as much as is sufficient.* Rub the Aloes, Myrrh, and Carbonate of Potash together, then add the Saffron and Extract of Liquorice, and boil for ten minutes in a covered vessel; cool, strain through flannel, and add

of Compound Tincture of Cardamom as much as will make *sixteen fluidounces.*" *Dub.* The weights employed in this process are avoirdupois.

There is no essential difference between these processes.

The aloes, myrrh, and carbonate of potassa should be rubbed together before the addition of the other ingredients. The effect of the alkaline carbonate is, by combining with the resin of the myrrh, and the insoluble portion (apotheme of *Berzelius*) of the aloes, to render them more soluble in water; while the liquorice assists in the suspension of the portion not actually dissolved. The tincture of cardamom is useful not only by its cordial property, but also by preventing spontaneous decomposition.

Long boiling impairs the purgative property of aloes; and the same effect is thought to be produced, to a certain extent, by the alkalies, which certainly qualify its operation, and render it less apt to irritate the rectum. This decoction, therefore, is milder as a cathartic than aloes itself, and not so liable to produce or aggravate hemorrhoidal disease. At the same time it is more tonic and cordial from the presence of the myrrh, saffron, and cardamom, and derives antacid properties from the carbonate of potassa. It is given as a gentle cathartic, tonic, and emmenagogue; and is especially useful in dyspepsia, habitual constipation, and those complicated cases in which suppressed or retained menstruation is connected with enfeebled digestion and a languid state of bowels. The dose is from half a fluidounce to two fluidounces. The decoction should not be combined in prescription with acids, acidulous salts, or other saline bodies which are incompatible with the alkaline carbonate. W.

DECOCTUM CETRARIÆ. *U. S.*, *Lond.* DECOCTUM LICHENIS ISLANDICI. *Dub.* *Decoction of Iceland Moss.*

"Take of Iceland Moss *half an ounce;* Water *a pint and a half.* Boil down to a pint, and strain with compression." *U. S.*

The *London College* orders *five drachms* of the moss with *a pint and a half* of water to be boiled to a pint and strained; but, as the Imperial measure is used in the process, the proportion is in fact equivalent to about half an ounce to the apothecaries' pint. The *Dublin College* orders *an ounce* (avoirdupois) of the moss to be washed in cold water to purify it, then to be boiled for ten minutes in *a pint and a half* of water (Imp. meas), and strained while hot.

As the bitter principle is dissolved along with the starch of the moss, this decoction unites an unpleasant flavour to its demulcent properties; but the plan which has been proposed of first extracting the bitterness by maceration in water, or a very weak solution of an alkaline carbonate, and afterwards preparing the decoction, is inadmissible; as the peculiar virtues which distinguish the medicine from the ordinary demulcents are thus entirely lost. (See *Cetraria.*) A pint of the decoction may be taken in divided doses during the twenty-four hours. W.

DECOCTUM CHIMAPHILÆ. *U. S.*, *Lond.* DECOCTUM PYROLÆ. *Dub.* *Decoction of Pipsissewa.* *Decoction of Winter Green.*

"Take of Pipsissewa, bruised, *an ounce;* Water *a pint and a half.* Boil down to a pint and strain." *U. S.*

"Take of Pipsissewa *an ounce*; Distilled Water *a pint and a half* [Imperial measure]. Boil to a pint, and strain." *Lond.*

"Take of Leaves of Winter-green, dried, *half an ounce* [avoirdupois]; Water *half a pint* [Imp. meas.]. Boil for ten minutes, in a covered vessel, and strain. The product should measure about *eight* [*fluid*]*ounces.*" *Dub.*

The medical properties and uses of pipsissewa have been detailed under the head of Chimaphila. One pint of the decoction may be given in the course of twenty-four hours. W.

DECOCTUM CINCHONÆ FLAVÆ. *U.S.* DECOCTUM CINCHONÆ. *Lond., Ed. Decoction of Yellow Bark.*

"Take of Yellow Bark, bruised, *an ounce;* Water *a pint.* Boil for ten minutes in a covered vessel, and strain the liquor while hot." *U.S.*

The *London College* boils *ten drachms* of yellow bark, bruised, with *a pint* [Imperial measure] of distilled water, for a quarter of an hour, in a covered vessel, and strains while hot. The *Edinburgh College* boils an ounce of the yellow bark, bruised, with *twenty-four fluidounces* of water, for ten minutes, allows the decoction to cool, then filters it, and evaporates to *sixteen fluidounces.*

DECOCTUM CINCHONÆ PALLIDÆ. *Lond.* DECOCTUM CINCHONÆ. *Ed., Dub. Decoction of Pale Bark.*

The *London* and *Edinburgh Colleges* prepare this in the same manner as the *Decoction of Yellow Bark.* The *Dublin College* takes *half an ounce* (avoirdupois) of pale bark, in coarse powder, and *half a pint* (Imp. meas.) of water, boils for ten minutes in a covered vessel, and strains while hot.

DECOCTUM CINCHONÆ RUBRÆ. *U.S., Lond.* DECOCTUM CINCHONÆ. *Ed. Decoction of Red Bark.*

The *U. S., London,* and *Edinburgh* Pharmacopœias direct this to be prepared in the same manner as the Decoction of Yellow Bark.

The virtues of Peruvian bark, though extracted more rapidly by decoction than by infusion, are materially impaired by long boiling, in consequence of the changes effected in its constituents, either by their mutual reaction, or by the agency of atmospheric oxygen, or by both causes united. To prevent this result, the process is directed to be performed in a covered vessel, and to be continued only ten minutes. But even with these precautions, a considerable precipitate takes place in the decoction upon cooling, which is thus rendered turbid. According to Pelletier, besides the kinates of cinchonia and quinia, the water dissolves gum, starch, yellow colouring matter, kinate of lime, tannin, and a portion of cinchonic red, with a minute quantity of fatty matter. But the tannin and starch, at the boiling temperature, unite to form a compound insoluble in cold water; and, when the decoction is allowed to cool, this compound is precipitated, together with a portion of the cinchonic red and fatty matter, which carry with them also a considerable quantity of the alkaline principle of the bark. (*Journ. de Pharm.*, vii. 119.) Hence the decoction is ordered to be strained while hot, so that the portion of active matter precipitated may be mingled by agitation with the liquor, and not be lost. Pelletier recommends that a larger proportion of water, sufficient to retain the alkali in solution, be employed, that the decoction be filtered when cold, and then sufficiently concentrated by evaporation. This plan has been adopted by the Edinburgh College, but is unnecessarily tedious. A better mode is to add to the liquid some acid which may form with the quinia and cinchonia compounds more soluble than the native salts. Lemon juice has been long employed as a useful addition to the decoction of cinchona, and we can now understand the manner in which it acts. Sulphuric acid in excess answers the same purpose. By acidulating the pint of water employed in preparing the decoction with a fluidrachm of the aromatic or diluted sulphuric acid, we shall probably enable the menstruum to extract all the virtues of the bark. The propriety of such an addition is confirmed by the experiments of *MM. Henry, Jun.*, and *Plisson*, who have ascertained that portions of the alkalies exist in the bark connected with the colouring matter in the form of insoluble compounds, and that it is impossible, therefore, completely to exhaust the bark by water alone. There may, however, be some diversity of action in the different salts of quinia and cinchonia; and the native kinates may, under certain circumstances, be most efficient.

Numerous substances produce precipitates with this decoction; but comparatively few affect its activity as a medicine. (See *Infusum Cinchonæ.*) Tannic acid and the substances containing it should be excluded from the decoction; as it forms salts with the alkaline principles of the bark, which are either insoluble or but slightly soluble in water. The alkalies, alkaline earths, and salifiable bases generally should also be excluded; because, uniting with the kinic acid, they precipitate the quinia and cinchonia.

The dose of the decoction is two fluidounces, to be repeated more or less frequently according to circumstances. Two drachms of orange peel, added to the decoction while still boiling hot, improve its flavour, and render it more acceptable to the stomach. W.

DECOCTUM CORNÛS FLORIDÆ. *U. S. Decoction of Dogwood.*

"Take of Dogwood [bark], bruised, *an ounce;* Water *a pint.* Boil for ten minutes in a covered vessel, and strain the liquor while hot." *U. S.*

This decoction has been proposed as a substitute for that of Peruvian bark; but, though possessed of analogous properties, it is much inferior in efficacy, and is not likely to be extensively employed so long as the Peruvian tonic is attainable. The dose is two fluidounces. W.

DECOCTUM CYDONII. *Lond. Decoction of Quince Seed.*

"Take of Quince [seeds] *two drachms;* Distilled Water *a pint* [Imperial measure]. Boil over a slow fire for ten minutes; then strain." *Lond.*

This decoction is viscid, nearly colourless, insipid, and inodorous; and consists chiefly of the mucilaginous principle of the quince seeds dissolved in water. For an account of the properties and uses of this mucilage see *Cydonia.* It is only employed externally. As it speedily undergoes decomposition, it should be used immediately after being prepared. W.

DECOCTUM DULCAMARÆ. *U. S., Lond., Ed., Dub. Decoction of Bittersweet.*

"Take of Bittersweet, bruised, *an ounce;* Water *a pint and a half.* Boil down to a pint, and strain." *U. S.*

The processes of the *London* and *Edinburgh Colleges* correspond with the above. The *Dublin College* boils *half an ounce* (avoirdupois) of the bittersweet with *half a pint* (Imperial measure) of water, for ten minutes, in a covered vessel, and strains.

The slender twigs of the bittersweet are the part employed. Their properties and uses have been already detailed under the head of *Dulcamara.* The dose of the decoction is from one to two fluidounces three or four times a day, or more frequently. W.

DECOCTUM GALLÆ. *Lond. Decoction of Galls.*

"Take of Galls, bruised, *two ounces and a half;* Distilled Water *two pints* [Imperial measure]. Boil to a pint, and strain." *Lond.*

For the properties of this decoction and its uses, see *Galla* in the first part of this work. The dose internally would be from half a fluidounce to a fluidounce; but it is better adapted for external or local use. W.

DECOCTUM GRANATI. *Lond. Decoction of Pomegranate.*

"Take of Pomegranate [rind] *two ounces;* Distilled Water *a pint and a half* [Imperial measure]. Boil down to a pint, and strain." *Lond.*

The dose of this decoction is a fluidounce. For its uses see *Granatum.*

DECOCTUM GRANATI RADICIS. *Lond. Decoction of Pomegranate Root.*

"Take of Pomegranate Root, sliced, *two ounces;* Distilled Water *two pints* [Imperial measure]. Boil to a pint and strain." *Lond.*

For the uses and dose of this decoction, see *Granati Radicis Cortex.*

DECOCTUM GUAIACI. *Ed.* *Decoction of Guaiacum Wood.*

"Take of Guaiac turnings *three ounces;* Raisins *two ounces;* Sassafras [root] rasped, and Liquorice Root bruised, each, *one ounce;* Water *eight pints* [Imperial measure]. Boil the Guaiac and Raisins gently with the Water down to five pints, adding the Liquorice and Sassafras towards the end. Strain the decoction." *Ed.*

This is the old *decoction of the woods.* Notwithstanding its former reputation, it is little more than a demulcent drink; for water is capable of dissolving but a minute proportion of the active matter of guaiacum wood, and one ounce of sassafras root can impart no appreciable activity to five pints of menstruum. It was thought useful in chronic rheumatism and cutaneous affections, and as an adjuvant to a mercurial course in syphilis, or an alterative course of antimonials. As the patient was directed to be kept warm during its use, it no doubt acted favourably in some instances as a mere diluent, by promoting perspiration. From one to two pints may be taken in the course of the day, in doses of about four fluidounces. W.

DECOCTUM HÆMATOXYLI. *U. S., Lond., Ed., Dub.* *Decoction of Logwood.*

"Take of Logwood, rasped, *an ounce;* Water *two pints.* Boil down to a pint, and strain." *U. S.*

The *London College* takes *ten drachms* to *a pint and a half* [Imperial measure], boils to a pint, and strains.

"Take of Logwood, in chips, *one ounce*; Water *a pint* [Imperial measure]; Cinnamon, *one drachm,* in powder. Boil the Logwood in the Water down to ten fluidounces, adding the Cinnamon towards the end; and then strain." *Ed.*

The *Dublin College* boils *an ounce* (avoirdupois) of logwood with *half a pint* (Imp. meas.) of water for ten minutes, in a covered vessel, and strains.

This is an excellent astringent in diarrhœa; particularly in that form of it which succeeds the cholera infantum of this climate, or occurs as an original complaint in children during summer. The dose for an adult is two fluidounces, for a child about two years old, two or three fluidrachms, repeated several times a day. A little bruised cinnamon may often be added with advantage at the end of the boiling, as directed by the Edinburgh College. W.

DECOCTUM HORDEI. *U. S., Lond., Dub.* *Decoction of Barley.*

"Take of [Pearl] Barley *two ounces;* Water *four pints and a half.* First wash away, with cold water, the extraneous matters which adhere to the Barley; then pour upon it half a pint of the Water, and boil for a short time. Having thrown away this water, pour the remainder boiling hot upon the Barley; then boil down to two pints, and strain." *U. S.*

The process of the *London* College does not essentially differ from the above. The *Dublin College* washes *an ounce and a half* (avoirdupois) of barley in cold water, rejects the washings, and then boils for twenty minutes with a *pint and a half* (Imperial measure) of water, in a covered vessel, and strains.

Barley water, as this decoction is usually called, is much employed as a nutritive drink in febrile and inflammatory complaints, and, from the total absence of irritating properties, is peculiarly adapted to cases in which the gastric or intestinal mucous membrane is inflamed. As the stomach of those for whom it is directed is often exceedingly delicate, and apt to revolt against anything having the slightest unpleasantness of flavour, it is important that the decoction should be properly made; and, though the office of preparing it generally falls to nurses, yet the introduction of the process into the Pharmacopœia is not without advantage, as a formula is thus ever before the physician, by which he may give his directions, with the certainty, if obeyed, of having a good prepa-

ration. The use of the washing with cold water, and of the first short boiling, is completely to remove any mustiness, or other disagreeable flavour, which the barley may have acquired from exposure.

Off. Prep. Decoctum Hordei Compositum; Enema Aloës; Enema Assafœtidæ; Enema Terebinthinæ. W.

DECOCTUM HORDEI COMPOSITUM. *Lond.* MISTURA HORDEI. *Ed.* *Compound Decoction of Barley.*

"Take of Decoction of Barley *two pints* [Imperial measure]; Figs, sliced, *two ounces and a half;* fresh Liquorice Root, bruised, *five drachms;* Raisins, stoned, *two ounces and a half;* Distilled Water *a pint* [Imperial measure]. Boil down to two pints [Imp. meas.], and strain." *Lond.*

"Take of Pearl-Barley, Figs, sliced, Raisins freed of the seeds, of each, *two ounces and a half;* Liquorice Root, sliced and bruised, *five drachms;* Water *five pints and a half* [Imperial measure]. Clean the Barley, if necessary, by washing it with cold water; boil it with four pints and a half of the Water down to two pints; add the Figs, Raisins, and Liquorice Root, with the remaining pint of Water; and again boil down to two pints; then strain." *Ed.*

The compound decoction of barley, in addition to the demulcent and nutritive properties of the simple, is somewhat laxative, and may be preferably employed where there is a tendency to constipation. But it is so often necessary to vary the nature of the sapid ingredients to suit the taste of the patient, that it would be better to leave the preparation entirely to extemporaneous prescription. W.

DECOCTUM LINI COMPOSITUM. *Dub.* *Compound Decoction of Flaxseed.*

"Take of Linseed *one ounce;* Liquorice Root, bruised, *half an ounce;* Water *one pint and a half* [Imperial measure]. Boil for ten minutes in a covered vessel, and strain while hot." *Dub.* The weights employed are the avoirdupois.

Flaxseed is, we think, a better subject for infusion than decoction, by which the oil is partially evolved, and the preparation rendered unpleasant. W.

DECOCTUM MEZEREI. *Ed.* *Decoction of Mezereon.*

"Take of Mezereon, in chips, *two drachms;* Liquorice Root, bruised, *half an ounce;* Water *two pints* [Imperial measure]. Mix them and boil down with a gentle heat to a pint and a half, and then strain." *Ed.*

This preparation affords a convenient mode of exhibiting mezereon, the acrimony of which is qualified by the demulcent principles of the liquorice root. For an account of its medical applications, see *Mezereum.* The dose is from four to eight fluidounces four times a day. W.

DECOCTUM MYRRHÆ. *Dub.* *Decoction of Myrrh.*

"Take of Myrrh *two drachms* [Dub. weight]; Water *eight* [*fluid*]*ounces and a half.* Triturate the Myrrh with the Water gradually added; then boil for ten minutes, in a covered vessel, and strain. The product should measure about eight [fluid]ounces." *Dub.*

It does not appear to us that myrrh is a suitable substance for decoction. Its active principles are but very sparingly imparted to water. W.

DECOCTUM PAPAVERIS. *Lond., Ed., Dub.* *Decoction of Poppy.*

"Take of Poppy [Capsules], sliced, *four ounces;* Distilled Water *four pints* [Imperial measure]. Boil for a quarter of an hour, and strain." *Lond.*

The *Edinburgh* process differs from the above only in the proportion of water, employing *three pints* (Imp. meas.). The *Dublin College* boils *four ounces*

(avoirdupois) with *three pints* (Imp. meas.) of water, for ten minutes, in a covered vessel, and strains.

This decoction is used as an anodyne fomentation in painful tumours, and superficial cutaneous inflammation or excoriation. It is recommended not to reject the seeds; as their oil, suspended in the water by the mucilage of the capsules, adds to the emollient virtues of the preparation. W.

DECOCTUM PAREIRÆ. *Lond.* *Decoction of Pareira Brava.*

"Take of Pareira Brava, sliced, *ten drachms;* Distilled Water *a pint and a half* [Imperial measure]. Boil down to a pint, and strain." *Lond.*

The dose of this preparation is from one to two fluidounces three or four times a day. W.

DECOCTUM QUERCÛS ALBÆ. *U.S.* *Decoction of White Oak Bark.* DECOCTUM QUERCÛS. *Lond, Ed., Dub.* *Decoction of Oak Bark.*

"Take of White Oak Bark, bruised, *an ounce;* Water *a pint and a half.* Boil down to a pint, and strain." *U. S.*

The *London* and *Edinburgh Colleges* take *ten drachms* of oak bark and *two pints* (Imperial measure) of distilled water, and boil to a pint; the *Dublin College* takes *an ounce and a half* (avoirdupois) of the bark; and *a pint and a half* (Imp. meas.) of water, and boils for ten minutes.

This decoction contains the tannin, bitter principle, and gallic acid of oak bark. It affords precipitates with the decoction of Peruvian bark and other substances containing vegetable alkalies, with solution of gelatin, and with most metallic salts, particularly those of iron. Alkaline solutions diminish or destroy its astringency. Its uses have been already detailed. The dose is a wineglassful, frequently repeated. W.

DECOCTUM SARSAPARILLÆ. *Dub.* DECOCTUM SARSÆ. *Lond.* DECOCTUM SARZÆ. *Ed.* *Decoction of Sarsaparilla.*

"Take of Sarsaparilla, *five ounces;* Distilled Water *four pints* [Imperial measure]. Boil down to two pints, and strain." *Lond.*

"Take of Sarza, in chips, *five ounces;* boiling Water *four pints* [Imperial measure]. Digest the root in the Water for two hours at a temperature somewhat below ebullition, take out the root, bruise it, replace it, boil down to two pints [Imp. meas.], and then squeeze out the decoction and strain it." *Ed.*

The *Dublin College* digests *two ounces* (avoirdupois) of the sliced root with *a pint and a half* (Imp. meas.) of water for an hour, then boils for ten minutes, in a covered vessel, cools, and strains.

There can be no occasion for the digestion directed by the Edinburgh College, as, if the root is sliced and well bruised, all its ingredients that are soluble in water may be extracted by a length of boiling sufficient to reduce the liquor to one-half. An idea was formerly entertained that the virtues of sarsaparilla resided in its fecula, the extraction of which was, therefore, the main object of the decoction. Hence the long boiling ordered by the London and Edinburgh Colleges. But this opinion is now admitted to be erroneous. The activity of the root is believed to depend upon one or more acrid principles, soluble to a certain extent in water cold or hot, and either volatilized, or rendered inert by chemical change, at the temperature of 212°. This fact appears to be demonstrated by the experiments of Pope,* Hancock,† Soubeiran,‡ Beral, and others.

* Trans. of the Medico-Chirurg. Society of London, vol. xii. p. 344.

† Trans. of the Medico-Botan. Society of London. See also Journ. of the Phil. Col. of Pharm., vol. i. p. 295. The observations of Dr. Hancock are entitled to much credit, as he practised long in South America, in the neighbourhood of the best sarsaparilla regions.

‡ Journ. de Pharmacie, tom. xvi. p. 38.

Hancock makes the following observations. "After long boiling, the peculiar odour which rises abundantly on the coction of good *sarsa* is almost extinguished. From the sarsa prepared in this way, I found no sensible results upon any patient, nor were its peculiar nauseating, drowsy, and racking effects produced by a large quantity, although the decoction of six or eight ounces was tried at a dose. These experiments having been carried to a sufficient length, most of the same patients recovered under the use of the sarsa, taken from the same parcels as before, but now prepared by simple maceration in hot water, *i. e.*, affused in a boiling state, and kept near the boiling state for some hours. In all cases the sarsa was directed to be well bruised in large mortars, and in the mean time all other remedies were abstained from, which might, in any way, affect the result." Soubeiran macerated one portion of bruised sarsaparilla in cold water for twenty-four hours; infused another portion in boiling water, and digested with a moderate heat for two hours; boiled a third portion bruised, and a fourth unbruised, in water for two hours; and in each instance used the same relative quantities. Testing these various preparations by the taste, he found the cold and hot infusions scarcely different in this respect; and both possessed of a stronger odour and more acrid taste than the decoctions, of which that prepared with the bruised root was the strongest. Beral has proved that *sarsaparillin*, which is believed to be the active principle of the drug, is volatile. From all these facts the inference is obvious, that the best method of imparting the virtues of sarsaparilla to water is either by cold or hot infusion. Digestion for some hours in water maintained at a temperature of 180° or somewhat less, in a covered vessel, has strong testimony in its favour. Percolation in a displacement apparatus, if properly conducted, is a convenient, and no doubt efficient mode of exhausting the root, so far as water will effect that object. Decoction is the worst method; and the longer it is continued, the weaker will be the preparation. Accordingly, in the last edition of the U. S. Pharmacopœia, an infusion of sarsaparilla has been substituted for the simple decoction. It is probable that, as in the case of the Peruvian bark, a boiling of ten or fifteen minutes might be advantageously resorted to, when circumstances require the preparation to be made in less time than is requisite for infusion. In every instance the root should be thoroughly bruised, or reduced to a coarse powder, thus obviating the necessity for a long maceration, merely to overcome the cohesion of its fibres.

Precipitates are produced by various substances with the decoction of sarsaparilla; but it has not been ascertained how far such substances interfere with its activity. Those which merely throw down the fecula do not injure the preparation.

The simple decoction of sarsaparilla is chiefly used in the preparation of the compound decoction. If given alone, it may be administered in the dose of four or six fluidounces four times a day.

Off. Prep. Decoctum Sarsæ Compositum. W.

DECOCTUM SARSAPARILLÆ COMPOSITUM. *U. S.*, *Dub.* DECOCTUM SARSÆ COMPOSITUM. *Lond.* DECOCTUM SARZÆ COMPOSITUM. *Ed.* *Compound Decoction of Sarsaparilla.*

Take of Sarsaparilla, sliced and bruised, *six ounces;* Bark of Sassafras Root, sliced, Guaiacum Wood, rasped, Liquorice Root, bruised, each, *an ounce;* Mezereon, sliced, *three drachms;* Water *four pints.* Macerate for twelve hours; then boil for a quarter of an hour, and strain." *U. S.*

"Take of Decoction of Sarsaparilla, boiling hot, *four pints* [Imp. meas.]; Sassafras [root], sliced, Guaiacum Wood, rasped, fresh Liquorice Root, bruised, each, *ten drachms;* Mezereon *three drachms.* Boil for a quarter of an hour, and strain." *Lond.*

The *Edinburgh* process differs from the London only in the quantity of mezereon, which in the former is *half an ounce.* The *Dublin College* takes *two ounces* (avoirdupois) of the sarsaparilla, *two drachms* (Dub. weight), each, of the sassafras, guaiacum wood, and liquorice root, *a drachm* (Dub. weight) of the mezereon root-bark, and *a pint and a half* (Imp. meas.) of boiling water; digests all together, in a close vessel, for an hour, then boils for ten minutes, cools, and strains.

The process of the U. S. Pharmacopœia differs essentially from those of the London and Edinburgh Colleges in this respect, that, instead of taking the simple decoction of sarsaparilla prepared by long boiling, it mixes the bruised root immediately with the other ingredients, and boils the whole together for a few minutes. Thus, the sarsaparilla does not undergo a longer boiling than the other substances; and the preparation is brought more nearly into accordance with the present state of knowledge in relation to this valuable drug. (See *Decoctum Sarsaparillæ.*) The direction in the edition of the U. S. Pharmacopœia for 1850, to macerate for twelve hours, is an improvement. The Dublin process is preferable to those of the other British Colleges.

This decoction is an imitation of the celebrated *Lisbon diet drink.* The sarsaparilla and mezereon are the active ingredients; the guaiacum wood imparting scarcely any of its virtues, and the sassafras and liquorice serving little other purpose than to communicate a pleasant flavour.

If prepared with good sarsaparilla, and with a due regard to the practical rules which may now be considered as established, the decoction may be used with great advantage as a gentle diaphoretic and alterative in secondary syphilis, either alone, or as an adjuvant to a mercurial course; also in certain scrofulous and other depraved conditions of the system, in chronic rheumatism, and in various obstinate cutaneous affections. The dose is from four to six fluidounces three or four times a day. The patient during its use should wear flannel next the skin, and avoid unnecessary exposure to changes of temperature.* W.

DECOCTUM SCOPARII. *Dub.* *Decoction of Broom.*

"Take of Broom-tops, dried, *half an ounce* [avoirdupois]; Water *half a pint* [Imperial measure]. Boil for ten minutes in a covered vessel, and strain. The product should measure about eight [fluid]ounces." *Dub.*

DECOCTUM SCOPARII COMPOSITUM. *Lond.* DECOCTUM SCOPARII. *Ed.* *Compound Decoction of Broom.*

"Take of Broom, Juniper, bruised, Dandelion, bruised, each, *half an ounce;* Distilled Water *a pint and a half* [Imperial measure]. Boil down to a pint [Imp. meas.], and strain." *Lond.*

"Take of Broom-tops, and Juniper-tops, of each, *half an ounce;* Bitartrate

* The *Decoction of Zittmann* (Decoctum Zitmanni) is a preparation of sarsaparilla much used in Germany, for similar purposes with our compound decoction of sarsaparilla; and, as it has attracted some attention in this country as a remedy in obstinate ulcerative affections, we give the formula of the Prussian Pharmacopœia, which is generally followed in its preparation: "Take of sarsaparilla *twelve ounces;* spring water *ninety pounds.* Digest for twenty-four hours; then introduce, enclosed in a small bag, *an ounce and a half* of saccharine alum (a paste formed of alum ℥vi, white lead ℥vi, sulphate of zinc ℥iij, white sugar ℥iss, white of egg and distilled vinegar, each *q. s.*), *half an ounce* of calomel, and *a drachm* of cinnabar. Boil to thirty pounds, and near the end of the boiling add of aniseed, fennel-seed, each, *half an ounce,* senna *three ounces,* liquorice root *an ounce and a half.* Put aside the liquor under the name of THE STRONG DECOCTION. To the residue add *six ounces* of sarsaparilla and *ninety pounds* of water. Boil to thirty pounds, and near the end add lemon-peel, cinnamon, cardamom, liquorice, of each, *three drachms.* Strain, and set aside the liquor under the name of THE WEAK DECOCTION." Mercury was detected by Wiggers in this decoction in very small proportion. It should not be prepared in metallic vessels, lest the mercurial in solution should be decomposed. The decoction may be drunk freely.

of Potassa *two drachms and a half;* Water *a pint and a half* [Imp. meas.]. Boil them together down to a pint [Imp. meas.], and then strain." *Ed.*

This decoction may be used as an adjuvant to more powerful diuretics in dropsy. From half a pint to a pint may be taken during the day. The simple decoction of the Dublin College is twice as strong with broom as the compound decoction. W.

DECOCTUM SENEGÆ. *U. S., Lond. Decoction of Seneka.*

"Take of Seneka, bruised, *an ounce;* Water *a pint and a half.* Boil down to a pint, and strain." *U. S.*

The *London College* boils *ten drachms* of the root with *two pints* of distilled water to a pint; but the relation of the Imperial measure used by this College to the common wine measure is such, that the proportions in the decoction are essentially the same as those of the U. S. Pharmacopœia.

It is customary to add to the seneka an equal weight of liquorice root, which serves to cover its taste, and in some measure to obtund its acrimony. The virtues and practical application of seneka have been already treated of. (See *Senega.*) The dose of the decoction is about *two fluidounces* three or four times a day, or a tablespoonful every two or three hours. W.

DECOCTUM TARAXACI. *Lond., Ed. Decoction of Dandelion.*

"Take of Dandelion, bruised, *four ounces;* Distilled Water *a pint and a half* [Imperial measure]. Boil to a pint, and strain." *Lond.*

The *Edinburgh College* takes *seven ounces* of the fresh herb and root, and *two pints* [Imperial measure] of water, boils to one pint [Imperial measure], and strains.

This decoction is most efficient when prepared from the root alone. The dose is a wineglassful two or three times a day. (See *Taraxacum.*) W.

DECOCTUM TORMENTILLÆ. *Lond. Decoction of Tormentil.*

"Take of Tormentil, bruised, *two ounces;* Distilled Water *a pint and a half* [Imperial measure]. Boil down to a pint, and strain." *Lond.*

This decoction is astringent, and may be given in the dose of one or two fluidounces, three or four times a day. W.

DECOCTUM ULMI. *Lond. Decoction of Elm Bark.*

"Take of Elm [bark], bruised, *two ounces and a half;* Distilled Water *two pints* [Imperial measure]. Boil down to a pint, and strain." *Lond.*

This decoction, being prepared from the bark of the European elm, is not used in this country. It has had some repute in England as a remedy for certain cutaneous disorders. From four to six fluidounces are given two or three times a day. W.

DECOCTUM UVÆ URSI. *U.S., Lond., Dub. Decoction of Uva Ursi.*

"Take of Uva Ursi *an ounce;* Water *twenty fluidounces.* Boil down to a pint, and strain." *U. S.*

"Take of Uva Ursi, bruised, *an ounce;* Distilled Water *a pint and a half* [Imperial measure]. Boil down to a pint, and strain." *Lond.*

"Take of Uva Ursi, bruised, *half an ounce* [avoirdupois]; Water *half a pint* [Imp. meas.]. Boil for ten minutes in a covered vessel, and strain. The product should measure about eight [fluid]ounces." *Dub.*

This decoction contains the tannin, extractive, and gallic acid of the leaves. For an account of its uses see *Uva Ursi.* The dose is from one to two fluidounces three or four times a day. W.

EMPLASTRA.

Plasters.

Plasters are solid compounds intended for external application, adhesive at the temperature of the human body, and of such a consistence as to render the aid of heat necessary in spreading them. Most of them have as their basis a compound of olive oil and litharge, constituting the Emplastrum Plumbi of the United States Pharmacopœia. Those plasters which contain none of the compound of oil and litharge, owe their consistence and adhesiveness to resinous substances, or to a mixture of these with wax and oleaginous matter.

In the preparation of the plasters, care is requisite that the heat employed be not sufficiently elevated to produce decomposition, nor so long continued as to drive off any volatile ingredient upon which the virtues of the preparation may in any degree depend. After having been prepared, they are usually shaped into cylindrical rolls, and wrapped in paper to exclude the air. Plasters should be firm at ordinary temperatures, should spread easily when heated, and, after being spread, should remain soft, pliable, and adhesive, without melting at the heat of the human body. When long kept, they are apt to change colour and to become hard and brittle; and as this alteration is most observable upon their surface, it must depend chiefly upon the action of the air, which should therefore be as much as possible excluded. The defect may usually be remedied by melting the plaster with a moderate heat, and adding a sufficient quantity of oil to give it the due consistence.

Plasters are prepared for use by spreading them upon leather, linen, or muslin, according to the particular purposes they are intended to answer. Leather is most convenient when the application is made to the sound skin, linen or muslin when the plaster is used as a dressing to ulcerated or abraded surfaces, or with the view of bringing and retaining together the sides of wounds. The leather usually preferred is white sheep skin. A margin about a quarter or half an inch broad should usually be left uncovered, in order to facilitate the removal of the plaster, and to prevent the clothing in contact with its edges from being soiled. An accurate outline may be obtained by pasting upon the leather a piece of paper, so cut as to leave in the centre a vacant space of the required dimensions, and removing the paper when no longer required. The same object may sometimes be accomplished by employing two narrow rulers of sheet tin, graduated in inches, and so shaped that each of them may form two sides of a rectangle. (See the figure p. 785.) These may be applied in such a manner as to enclose within them any given rectangular space, and may be fixed by weights upon the leather while the plaster is spread. For any other shape, as in the instance of plasters for the breast, pieces of tin may be employed having a vacuity within, corresponding to the required outline. The spreading of the plaster is most conveniently accomplished by means of a peculiar iron instrument employed for the purpose; though a common spatula will answer. This may be heated by means of a spirit lamp. Care must be taken that the instrument be not so hot as to discolour or decompose the plaster, and special care is requisite in the case of those plasters which contain a volatile ingredient. A sufficient portion of the plaster should first be melted by the heated instrument, and, having been received on a piece of coarse stiff paper, or in a shallow tin tray open on one side, should, when nearly cool, be transferred to the leather, and applied quickly and evenly over its extended surface. By this plan the melted plaster is prevented from penetrating the leather, as it is apt to do when applied too hot. Before removing the paper from the edge of the plaster, if it has become so hard as to crack, the iron

should be drawn over the line of junction.* When linen or muslin is used, and the dimensions of the portion to be spread are large, as is often the case with adhesive plaster, the best plan is to pass the cloth "on which the plaster has been laid, through a machine formed of a spatula, fixed by screws at a proper distance from a plate of polished steel." A machine for spreading plasters is described by M. Hérent in the *Journ. de Pharm. et de Chim.* (3e sér., ii. 403).† W.

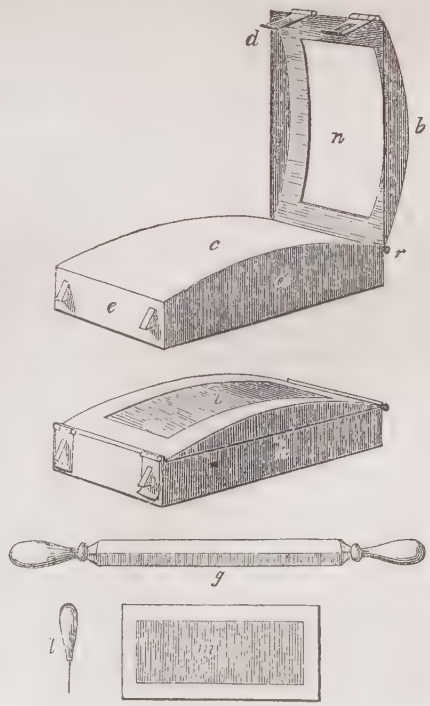
EMPLASTRUM AMMONIACI. *U. S., Lond., Ed., Dub. Ammoniac Plaster.*

"Take of Ammoniac *five ounces;* Diluted Acetic Acid *half a pint.* Dissolve the Ammoniac in the Diluted Acetic Acid, and strain; then evaporate the solution by means of a water-bath, stirring constantly until it acquires a proper consistence." *U. S.*

The *London College* takes *five ounces* of prepared ammoniac, and *eight fluidounces* of diluted acetic acid; dissolves the ammoniac in the acid; and evaporates the solution by a slow fire, stirring constantly, to the proper consistence. The *Edinburgh College* takes *five ounces* of ammoniac and *nine fluidounces* of distilled vinegar; dissolves the ammoniac in the vinegar, and evaporates over the vapour-bath, frequently stirring. The *Dublin College* dissolves *four ounces* (avoirdupois) of ammoniac, coarsely powdered, in *four fluidounces* of proof spirit, and then evaporates, by means of a steam or water-bath, stirring constantly until it acquires a proper consistence.

* The reader is referred to the *Am. Journ. of Pharm.* (xxv. 29, and xxvi. 15), for descriptions of plaster spatulas, with contrivances for heating them, which he may sometimes find convenient.

† Within a few years it has been customary with apothecaries to employ an apparatus, such as that here figured, for preparing quantities of plasters. An oblong rectangular block of hard wood (*a e*) has its upper surface (*c*) gently convex. To this is attached by a movable joint (at *r*) a sheet iron frame (*b*), with an opening (*n*) of the dimensions of the plaster to be spread, and clasps (*d*) at the other end, by which this may be fixed to the block. Another portion of the apparatus is a wooden measure (*m*), by which the leather is cut out, and the margin marked. The leather thus prepared is laid on the convex surface of the block (*c*); the sheet iron frame is brought down on it evenly (as at *h i*); the plaster, previously melted, is poured on the leather in the centre, and, by means of an iron instrument (*g*), previously heated by a spirit lamp, is spread uniformly over the surface, the thickness being regulated by the frame against which the iron is pressed. Any excess of plaster is thus pressed over upon the frame. The point of a sharp instrument (*l*) is then drawn along the interior edge of the frame so as to separate the plaster from it, after which the clasps are unfastened and the plaster removed.



As ammoniac is not usually kept purified in our shops, the straining of the solution in the diluted acid is directed as the most convenient method of separating impurities. Dr. Duncan remarked that the plaster, prepared in iron vessels, "acquires an unpleasant dark colour, from being impregnated with iron; whereas, when prepared in a glass or earthenware vessel, it has a yellowish-white colour, and more pleasant appearance."

Medical Properties. The ammoniac plaster is stimulant, and is applied over scrofulous tumours and chronic swellings of the joints, to promote their resolution. It often produces a papular eruption, and sometimes occasions considerable inflammation of the skin. Dr. Duncan has described a fatal case of diffuse inflammation following its use in an instance of diseased knee-joint.

Off. Prep. Emplastrum Ammoniaci cum Hydrargyro. W.

EMPLASTRUM AMMONIACI CUM HYDRARGYRO. *U. S.*, *Lond.*, *Dub.* EMPLASTRUM AMMONIACI ET HYDRARGYRI. *Ed.* *Plaster of Ammoniac with Mercury.*

"Take of Ammoniac *a pound;* Mercury *three ounces;* Olive Oil *a fluidrachm;* Sulphur *eight grains.* Heat the Oil, and gradually add the Sulphur, constantly stirring, until they unite; then add the Mercury, and triturate until globules no longer appear. Boil the Ammoniac with sufficient water to cover it until they are mixed; then strain through a hair sieve, and evaporate, by means of a water-bath, until a small portion taken from the vessel hardens on cooling. Lastly, add the Ammoniac, while yet hot, gradually to the mixture of Oil, Sulphur, and Mercury, and thoroughly incorporate all the ingredients." *U. S.*

"Take of Prepared Ammoniac *a pound;* Mercury *three ounces;* Olive Oil *a fluidrachm;* Sulphur *eight grains.* Add the Sulphur gradually to the heated Oil, constantly stirring with a spatula, until they unite; then rub the Mercury with them until the globules disappear; lastly, gradually add the Ammoniac, previously melted, and mix the whole together." *Lond.*

The *Edinburgh* process corresponds closely with the above.

"Take of Ammoniac Plaster *four ounces;* Mercurial Plaster *eight ounces.* Mix them together by means of a steam or water-bath, and stir constantly until the mixture stiffens on cooling." *Dub.*

Of these processes the last is preferable, as the unpleasant odour of the sulphuretted oil is avoided, as well as the action of the sulphur upon the mercury, with which it must form an inactive sulphuret. When ammoniac not previously prepared is used, as it is not fusible by heat, it must be brought to the proper consistence by dissolving it in a small quantity of hot water, straining, and evaporating.

Medical Properties and Uses. This plaster unites with the stimulant power of the ammoniac the specific properties of the mercury, which is sometimes absorbed in sufficient quantity to affect the gums. It is used as a discutient in enlargement of the glands, tumefaction of the joints, nodes, and other indolent swellings, especially when dependent on a venereal taint. It is also sometimes applied over the liver in chronic hepatitis. W.

EMPLASTRUM ASSAFŒTIDÆ. *U. S.*, *Ed.* *Assafetida Plaster.*

"Take of Assafetida, Lead Plaster, each, *a pound;* Galbanum, Yellow Wax, each, *half a pound;* Alcohol *three pints.* Dissolve the Assafetida and Galbanum in the Alcohol with the aid of a water-bath, strain the liquor while hot, and evaporate to the consistence of honey; then add the Lead Plaster and Wax previously melted together, stir the mixture well, and evaporate to the proper consistence." *U. S.*

"Take of Litharge [Lead] Plaster and Assafetida, of each, *two ounces;* Galbanum and Bees'-wax, of each, *one ounce.* Liquefy the gum-resins together,

and strain them, then add the plaster and wax also in the fluid state, and mix them all thoroughly." *Ed.*

The directions of the U. S. Pharmacopœia indicate the mode in which the gum-resins may be brought to the liquid state before being incorporated with the other ingredients. Galbanum melts sufficiently by the aid of heat to admit of being strained; but this is not the case with assafetida, which must be prepared by dissolving it in a small quantity of hot water or alcohol, straining, and evaporating to the consistence of honey; and even galbanum may be most conveniently treated in the same way. Formerly these gum-resins were ordered merely to be melted and strained, and such is at present the direction of the Edinburgh Pharmacopœia, unless the term "liquefy" be considered as leaving to the operator the choice of the mode in which they should be brought into the liquid state.

This plaster may be advantageously applied over the stomach or abdomen, in cases of hysteria attended with flatulence, and to the chest or between the shoulders in hooping-cough. W.

EMPLASTRUM BELLADONNÆ. *U. S., Lond., Ed., Dub. Plaster of Belladonna.*

"Take of Resin Plaster *three ounces;* Extract of Belladonna *an ounce and a half.* Add the Extract to the Plaster, previously melted by the heat of a water-bath, and mix." *U. S.*

The *Edinburgh* and *Dublin* processes are the same as the above. The *London* differs in taking *three ounces*, each, of the extract and of soap plaster.

The most convenient method of forming this plaster is to rub the ingredients together in an earthenware mortar, placed in hot water, and then, having removed the mortar from the water-bath, to continue the trituration till the mixture cools. It should be prepared with the extract made according to the directions of the U. S. Pharmacopœia, which is deprived of the albumen and insoluble matter; as otherwise it is apt to be wanting in the due adhesiveness. The preparation is a useful anodyne application in neuralgic and rheumatic pains, and in dysmenorrhœa. We have seen the constitutional effects of belladonna result from its external use. W.

EMPLASTRUM CANTHARIDIS. *Lond., Ed., Dub. Plaster of Spanish Flies.*

See CERATUM CANTHARIDIS. *U. S.*

EMPLASTRUM CANTHARIDIS COMPOSITUM. *Ed. Compound Plaster of Spanish Flies.*

"Take of Venice Turpentine *four ounces and a half;* Burgundy Pitch and Cantharides, of each, *three ounces;* Bees'-wax *one ounce;* Verdigris *half an ounce;* White Mustard Seed and Black Pepper, of each, *two drachms.* Liquefy the Wax and Burgundy Pitch, add the Turpentine, and while the mixture is hot sprinkle into it the remaining articles, previously in fine powder, and mixed together. Stir the whole briskly as it concretes on cooling." *Ed.*

This is intended to be a powerful and speedy blistering plaster, and may probably prove beneficial in very urgent cases attended with much torpor of the skin; but great care should be observed not to allow it to remain on too long, as unpleasant and tedious ulceration, if not gangrene, might result. To the cases of children it is wholly inapplicable. W.

EMPLASTRUM CUMINI. *Lond. Cumin Plaster.*

"Take of Cumin, Caraway, Laurel [fruit], each, *three ounces;* Prepared Burgundy Pitch *three pounds;* Wax *three ounces;* Olive Oil, Water, each *a fluidounce and a half.* To the Pitch and Wax melted together add the dry

ingredients powdered, the Oil, and the Water; then evaporate to the proper consistence." *Lond.*

This is a gently stimulant plaster of an agreeable odour, and may be used when a very moderate rubefacient impression is indicated. The London College has inadvertently employed the name *Cyminum* in the Materia Medica list, and *Cuminum* here. W.

EMPLASTRUM FERRI. *U.S.*, *Lond.*, *Ed.*, *Dub.* EMPLASTRUM ROBORANS. *Iron Plaster. Strengthening Plaster.*

"Take of Subcarbonate of Iron *three ounces;* Lead Plaster *two pounds;* Burgundy Pitch *half a pound.* Add the Subcarbonate of Iron to the Lead Plaster and Burgundy Pitch, previously melted together, and stir them constantly until they thicken upon cooling." *U. S.*

The *London* and *Dublin* preparations are the same as the above, except that prepared *Thus* or frankincense is used in the former instead of Burgundy pitch, and peroxide of iron in the latter, instead of the subcarbonate.

"Take of Litharge Plaster *three ounces;* Resin *six drachms;* Olive Oil *three fluidrachms and a half;* Bees'-wax *three drachms;* Red Oxide of Iron [Subcarbonate of Iron, U. S] *one ounce.* Triturate the Oxide of Iron with the Oil, and add the mixture to the other articles previously liquefied by gentle heat. Mix the whole thoroughly." *Ed.*

This preparation has enjoyed some popular celebrity, under the impression that it strengthens the parts to which it is applied; whence it has derived the name of strengthening plaster. It is used in those conditions of the loins, larger muscles, and joints, which, though usually ascribed to debility, are in fact most frequently dependent on rheumatic or other chronic inflammatory affections, and, if relieved by the plaster, are so in consequence of the gentle excitation which it produces in the vessels of the skin. It may also, in some instances, give relief by affording mechanical support; but neither in this, nor in any other respect, can it be deemed very efficient. W.

EMPLASTRUM GALBANI COMPOSITUM. *U.S.* EMPLASTRUM GALBANI. *Lond. Compound Galbanum Plaster.*

"Take of Galbanum *eight ounces;* Turpentine *ten drachms;* Burgundy Pitch *three ounces;* Lead Plaster *three pounds.* To the Galbanum and Turpentine, previously melted together and strained, add first the Burgundy Pitch, and afterwards the Lead Plaster melted over a gentle fire, and mix the whole together." *U. S.*

The *London* process differs only in directing *an ounce* of turpentine instead of *ten drachms*, prepared galbanum instead of the crude, and prepared *Thus* or frankincense, instead of Burgundy pitch.

Before being employed in this process, the galbanum should be purified, as it often contains foreign matters which must injure the plaster. It may be freed from these by melting it with a little water or diluted alcohol, straining, and evaporating to the due consistence.

This plaster is an excellent local stimulant in chronic scrofulous enlargements of the glands and joints. We have employed it in some obstinate cases of this kind, which, after having resisted general and local depletion, blistering and other measures, have yielded under its use. As a discutient it is also employed in the induration which sometimes remains after the discharge of abscesses. It is said to have been useful in rickets when applied over the whole lumbar region, and has been recommended in chronic gouty or rheumatic articular affections. It should not be used in the discussion of tumours in which any considerable inflammation exists. W.

EMPLASTRUM GUMMOSUM. *Ed.* *Gum Plaster.*

"Take of Litharge Plaster [Emplastrum Plumbi] *four ounces;* Ammoniac, Galbanum, and Bees'-wax, of each, *half an ounce.* Melt the Gum-resins together and strain them; melt also together the Plaster and Wax; add the former to the latter mixture, and mix the whole thoroughly." *Ed.*

The addition of ammoniac adds little to the virtues of this plaster, which closely resembles the compound galbanum plaster in its effects. The galbanum and ammoniac are best prepared by dissolving them in a small quantity of hot water or diluted alcohol, straining the solution, and evaporating it to the proper consistence for mixing with the other ingredients.

Off. Prep. Emplastrum Saponis. W.

EMPLASTRUM HYDRARGYRI. *U.S., Lond., Ed., Dub.* *Mercurial Plaster.*

"Take of Mercury *six ounces;* Olive Oil, Resin, each, *two ounces;* Lead Plaster *a pound.* Melt the Oil and Resin together, and when they have become cool, rub the Mercury with them till the globules disappear; then gradually add the Lead Plaster, previously melted, and mix the whole together." *U. S.*

The *London College* takes *three ounces* of mercury, *a pound* of lead plaster, *a fluidrachm* of olive oil, and *eight grains* of sulphur; gradually adds the sulphur to the heated oil, constantly stirring with a spatula until they unite; then rubs the mercury with them until the globules disappear; and finally adds by degrees the lead plaster previously melted with a slow fire, and mixes the whole together. The *Edinburgh* process corresponds with that of the United States Pharmacopœia, except that only one-half of the quantity of materials is employed, and *nine fluidrachms* of olive oil are directed instead of an ounce.

The *Dublin College* substitutes a *fluidounce* of oil of turpentine for the two ounces of olive oil; but in other respects its process corresponds with that of the U. S. Pharmacopœia.

The sulphuretted oil employed by the London College is intended to facilitate the extinguishment of the mercury; but, as it operates by the union of the sulphur with the metal forming an inefficient sulphuret, it impairs the virtues of the plaster at least as much as it assists in its preparation. The melted resin and oil of the United States and Edinburgh processes are decidedly preferable.

This plaster is employed to produce the local effects of mercury upon venereal buboes, nodes, and other chronic tumefactions of the bones or soft parts, dependent on a syphilitic taint. In these cases it sometimes acts as a powerful discutient. It is frequently also applied to the side in chronic hepatitis or splenitis. In habits peculiarly susceptible to the mercurial influence, it occasionally affects the gums.

From observations made in France by Messrs. Serres, Gariel, Briquet, and others (*Archives Générales*, viii. 468, and 3*e sér.*, vi. 24), it appears that the mercurial plaster of the French Codex (*Emplastrum de Vigo cum Mercurio*) has the power, when applied over the eruption of small-pox, before the end of the third day from its first appearance, to check the progress of the eruption, and prevent suppuration and pitting. This operation of the plaster, so far from being attended with an increase of the general symptoms, seems to relieve them in proportion to the diminution of the local affection. It is also thought that the course of the disease is favourably modified when the mercurial impression is produced upon the system. That the local effect is not ascribable to the mere exclusion of air is proved by the fact, that the use of lead plaster was not followed by the same results. It is probable that other mercurial preparations would answer the same purpose; and the common mercurial ointment has, in our own hands, proved effectual in rendering the eruption upon the face to a consider-

able extent abortive, in one bad case of small-pox. But as the most successful results were obtained with the plaster above mentioned, we give the formula of the French Codex for its preparation. The weights mentioned are those of the French metrical pound. (See *table in the Appendix.*)

Emplastrum de Vigo cum Mercurio. "Take of simple plaster [lead plaster] *two pounds eight ounces;* yellow wax *two ounces;* resin *two ounces;* ammoniac, bdellium, olibanum, and myrrh, each, *five drachms;* saffron *three drachms;* mercury *twelve ounces;* turpentine [common European] *two ounces;* liquid storax *six ounces;* oil of lavender *two drachms.* Powder the gum-resins and saffron, and rub the mercury with the storax and turpentine in an iron mortar until completely extinguished. Melt the plaster with the wax and resin, and add to the mixture the powders and volatile oil. When the plaster shall have been cooled, but while it is yet liquid, add the mercurial mixture, and incorporate the whole thoroughly." This should be spread upon leather or linen cloth, and applied so as effectually to cover the face, or whatever other part it is desired to protect.

Off. Prep. Emplastrum Ammoniaci cum Hydrargyro. W.

EMPLASTRUM OPII. *U. S., Lond., Ed., Dub. Opium Plaster.*

"Take of Opium, in powder, *two ounces;* Burgundy Pitch *three ounces;* Lead Plaster *a pound;* Boiling Water *four fluidounces.* Melt together the Lead Plaster and Burgundy Pitch; then add the Opium previously mixed with the Water, and boil them over a gentle fire to the proper consistence." *U. S.*

"Take of Extract of Opium *an ounce;* Lead Plaster *eight ounces;* Prepared Thus [frankincense] *two ounces;* boiling Water *a fluidounce.* To the melted Thus add the Plaster melted with a slow fire, and the Extract previously mixed with the Water, and evaporate, with a slow fire, constantly stirring, until the proper consistence is obtained." *Lond.*

"Take of Powder of Opium *half an ounce;* Burgundy Pitch *three ounces;* Litharge Plaster [Lead Plaster] *twelve ounces.* Liquefy the Plaster and Pitch, add the Opium by degrees, and mix them thoroughly." *Ed.*

"Take of Opium, in very fine powder, *one ounce;* Resin Plaster *nine ounces.* Melt the Plaster by means of a steam or water bath, then add the Opium by degrees, and mix thoroughly." *Dub.*

The use of the water in the U. S. and London processes is to enable the opium to be more thoroughly incorporated with the other ingredients; but care should be taken that the moisture be well evaporated.

The opium plaster is thought to relieve rheumatic and other pains in the parts to which it is applied. W.

EMPLASTRUM PICIS. *Lond., Ed. Pitch Plaster.*

"Take of Prepared Burgundy Pitch *two pounds;* Prepared Thus [frankincense] *a pound;* Resin, Wax, each, *four ounces;* Expressed Oil of Nutmegs *an ounce;* Olive Oil, Water, each, *two fluidounces.* To the Thus, Pitch, Resin, and Wax, melted together, add the Oils and the Water. Then evaporate all, continually stirring, to the proper consistence." *Lond.*

"Take of Burgundy Pitch *one pound and a half;* Resin and Bees'-wax, of each, *two ounces;* Oil of Mace *half an ounce;* Olive Oil *one fluidounce;* Water *one fluidounce.* Liquefy the Pitch, Resin, and Wax with a gentle heat; add the other articles; mix them well together; and boil till the mixture acquires the proper consistence." *Ed.*

The simple "*Myristicæ Oleum*" of the London Materia Medica list, has become "*Myristicæ Oleum Expressum*" here. We presume that the Edinburgh *oil of mace*, in the above formula, though the term is not defined in the Pharmacopœia, has reference to the substance denominated, in the Edinburgh Materia Medica catalogue, *Myristicæ Adeps* or *concrete oil of nutmeg.* (See *Myristicæ Adeps*, page 487.)

This is a rubefacient plaster, applicable to catarrhal and other pectoral affections, chronic inflammation of the liver, and rheumatic pains in the joints and muscles. It often keeps up a serous discharge, which requires that it should be frequently renewed. The irritation which it sometimes excites is so great as to render its removal necessary. W.

EMPLASTRUM PICIS BURGUNDICÆ. *U.S.* *Burgundy Pitch Plaster.*

"Take of Burgundy Pitch *six pounds;* Yellow Wax *half a pound.* Melt them together, and stir them constantly till they thicken on cooling." *U. S.*

In this formula, the object of the wax is simply to give a proper consistence to the Burgundy pitch, and to prevent it from breaking in cold weather. W.

EMPLASTRUM PICIS CUM CANTHARIDE. *U.S.* EMPLASTRUM CALEFACIENS. *Dub.* *Plaster of Pitch with Spanish Flies. Warming Plaster.*

"Take of Burgundy Pitch *three pounds and a half;* Cerate of Spanish Flies *half a pound.* Melt them together by means of a water-bath, and stir them constantly till they thicken upon cooling." *U.S.*

The *Dublin College* employs the same ingredients, but has increased the proportion of Burgundy pitch to *five pounds and a half.*

This plaster is an excellent rubefacient, more active than Burgundy pitch, yet in general not sufficiently so to produce vesication. Still, however, in consequence of peculiar susceptibility of the skin in some individuals, it occasionally blisters; and it has been recommended to lessen the proportion of the flies. But, while such a reduction would render the plaster insufficiently active in most cases, it would not entirely obviate the objection; as the smallest proportion of flies would vesicate in certain persons, and even the Burgundy pitch alone sometimes produces the same effect. In whatever mode, therefore, this plaster may be prepared, it cannot always answer the expectations which may be entertained; and the only plan, when the skin of any individual has been found to be very susceptible, is to accommodate the proportions to the particular circumstances of the case. Much, however, may be accomplished by care in the preparation of the plaster, towards obviating its tendency to blister. If the flies of the *Ceratum Cantharidis* have been coarsely pulverized, the larger particles coming in contact with the skin, will exert upon the particular part to which they may be applied their full vesicatory effect, while, if reduced to a very fine powder, they would be more thoroughly enveloped in the other ingredients, and thus have their strength much diluted. Hence the cerate, when used as an ingredient of the warming plaster, should contain the cantharides as minutely divided as possible, and, if that usually kept is not in the proper state, a portion should be prepared for this particular purpose. A good plan, we presume, would be to keep the cerate used in this preparation, for a considerable time, at the temperature of 212°, and then strain it so as to separate the flies. (See *Ceratum Cantharidis.*) The mode frequently pursued of preparing the warming plaster by simply sprinkling a very small proportion of powdered flies upon the surface of Burgundy pitch is altogether objectionable. The U. S. process is that of the old Dublin Pharmacopœia. In the edition of the Dub. Pharmacopœia of 1850, the proportion of the Burgundy pitch has been increased so as considerably to diminish the strength of the preparation.

The warming plaster is employed in chronic rheumatism, and various chronic internal diseases attended with inflammation or an inflammatory tendency; such as catarrh, asthma, pertussis, phthisis, hepatitis, and the sequelæ of pleurisy and pneumonia. W.

EMPLASTRUM PLUMBI. *U. S., Lond.* EMPLASTRUM LITHARGYRI. *Ed., Dub. Lead Plaster. Litharge Plaster.*

"Take of Semivitrified Oxide of Lead, in very fine powder, *five pounds;* Olive Oil *a gallon;* Water *two pints.* Boil them together over a gentle fire, stirring constantly, until the Oil and Oxide of Lead unite into a plaster. It will be proper to add a little boiling water, if that employed at the commencement be nearly all consumed before the end of the process." *U. S.*

The above process is precisely that of the *London Pharmacopœia* of 1824. In the editions of that work for 1836 and 1851, the quantities directed are *six pounds* of the oxide of lead, *a gallon* of olive oil, and *two pints* of water; but, as the Imperial measure is employed, the proportions are in fact nearly the same as before.

The *Edinburgh College* orders *five ounces* of litharge, *twelve fluidounces* of olive oil, and *three fluidounces* of water. The *Dublin* process does not differ materially from that of the London and U. S. Pharmacopœias.

The importance of this plaster, as the basis of most of the others, requires a somewhat detailed account of the principles and manner of its preparation.

It was formerly thought that the oil and oxide of lead entered into direct union, and that the presence of water was necessary only to regulate the temperature, and prevent the materials from being decomposed by heat. The discovery, however, was afterwards made, that this liquid was essential to the process; and that the oil and oxide alone, though maintained at a temperature of 220°, would not combine; while the addition of water, under these circumstances, would produce their immediate union. It was now supposed that the oil was capable of combining only with the hydrated oxide of lead, and that the use of the water was to bring the oxide into that state; and, in support of this opinion, the fact was advanced that the hydrated oxide of lead and oil would form a plaster, when heated together without any free water. But, since the general reception of Chevreul's views in relation to oils and their combinations with alkalies and other metallic oxides, the former opinions have been abandoned; and it is now admitted that the preparation of the lead plaster affords a genuine example of saponification, as explained by that chemist. A reaction takes place between the oil and water, resulting in the development of a sweetish substance called *glycerin*, and of two acid bodies, the *oleic* and *margaric acids*, to which, when animal fat is employed instead of olive oil, a third is added, namely, the *stearic*. The plaster is formed by a union of these acids with the oxide, and, prepared according to the directions of the Pharmacopœias, is in fact an oleo-margarate of lead. The glycerin remains dissolved in the water, or mechanically mixed with the plaster. That such is the correct view of the nature of this compound is evinced by the fact, that, if the oxide of lead be separated from the plaster by digestion at a moderate heat in very dilute nitric acid, the fatty matter which remains will unite with litharge with the greatest facility, without the intervention of water. According to a more recent chemical view, the fixed oils are compounds of the oily acids mentioned and *oxide of glyceryle*. When boiled with the oxide of lead and water, the oily acids combine with the metallic oxide to form the plaster, and the oxide of glyceryle takes an equivalent of water and becomes glycerin. *Glyceryle* is a hypothetical compound of carbon and hydrogen (C_6H_7), which unites with five equivalents of oxygen to form oxide of glyceryle ($C_6H_7O_5$), also a hypothetical substance, and additionally with an equivalent of water to form glycerin ($C_6H_7O_5+HO$).

Other oleaginous substances and other metallic oxides are susceptible of the same combination, and some of them form compounds having the consistence of a plaster; but according to *M. Henry*, of Paris, no oily matter except animal fat can properly be substituted for olive oil, and no metallic oxide, not even one

of the other oxides of lead, for litharge. He ascertained, moreover, that the English litharge is preferable for the formation of lead plaster to the German. From more recent experiments of Soubeiran, it appears that massicot or even minium may be substituted for litharge, and a plaster of good consistence be obtained; but that a much longer time is required for completing the process than when the officinal formula is followed. When minium is used, the necessity for its partial deoxidation renders a longer continuance of the process necessary than with massicot. According to M. Davallon, Professor in the School of Medicine and Pharmacy at Lyons, it is important that the olive oil employed should be pure; for when adulterated, as it frequently is in commerce, it yields an imperfect product. Mr. N. S. Thomas prepared a good plaster by substituting lard for olive oil, in the proportion of eight pounds of lard to five of litharge. (*Am. Journ. of Pharm.*, xix. 175.)

Lead plaster has also been prepared by double decomposition between soap and acetate or subacetate of lead; but the results have not been so advantageous as to lead to the general adoption of this process. For particular information on the subject the reader is referred to the *American Journal of Pharmacy* (ix. 127), and to the *Journal de Pharmacie* (xxiii. 163 and 322).

Preparation. The vessel in which the lead plaster is prepared, should be of such a size that the materials will not occupy more than two-thirds of its capacity. The oil should be first introduced, and the litharge then sprinkled in by means of a sieve, the mixture being constantly stirred with a spatula. The particles of the oxide are thus prevented from coalescing in small masses, which the oil would not easily penetrate, and which would therefore delay the process. While the water exerts an important chemical agency in the changes which occur, it is also useful by preventing too high a temperature, which would decompose the oil and cause the reduction of the metal. The waste must, therefore, be supplied by fresh additions as directed in the process; and the water added for this purpose should be previously heated, as otherwise it would not only delay the operation, but by producing explosion might endanger the operator. During the continuance of the boiling, the materials should be constantly stirred, and the spatula should be repeatedly passed along the bottom of the vessel, from side to side, so as to prevent any of the oxide, which is disposed by its greater density to sink to the bottom, from remaining in that situation. The materials swell up considerably in consequence partly of the vaporization of the water, partly of the escape of carbonic acid gas, which is liberated by the oily acids from some carbonate of lead usually contained in the litharge. The process should not be continued longer than is sufficient to produce complete union of the ingredients, and this may be known by the colour and consistence of the mass. The colour of the litharge gradually becomes paler, and at length almost white when the plaster is fully formed. The consistence increases with the progress of the boiling, and is sufficiently thick, when a portion of the plaster, taken out and allowed to cool upon the end of a spatula, or thrown into cold water, becomes solid, without adhering in this state to the fingers. The portion thus solidified should not present, when broken, any red points, which would indicate the presence of a portion of uncombined litharge. When the plaster is formed, it should be removed from the fire, and after a short time cold water should be poured upon it. Portions should then be detached from the mass, and, having been well kneaded under water, in order to separate the viscid solution of glycerin contained in the interior, should be formed into cylindrical rolls, and wrapped in paper. Such at least has been the course of proceeding usually recommended. But M. Davallon maintains that the presence of glycerin in the plaster is useful by keeping it in a plastic state, and that washing and kneading are injurious, the former by removing the glycerin, the latter by introducing

particles of air and moisture into the mass, which is thus rendered more disposed to rancidity. (*Am. Journ. of Pharm.*, xv. 274, from *Journ. de Chim. Méd.*) By employing steam heat in the preparation of this plaster the risk of burning it is avoided. For a good arrangement for this purpose see *Mohr and Redwood's Pharmacy*, edited by Prof. Procter, p. 420.

Medical Properties and Uses. This plaster, which has long been known under the name of *diachylon*, is used as an application to excoriated surfaces, and to slight wounds, which it serves to protect from the action of the air. It may also be beneficial by the sedative influence of the lead which enters into its composition. A case is on record in which lead colic resulted from its long-continued application to a large ulcer of the leg. (*Am. Journ. of Med. Sci.*, xxiii. 246.) Its chief use is in the preparation of other plasters.* While in its yet incomplete state, it is used in the preparation of glycerin. (See *Glycerina.*)

Off. Prep. Emplastrum Assafœtidæ; Emp. Ferri; Emp. Galbani Compositum; Emp. Gummosum; Emp. Hydrargyri; Emp. Opii; Emp. Resinæ; Emp. Saponis; Unguentum Plumbi Compositum. W.

EMPLASTRUM POTASSII IODIDI. *Lond. Plaster of Iodide of Potassium.*

"Take of Iodide of Potassium *an ounce;* prepared Thus [frankincense] *six ounces;* Wax *six drachms;* Olive Oil *two fluidrachms.* To the Thus and Wax melted together add the Iodide previously rubbed with the Oil, and stir constantly till they cool. This plaster is to be spread rather on linen than leather." *Lond.*

This plaster may be employed for the resolution of indolent tumours, and for the other purposes for which the preparations of iodine are used externally. (See *Potassii Iodidum.*) W.

EMPLASTRUM RESINÆ. *U. S., Lond., Dub.* EMPLASTRUM RESINOSUM. *Ed.* EMPLASTRUM ADHÆSIVUM. *Resin Plaster. Adhesive Plaster.*

"Take of Resin, in powder, *half a pound;* Lead Plaster *three pounds.* To the Lead Plaster melted over a gentle fire add the Resin, and mix them." *U. S.*

The *London* process differs only in melting the resin before adding it. The *Edinburgh College* orders *five ounces* of the lead plaster, and *one* of resin. The *Dublin* melts *two pounds* of litharge plaster over a gentle fire, then adds *four ounces* of powdered resin, and *two ounces* of powdered castile soap, and mixes them intimately, employing the avoirdupois weights in the process.

This preparation differs from the lead plaster in being more adhesive and somewhat more stimulating. It is the common adhesive plaster of the shops, and is much employed for retaining the sides of wounds in contact, and for dressing ulcers according to the method of Baynton, by which the edges are drawn towards each other, and a firm support is given to the granulations. As prepared by the Dublin College it contains soap, which gives it greater pliability, and renders it less liable to crack in cold weather, without impairing its adhe-

* *A plaster of carbonate of lead* was originally introduced into our Pharmacopœia as a substitute for *Mahy's plaster*, so much employed in some parts of the United States; but was omitted in the edition of 1840. It is a good application to surfaces inflamed or excoriated by friction; and may be resorted to with advantage in those troublesome cases of cutaneous irritation, and even ulceration, occurring upon the back and hips during long-continued confinement to one position. We give the process as contained in the Pharmacopœia of 1830. "Take of Carbonate of Lead *a pound;* Olive Oil *two pints;* Yellow Wax *four ounces;* Lead Plaster *a pound and a half;* Florentine Orris, in powder, *nine ounces.* Boil together the Oil and Carbonate of Lead, adding a little water, and constantly stirring, till they are thoroughly incorporated; then add the Wax and Plaster, and, when these are melted, sprinkle in the Orris, and mix the whole together." By this process, a good plaster may be prepared, rather too soft, perhaps, at first, but soon acquiring the proper consistence.

siveness. As thus prepared, it is equivalent to the *Emplastrum Saponis Compositum vel adhærens* of the old Dublin Pharmacopœia. It is usually spread upon muslin; and the spreading is best accomplished, on a large scale, by means of a machine, as described in the general observations upon plasters. It is kept in the shops ready spread; but, as the plaster becomes less adhesive by long exposure to the air, the supply should be frequently renewed. When the skin is very delicate, it occasionally excites some irritation, and under these circumstances a plaster may be substituted, containing a smaller proportion of resin. That originally employed by Baynton contained only six drachms of resin to the pound of lead plaster.

In order to render the plaster more adhesive, and less brittle in cold weather, it is customary with many apothecaries to employ a considerable proportion of Burgundy pitch or turpentine in its preparation; but these additions are objectionable, as they greatly increase the liability of the plaster to irritate the skin, and thus materially interfere with the purposes for which the preparation was chiefly intended.*

Off. Prep. Emplastrum Belladonnæ; Emplastrum Opii. W.

EMPLASTRUM SAPONIS. *U. S., Lond., Ed., Dub. Soap Plaster.*

"Take of Soap, sliced, *four ounces;* Lead Plaster *three pounds.* Rub the Soap with sufficient water to bring it to a semi-fluid state; then mix it with the Plaster previously melted, and boil to the proper consistence." *U. S.*

"Take of Soap, sliced, *half a pound;* Lead Plaster *three pounds;* Resin *an ounce.* To the Plaster melted by a slow fire add the Soap and Resin previously liquefied; then evaporate the whole, constantly stirring, to the proper consistence." *Lond.*

"Take of Litharge Plaster [Lead Plaster] *four ounces;* Gum Plaster *two ounces;* Castile Soap, in shavings, *one ounce.* Melt the Plasters together with a moderate heat, add the Soap, and boil for a little." *Ed.*

"Take of Castile Soap, in powder, *four ounces;* Litharge Plaster [Lead Plaster] *two pounds and a half.* To the Plaster previously melted over a gentle fire, add the Soap, and heat them together until they are thoroughly incorporated." *Dub.* The avoirdupois weights are used in this process.

The present U. S. process is an improvement upon that of the former edition of the Pharmacopœia. The proportion of soap in the old process was so large as to render the plaster friable. It has been diminished from six to four ounces. Besides, by the present mode of proceeding, it is more thoroughly incorporated with the plaster. The same end of greater plasticity is accomplished, in some degree, in the London process by the resin, and in the Edinburgh by the gum plaster.

Soap plaster is considered discutient, and is sometimes used as an application to tumours.

Off. Prep. Emplastrum Belladonnæ. W.

EMPLASTRUM SIMPLEX. *Ed. Simple Plaster.*

"Take of Bees'-wax *three ounces;* Suet and Resin, of each, *two ounces.* Melt them together with a moderate heat, and stir the mixture briskly till it concretes on cooling." *Ed.*

* An adhesive plaster, exempt from oxide of lead, is prepared by Pettenkofer. It consists of calcareous soap incorporated with turpentine and suet, and may be prepared in the following manner. A solution of soap is decomposed by a solution of chloride of calcium. The precipitate, having been expressed and dried, is powdered with half its weight of turpentine dried by heat; and the mixture is melted along with an eighth part of suet, in boiling water. The mixture is boiled until the mass melts into a homogeneous fluid, when it is worked by the hand, in the ordinary manner, in cold water. Should portions of the calcareous soap not melt, they should be separated by straining through flannel. (*Journ. de Pharm., 3e sér.*, x. 358, from *Repertorium für die Pharm.*, xlii. 40.)

This plaster was originally intended for dressing blistered surfaces, in order to maintain a moderate discharge, to which purpose it is adapted by the stimulant property of the resin. But its stiffness and adhesiveness render it unpleasant and of difficult management; and it has been entirely superseded by the resin cerate. It is equivalent to the old *Emplastrum Ceræ* of the London College.

W.

ENEMATA.

Clysters.

These can scarcely be considered proper objects for officinal direction; but, having been introduced into the British Pharmacopœias, the plan of this work requires that they should be noticed. They are substances in the liquid form, intended to be thrown up the rectum, with the view either of evacuating the bowels, of producing the peculiar impression of a remedy upon the lower portion of the alimentary canal and neighbouring organs, or of acting on the system generally through the medium of the surface to which they are applied. They are usually employed to assist the action of remedies taken by the mouth, or to supply their place when the stomach rejects them, or is insensible to their impression. Sometimes they are preferably used when the seat of the disorder is in the rectum or its vicinity. As a general rule, three times as much of any remedy is required to produce a given impression by enema, as when taken into the stomach; but this rule should be acted on with caution, as the relative susceptibilities of the stomach and rectum are not the same in all individuals; and, with regard to all very active remedies, the best plan is to administer less than the stated proportion. Attention should also be paid to the fact, that, by the frequent use of a medicine, the susceptibility of the stomach may be in some measure exhausted, without a proportionate diminution of that of the rectum.

When the object is to evacuate the bowels, the quantity of liquid administered should be considerable. For an adult from ten fluidounces to a pint; for a child of eight or ten years, half that quantity; for an infant within the year, from one to three fluidounces, are about the proper proportions. Much larger quantities of mild liquids may sometimes be given with safety and advantage; as the bowels will occasionally feel the stimulus of distension, when insensible to irritating impressions.

When the design is to produce the peculiar impression of the remedy upon the neighbouring parts, or on the system, it is usually desirable that the enema should be retained; and the vehicle should therefore be bland, and as small in quantity as is compatible with convenient administration. A solution of starch, flaxseed tea, or other mucilaginous fluid should be selected, and the quantity should seldom exceed two or three fluidounces.

In every case, the patient should be instructed to resist any immediate disposition to discharge the injected fluid; and his efforts to retain it should be assisted, if necessary, by pressure with a warm folded towel upon the fundament. The best instrument for administering enemata is an accurate metallic syringe.

W.

ENEMA ALOËS. *Lond.* *Clyster of Aloes.*

"Take of Aloes *two scruples;* Carbonate of Potassa *fifteen grains;* Decoction of Barley *half a pint* [Imperial measure]. Mix, and rub them together." *Lond.*

This is intended as a formula for the use of aloes in cases of ascarides in the rectum, and of amenorrhœa attended with constipation. W.

ENEMA ASSAFŒTIDÆ. *Lond.* ENEMA FŒTIDUM. *Ed., Dub.* *Clyster of Assafetida.*

"Take of Prepared Assafetida *a drachm;* Decoction of Barley *half a pint*

[Imperial measure]. Rub the Assafetida with the Decoction gradually added, till they are thoroughly mixed." *Lond.*

The *Edinburgh College* prepares this by adding *two drachms* of tincture of assafetida to the cathartic clyster; the *Dublin*, by mixing *two fluidrachms* of the tincture with *twelve fluidounces* of warm water.

This is carminative and antispasmodic as well as laxative. The preparation of the London Pharmacopœia is, we think, the best. The whole quantity directed may be administered at once. W.

ENEMA CATHARTICUM. *Ed., Dub. Cathartic Clyster.*

"Take of Olive Oil *one ounce;* Sulphate of Magnesia *half an ounce;* Sugar *one ounce;* Senna *half an ounce;* Boiling Water *sixteen fluidounces.* Infuse the Senna for an hour in the Water; then dissolve the Salt and Sugar; add the Oil, and mix them by agitation." *Ed.*

"Take of Sulphate of Magnesia *one ounce* [avoirdupois]; Olive Oil *one fluidounce;* Mucilage of Barley *sixteen fluidounces.* Dissolve the Sulphate of Magnesia in the Mucilage, add the Oil, and mix." *Dub.*

The laxative enema most commonly employed in this country, consists of a tablespoonful of common salt, two tablespoonfuls of lard or olive oil, the same quantity of molasses, and a pint of warm water. It has the advantage of consisting of materials which are always at hand in families, is in all respects equal to the Dublin preparation, and, though less active than the Edinburgh, is preferable to it on ordinary occasions.

Off. Prep. Enema Fœtidum. W.

ENEMA COLOCYNTHIDIS. *Lond. Clyster of Colocynth.*

"Take of Extract of Colocynth *half a drachm;* Soft Soap *an ounce;* Water *a pint* [Imperial measure]. Mix, and rub them together." *Lond.*

This may be employed whenever a very powerful purgative impression is required upon the lower bowels, as in obstinate colic and constipation. W.

ENEMA OPII. *Lond.* ENEMA OPII vel ANODYNUM. *Ed. Clyster of Opium.*

"Take of Decoction of Starch *four fluidounces;* Tincture of Opium *thirty minims.* Mix them." *Lond.*

The *Edinburgh College* boils *half a drachm* of starch in *two fluidounces* of water, and, when it is cool enough for use, adds from *thirty minims* to *a fluidrachm* of tincture of opium.

Of these processes that of the London College is preferable, although the quantity of decoction of starch is unnecessarily large. The Edinburgh process is objectionable from its indefiniteness. It must have happened to every one in the habit of prescribing opium in this way, to have seen a much greater effect produced by a certain amount of laudanum injected into the rectum than by one-third of the quantity swallowed. The fluidrachm contains at least one hundred drops of laudanum of the ordinary size, and not less than one hundred and twenty as they are often formed. From twenty to twenty-five drops are usually considered as a medium dose by the mouth; so that sixty drops, equivalent to about thirty minims, are abundantly sufficient by enema. The quantity, therefore, ordered by the London College, and the smallest quantity by the Edinburgh, is the full dose. As the object is that the enema should remain in the rectum, the smaller the quantity of the vehicle the better; and a mucilaginous fluid is preferable to water, as it involves the tincture, and prevents the irritation of the alcohol before the opium begins to take effect. The ordinary anodyne enema, employed in this country, consists of about sixty drops of laudanum and one or two fluidounces of flaxseed tea or solution of starch.

This is an admirable remedy in obstinate vomiting, strangury from blisters, painful affections of the kidneys, bladder, and uterus, and in the tenesmus of dysentery. It may also frequently be employed to produce the effects of opium upon the system, when circumstances prevent the administration of that medicine by the mouth. W.

ENEMA TEREBINTHINÆ. *Lond., Ed., Dub. Clyster of Turpentine.*

"Take of Oil of Turpentine *a fluidounce;* the Yolk of *one* Egg; Decoction of Barley *nineteen fluidounces.* Rub the Oil with the Yolk, and mix the Decoction with them." *Lond.*

The *Edinburgh College* employs the same proportions, but substitutes water for decoction of barley. The *Dublin College* mixes *a fluidounce* of the oil with *sixteen fluidounces* of mucilage of barley. (See *Oleum Terebinthinæ.*) W.

EXTRACTA.

Extracts.

Extracts, as the term is employed in the Pharmacopœias, are solid substances, resulting from the evaporation of the solutions of vegetable principles, obtained either by exposing the vegetable to the action of a solvent, or by expressing its juice in the recent state. The Dublin College formerly made a distinction between those prepared from the infusions, decoctions, or tinctures, and those from the expressed juices of plants, calling the former *Extracta*, the latter *Succi Spissati;* but abandoned it in the last edition of its Pharmacopœia. There is no such essential difference between these two sets of preparations, as to require that they should be separately classed; and something is gained in the simplicity of nomenclature, as well as of arrangement, which results from their union. We shall consider them under the same head, taking care, however, to detail distinctly whatever is peculiar in the mode of preparing each.

The composition of extracts varies with the nature of the vegetable, the character of the solvent, and the mode of preparation. The object is generally to obtain as much of the active principles of the plant, with as little of the inert matter as possible; though sometimes it may be desirable to separate the active ingredients from each other, when their effects upon the system are materially different; and this may be accomplished by employing a menstruum which, while it dissolves one, leaves the other untouched. The proximate principles most commonly present in extracts are gum, sugar, starch, tannin, extractive, colouring matter, salts, and the peculiar principles of plants; to which, when a spirituous solvent is employed, may usually be added resinous substances, fatty matter, and frequently more or less essential oil; gum and starch being excluded when the menstruum is pure alcohol. Of these substances, as well as of others which, being soluble, are sometimes necessarily present in extracts, we have taken occasion to treat under various heads in the Materia Medica. There is one, however, which, from its supposed almost uniform presence in this class of preparations, and from the influence it is thought to exert upon their character, deserves particular consideration in this place. We allude to *extractive*, or, as it is sometimes called, *extractive matter.*

It has long been observed that in most vegetables there is a substance, soluble both in water and alcohol, which, in the preparation of extracts, undergoes chemical change during the process of evaporation, imparting to the liquid, even if originally limpid, first a greenish, then a yellowish-brown, and ultimately a deep-brown colour, and becoming itself insoluble. This substance, originally called *saponaceous matter* by Scheele, afterwards received the more expressive

name of *extractive*, derived from its frequent presence in extracts. Its existence as a distinct principle is denied, or at least doubted by some chemists, who consider the phenomena supposed to result from its presence, as depending upon the mutual reaction of other principles; and, in relation to Peruvian bark, it appears to have been proved that the insoluble matter which forms during its decoction in water is a compound of starch and tannin. A similar compound must also be formed in other cases when these two principles co-exist; but they are not always present in the same vegetable, nor can all the changes which have been attributed to extractive be accounted for by their union, even when they are present; so that, till further light is shed on the subject, it is best to admit the existence of a distinct substance, which, though not the same in all plants, possesses sufficient identity of character to be entitled, like sugar, resin, &c., to a distinctive name. The most interesting property of extractive is its disposition to pass, by the influence of atmospheric air at a high temperature, into an insoluble substance. If a vegetable infusion or decoction be evaporated in the open air to the consistence of an extract, then diluted, filtered, and again evaporated, and the process repeated so long as any insoluble matter is formed, the whole of the extractive will be separated from the liquid, while the other ingredients may remain. If chlorine be passed through an infusion or decoction, a similar precipitate is formed with much greater rapidity. The change is usually ascribed to the absorption of oxygen by the extractive, which has, therefore, been called, in its altered condition, oxidized extractive; but De Saussure ascertained that, though oxygen is absorbed during the process, an equal measure of carbonic acid gas is given out, and the oxygen and hydrogen of the extractive unite to form water in such a manner as to leave the principle richer in carbon than it was originally. The name of oxidized extractive is, therefore, obviously incorrect; and Berzelius proposes to substitute for it that of *apotheme*, synonymous with deposit. According to Berzelius, apotheme is not completely insoluble in water, but imparts a slight colour to that liquid when cold, and is rather more soluble in boiling water, which becomes turbid upon cooling. It is still more soluble in alcohol, and is freely dissolved by solutions of the alkalies and alkaline carbonates, from which it is precipitated by acids. It has a great tendency, when precipitated from solutions, to unite with other principles, and to carry them along with it; thus acquiring properties somewhat different, according to the source from which it is obtained. In this way, also, even when the extractive of a plant is itself medicinally inert, its conversion into apotheme may be injurious by causing a precipitation of a portion of the active principle; and, in practical pharmaceutic operations, this change should always, if possible, be avoided. With these preliminary views, we shall proceed to the consideration of the practical rules necessary to be observed in the preparation of extracts. We shall treat of the subject under the several heads of, 1. the extraction of the soluble principles from the plant; 2. the method of conducting the evaporation; 3. the proper condition of extracts, the changes they are liable to undergo, and the best method of preserving them; and 4. the general directions of the several Pharmacopœias in relation to them.

1. *Extraction of the Soluble Principles.*

There are two distinct modes of obtaining, in a liquid state, the principles which we wish to extract; 1. by expression alone; 2. by the agency of a solvent, with or without expression.

1. *By Expression.* This method is applicable to recent vegetables. All plants cannot be advantageously treated in this way, as many have too little juice to afford an appreciable quantity upon pressure, and of the succulent a considerable

portion do not yield all their active principles with their juice. Succulent fruits, and various acrid and narcotic plants, are proper subjects of this treatment. The plants should be operated upon, if possible, immediately after collection. Mr. Battley, of London, recommends that, if not entirely fresh, they should be revived by the immersion of the stalks in water for twelve or eighteen hours, and those only used which recover their freshness by this management. They should then be cut into pieces, and bruised in a stone mortar till brought to a pulpy consistence. When the plant is not very succulent, it is necessary to add a little water during this part of the process, in order to dilute the juice. After sufficient contusion, the pulp is introduced into a linen or canvas bag, and the liquid parts expressed. Mr. Brande states that light pressure only should be employed; as the extract is thus procured greener, of a less glutinous or viscid consistence, and, in his opinion, more active than when considerable force is used in the expression. (*Manual of Pharmacy.*) The juice thus obtained is opaque and usually green, in consequence of the presence of green wax or chlorophylle, and of a portion of the undissolved vegetable fibre in minute division. By heating the juice to about 160°, the albumen contained in it coagulates, and, involving the chlorophylle and vegetable fibre, forms a greenish precipitate. If the liquid be now filtered, it becomes limpid and nearly colourless, and is prepared for evaporation. The clarification, however, is not absolutely necessary, and is generally neglected. Sometimes the precipitate carries with it a considerable portion of the active principle; in which case it should be subsequently incorporated with the juice, when reduced by evaporation to the consistence of a syrup.

2. *By Solution.* The active principles of dried vegetables can be extracted only by means of a liquid solvent. The menstruum usually employed is either water or alcohol, or a mixture of the two. Water, on account of its cheapness, is always preferred, when circumstances do not strongly call for the use of alcohol. It has the advantage, moreover, that it may be assisted in its action, if necessary, by a higher degree of heat than the latter. Pump water is often unfit for the purpose, in consequence of the quantity of its saline matter, which, in some instances, may exert an unfavourable influence on the active principle, and must always be left in the extract. Rain, river, or distilled water should be preferred. Alcohol is employed when the principles to be extracted are insoluble, or but slightly soluble in water, as in the case of the resins; when it is desirable to avoid in the extract inert substances, such as gum and starch, which are dissolved by water and not by alcohol; when the heat required to evaporate the aqueous solution would dissipate or decompose the active ingredients of the plant, as the volatile oils and the active principle of sarsaparilla; when the reaction of the water itself upon the vegetable principles is injurious; and, finally, when the nature of the substance to be exhausted requires so long a maceration in water as to endanger spontaneous decomposition. The watery solution requires to be soon evaporated, as this fluid rather promotes than counteracts chemical changes; while an alcoholic tincture may be preserved unaltered for an indefinite period. An addition of alcohol to water is sufficient to answer some of the purposes for which the former is preferable; and the employment of both fluids is essential, when the virtues of the plant reside in two or more principles, all of which are not soluble in either of these menstrua. In this case it is usually better to submit the vegetable to the action of the two fluids successively, than to both united. Extracts obtained by the agency of water, are called *watery* or *aqueous extracts*, those by means of alcohol, undiluted or diluted, *alcoholic* or *spirituous extracts*.

The method of preparing the solution is not a matter of indifference. The vegetable should be thoroughly bruised, or reduced to a coarse powder, so as to allow the access of the solvent to all its parts, and yet not so finely pulverized as to prevent a ready precipitation of the undissolved and inactive portion.

When water is employed, it has been customary to boil the medicine for a considerable time, and, if the first portion of liquid does not completely exhaust it, to repeat the operation with successive portions, till the whole of the active matter is extracted. This may be known by the sensible properties of the liquid, and by its influence upon reagents. But the boiling temperature produces the decomposition of many vegetable principles, or at least so modifies them as to render them inert; and the extracts prepared by decoction are usually less efficient than those prepared with a less degree of heat. From numerous experiments upon extracts, Orfila concluded that their virtues were less in proportion to the heat employed. It has, therefore, been recommended to substitute for decoction the process of maceration, digestion, or hot infusion; in the first of which the liquid acts without heat, in the second is assisted by a moderately increased temperature sustained for a considerable time, and in the third is poured boiling hot upon the vegetable matter, and allowed to stand for a short period in a covered vessel. When the active principles are readily soluble in cold water, *maceration* is often preferable to the other modes, as starch, which is inert, is thus left behind; but in many instances the preparation would spoil before the extraction would be completed. By *digestion*, though the solvent power of water is moderately increased, the advantage is often more than counterbalanced by the increased disposition to spontaneous decomposition. *Hot infusion*, therefore, is to be preferred where the vegetable does not readily yield its virtues to cold water. It has the advantage, moreover, in the case of albuminous substances, that the albumen is coagulated, and thus prevented from increasing the bulk of the extract, without any addition to its virtues. A convenient mode of performing this process, is to introduce the solid material into a vessel with an opening near the bottom temporarily closed, or into a funnel with its mouth loosely stopped, then to pour on the boiling water, and, having allowed it to remain a sufficient length of time, to draw it off through the opening. This operation may be repeated till the water comes away without any obvious impregnation. It is always desirable to obtain the solution in the first place as concentrated as possible, so as to prevent the necessity of long continued evaporation, which injures the extract. It is better, therefore, to incur the risk, both where decoction and infusion are employed, of leaving a portion of the active matter behind, than to obtain a very weak solution. When successive portions of water are employed, those which are least impregnated should be brought by evaporation to the strength of that first obtained before being mixed with it, as the latter thus escapes exposure to unnecessary heat.

When alcohol is employed as a menstruum, the vegetable should be macerated in it for one or two weeks, and care should be taken that the tincture be as nearly saturated as possible. The extraction may be hastened by substituting digestion for maceration; as the moderate heat employed, while it facilitates the action of the alcohol, has in this case no effect in promoting decomposition, and the influence of the atmospheric air may be excluded by performing the process in close vessels. When alcohol and water are both used, it is best, as a general rule, to exhaust the vegetable with each separately, as the two menstrua require different modes of treatment. In whichever of these modes the extraction is effected, it requires the assistance of occasional agitation; and, when the vegetable matter is very porous, and absorbs large quantities of the solvent, expression must be resorted to.

Acetic acid has been introduced into use as a menstruum in the preparation of extracts. It is supposed to be a better solvent of the active principles of certain substances than either water or alcohol alone. According to Girolamo Ferrari, the acrid narcotics, such as aconite, hemlock, hyoscyamus, and stramonium, yield much stronger extracts with distilled vinegar than with water, and

still stronger to alcohol to which strong acetic acid has been added. (*Journ. de Pharm. 3e sér.*, i. 239.) This acid is used in the preparation of the acetic extract of colchicum.

Ether is now also used to a considerable extent in the preparation of certain extracts. Having the property of dissolving volatile oil and resin, and of evaporating at a temperature insufficient to volatilize the oil, it is admirably adapted for the preparation of extracts from those substances the virtues of which reside in the two principles referred to. An ethereal tincture is first prepared by the process of percolation or displacement, and the ether is then either allowed to escape by spontaneous evaporation, or is distilled off at a very moderate heat. The oleo-resinous extracts thus obtained are usually of a thick fluid or semi-fluid consistence. For more precise information as to the mode of preparing them, the reader is referred to a paper by Prof. Procter, in the *Amer. Journ. of Pharm.* (xxi. 114). Several of them are now ranked among the officinal preparations, in the U. S. Pharmacopœia, under the title of *Fluid Extracts.*

The process of percolation or displacement has within a few years been very advantageously applied to the preparation of extracts, both with water and spirituous menstrua. It has the following great advantages; 1. that it enables the soluble principles to be sufficiently extracted by cold water, thereby avoiding the injury resulting from heat in decoction and hot infusion; 2. that it effects the extraction much more quickly than can be done by maceration, thereby not only saving time, but also obviating the risk of spontaneous decomposition; and 3. that it affords the opportunity of obtaining highly concentrated solutions, thus diminishing all the injurious effects of the subsequent evaporation. While thus advantageous, it is less liable in this particular case than in others to the objection of yielding imperfect results if not well performed; for, though an inexpert or careless operator may incur loss by an incomplete exhaustion of the substance acted on, and the extract may be deficient in quantity, it may still be of the intended strength and quality, which is not the case with infusions or tinctures unskilfully prepared upon this plan. For an account of the mode of operating in the process of displacement, and of the instruments used, the reader is referred to pages 782 and 789.

Some prefer the mode of expression to that of displacement. This also is applicable both to watery and alcoholic menstrua. The substance to be acted upon is mixed with the menstruum, cold or hot according to circumstances; and the mixture is allowed to stand from twelve to twenty-four hours. The liquid part is then filtered off, and the remainder submitted to strong pressure, in a linen bag, by means of a common screw press, or other convenient instrument. Another portion of the menstruum may then be added, and pressure again applied; and, if the substance is not sufficiently exhausted, the same operation may be performed a third time. Frequently only a single expression is required, and very seldom a third. The quantity of menstruum added must vary with the solubility of the principles to be extracted. According to Mohr, the method of expression has the advantages over that of displacement, that it yields solutions of more uniform concentration, that it does not require the material to be so carefully powdered, or otherwise so skilfully managed in order to insure favourable results, and finally that it occupies less time.

2. *Mode of conducting the Evaporation.*

In evaporating the solutions obtained in the modes above described, attention should always be paid to the fact, that the extractive matter is constantly becoming insoluble at high temperatures with the access of air, and that other chemical changes are going on, sometimes not less injurious than this, while the volatile principles are expelled with the vapour. The operator should,

therefore, observe two rules; 1. to conduct the evaporation at as low a temperature as is consistent with other objects; 2. to exclude atmospheric air as much as possible, and, when this cannot be accomplished, to expose the liquid the shortest possible time to its action. According to Berzelius, the injurious influence of atmospheric air is much greater at the boiling point of water than at a less heat, even allowing for the longer exposure in the latter case; and, therefore, a slow evaporation at a moderate heat is preferable to the more rapid effects of ebullition. Bearing these principles in mind, we shall proceed to examine the different modes in practice. First, however, it is proper to observe that decoctions generally let fall upon cooling a portion of insoluble matter; and it is a question whether this should be rejected, or retained so as to form a part of the extract. Though it is undoubtedly in many instances inert, as in that of the insoluble tannate of starch formed during the decoction of certain vegetable substances, yet, as it frequently also contains a portion of the active principle which a boiling saturated solution necessarily deposits on cooling, and, as it is difficult to decide with certainty when it is active and when otherwise, the safest plan, as a general rule, is to allow it to remain.

The method of evaporation usually resorted to in the case of the aqueous solutions is rapid boiling over a fire. The more quickly the process is conducted the better, provided the liquid is to be brought to the boiling point; for the temperature cannot exceed this, and the length of exposure is diminished. But, even where this method is employed, it should not be continued till the completion of the evaporation; for, when most of the water has escaped, the temperature can no longer be kept down to the boiling point, and the extract is burnt. The caution, therefore, should always be observed of removing the preparation from the fire, before it has attained the consistence of thick syrup, and completing the evaporation either by means of a water-bath, or in shallow vessels at a moderate heat. When large quantities of liquid are to be evaporated, it is best to divide them into portions, and evaporate each separately; for, as each portion requires less time for evaporation than the whole, it will thus be a shorter time exposed to heat. (*Mohr.*) But the mode of evaporation by boiling is always more or less objectionable, and should be employed only in cases where the principles of the plant are so fixed and unchangeable as to authorize their extraction by decoction.

Evaporation by means of the water-bath, from the commencement of the process, is safer than the plan just mentioned, as it obviates all danger of burning the extract; but, as the heat is not supplied directly from the fire, the volatilization of the water cannot go on so rapidly, and the temperature being the same, or very nearly so, when the water-bath is kept boiling, there is greater risk of injurious action from the air. The liquid should be stirred during the process. The use of the vapour-bath, as suggested by M. Henry, is perhaps preferable; as it requires a smaller consumption of fuel, and the heat imparted to the liquid, while sufficient to evaporate it, is less than 212°. We take the following description of the apparatus employed at the Central Pharmacy of Paris, from M. Chevallier's highly useful Manual. It consists of a covered boiler, containing water, the vapour of which is conducted through a pipe into evaporating vessels, communicating with each other by means of metallic tubes. These vessels have the form of an ordinary copper basin, over the top of which is soldered a shallow tin capsule, intended to contain the liquor to be evaporated. The vapour from the boiler circulates through these vessels, and the water into which it condenses is allowed to escape through a stop-cock attached to the bottom of each vessel. From the last one of the series a tube passes into a vessel of water, so as to afford a slight pressure against the escape of any excess of vapour. The liquid to be evaporated is first distributed in two or three capsules, but when con-

siderably concentrated is transferred to a single one, where it is stirred towards the close of the process to hasten the evaporation. The heat applied to the liquid, if there are four vessels, is in that nearest the boiler about 198° F., in the fourth or most remote, about 135°. An incidental advantage of this apparatus is, that it affords a large supply of distilled water.

A good plan of evaporation, though slow, is to place the liquid in a broad shallow vessel, exposed in a stove or drying room to a temperature of about 100°, or a little higher, taking care that the air have free access in order to facilitate the evaporation. This mode is particularly applicable to those cases in which maceration or infusion is preferred to decoction for extracting the active principles. Berzelius says that we may thus usually obtain the extract in the form of a yellowish transparent mass, while those prepared in the ordinary way are almost black, and are opaque even in very thin layers. Even when the liquid is boiled at first, the process may often be advantageously completed in this manner. It has been proposed to effect the evaporation at the common temperature, by directing a strong current of air, by means of a pair of smith's bellows, over the surface of the liquid; and in reference to substances which are injured by heat and not by atmospheric air, the plan will be found useful.

Plans have been proposed and carried into execution for performing evaporation without the admission of atmospheric air. The apparatus for evaporation in vacuo invented by Mr. Barry, and described in the *Lond. Journ. of Science and Arts* (vol. viii. p. 360), is well calculated to meet this object, at the same time that, by removing the atmospheric pressure, it enables the water to rise in vapour more rapidly, and at a comparatively low temperature. The method of Barry consists in distilling the liquid into a large receiver from which the air has been expelled by steam, and in which the vapour is condensed by cold water applied to the surface of the receiver, so as to maintain a partial vacuum. Mr. Redwood has modified this process by keeping an air-pump in action during the evaporation, thus removing not only the air, but the vapour as fast as it forms, and maintaining a more complete vacuum than can be done by the condensation of the vapour alone. (*Journ. de Pharm.*, *3e sér.*, i. 231.) Another method is to place the liquid under an exhausted receiver, together with some concentrated sulphuric acid, or chloride of calcium, which, by its affinity for water, assists the evaporation of the liquid. But, from the expense and trouble of these modes of evaporation, they are not calculated for general use. Dr. Christison recommends as probably the most perfect and convenient method, especially with watery infusions and decoctions, to evaporate the fluid in a vacuum to the consistence of syrup, and then to complete the process in shallow vessels, exposed to a current of air without heat.*

A convenient plan of excluding the air, though it does not at the same time meet the object of reducing the requisite degree of heat, is to distil off the water

* Mr. Grandval has described an apparatus, for evaporation in vacuo for the preparation of extracts, in the *Journ. de Pharm. et de Chim.*, xv. 82. Messrs. Tilden & Co., of New York, have recently employed a vacuum apparatus analogous to that used in refining sugar. The vacuum is obtained and continued by the constant action of a powerful steam driven pump. Their apparatus includes two evaporating pans; one large, having a capacity of several hundred gallons, used to concentrate the solutions for extracts to a syrupy consistence; the other, holding about fifty gallons, in which the evaporation is finished. The latter is furnished with an opening of such size as to permit the operator to remove the residual extract. The temperature during the evaporation is from 120° to 140° F., and is derived from steam pipes, placed within the boiler in the large evaporating pan, and a steam jacket beneath the smaller one. Very fine extracts are prepared in this way. In the *Journ. de Pharm.* (*3e sér.*, xxiii. 1), MM. Soubeiran and Gobley have particularly described and figured an apparatus, founded upon that of M. Grandval, but modified so as to be adapted to operations on a small scale, and to be within the reach of apothecaries who may desire to prepare their own extracts.—*Note to the ninth and tenth editions.*

in close vessels. Berzelius says that this is the best mode of concentration next to that *in vacuo*. Care, however, must be taken that the fire be not too long applied, lest the extract should be burnt. The process should, therefore, be completed by means of the water-bath.

In the concentration of alcoholic solutions, distillation should always be performed; as not only is the atmospheric air thus excluded, but the alcohol is recovered, if not absolutely pure, certainly fit for the purpose to which it was originally applied. Here also the water-bath should be employed, to obviate any possible risk of injury from the fire. When the decoction or infusion, and tincture of the same vegetable have been made separately, they should be separately evaporated to the consistence of syrup, and then mixed together, while they are of such a consistence as to incorporate without difficulty. The object of this separate evaporation is, that the spirituous extract may not be exposed to the degree of heat, or lengthened action of the air, which is necessary in the ordinary mode of concentrating the infusion or decoction.

In every instance, care should be taken to prevent any portion of the extract from becoming dry and hard on the sides of the evaporating vessel, as in this state it will not readily incorporate with the remaining mass. The heat, therefore, should be applied to the bottom, and not to the sides of the vessel.

3. *Condition and Preservation of Extracts.*

Extracts are prepared of two different degrees of consistence; soft so that they may be readily made into pills, and hard that they may be pulverized. In astringent extracts, the evaporation should be carried to dryness. Those obtained from the expressed juices of plants are apt to attract moisture from the air, in consequence of the deliquescent nature of the salts existing in the juice. They are thus rendered softer, and more liable to become mouldy upon the surface. Others, especially such as contain much chlorophylle, harden by time, in consequence of the escape of their moisture; and it not unfrequently happens that small crystals of saline matter are formed in their substance. Most extracts, especially those containing azotized principles, are capable, when left to themselves, of producing nitrates. The air, moreover, exercises an unfavourable chemical influence over the softer extracts, which are enfeebled, and ultimately become nearly inert, by the same changes which they undergo more rapidly in the liquid state at an elevated temperature. If an extract be dissolved in water, and the liquid be saturated with common salt, or any other very soluble salt of difficult decomposition, the greater part of it is precipitated, in consequence of the insolubility of this class of substances in saline solutions. The precipitate may be again dissolved in pure water.

Extracts, in order that they may keep well, should be placed in glazed earthenware, glass, or porcelain jars, and completely protected from the access of the air. This may be effected by covering their surface with a layer of melted wax, or with a piece of paper moistened with strong spirit, then closing the mouth of the vessel with a cork, spreading wax or rosin over this, and covering the whole with leather, or a piece of bladder. (*Duncan.*) The dry extracts, being less liable to be affected by atmospheric oxygen, do not require so much care. The application of alcohol to the surface has a tendency to prevent mouldiness. A method of protecting extracts from the action of the air frequently resorted to, is to cover them closely with oiled bladder; but this, though better than to leave them uncovered, is not entirely effectual. Should the extract become too moist, it may be dried by means of a water-bath; should it, on the contrary, be too dry, the proper consistence may be restored by softening it in the same manner, and incorporating with it a little distilled water. (*Chevallier.*)

Some extracts when powdered have a tendency to cohere again. According to Geiseler, this may be obviated by the addition of sugar of milk or powdered liquorice-root; two or three parts of the former, and one part of the latter to one of the extract being sufficient for the purpose. (*Pharm. Cent. Blatt*, A. D. 1850, p. 238.) Mohr recommends the following plan of drying and preserving extracts. Take equal parts of powdered liquorice-root and of the extract, rub them well together in a mortar, put the resulting paste into an earthen vessel with a flat bottom, place this in another of iron, a little deeper, containing chloride of calcium thoroughly dried by a heat insufficient to melt it; then enclose the whole with a cover fitted to the iron vessel, and allow them to stand for a day or more. When the extract is quite dry, powder it, and mix it with an equal weight of powdered liquorice-root. (*Ibid.* p. 719.)

Extracts from recent plants should be prepared at the season when the plant is medicinally most active; and a good rule is to prepare them once a year.

4. *General Officinal Directions.*

"In the preparation of the Extracts, evaporate, unless otherwise directed, as quickly as possible, in a broad, shallow dish, by means of a water-bath, until they have acquired the consistence proper for forming pills; and towards the end of the process, stir them constantly with a spatula. Sprinkle upon the softer Extracts a small quantity of Alcohol." *U. S.*

The directions of the *London College* are the same as the above, the sprinkling being omitted.

"Extracts are usually prepared by evaporating the expressed juices of plants, or their infusions and decoctions in water, proof spirit, or rectified spirit, at a temperature not exceeding 212° F., by means of a vapour-bath. Most of them, however, may be obtained of greatly superior quality by the process of evaporation in vacuo. And the extracts of expressed juices cannot, perhaps, be better prepared than by spontaneous evaporation in shallow vessels, exposed to a current of air. Extracts should be evaporated to such a consistence as to form a pill-mass when cold." *Ed.* W.

EXTRACTUM ACONITI. *U. S.*, *Lond.*, *Ed.* *Extract of Aconite.*

This is prepared, according to the U. S. Pharmacopœia, from fresh Aconite Leaves in the manner directed for extract of stramonium leaves. (See *Extractum Stramonii Foliorum.*)

"Take of fresh Aconite Leaves *a pound*. Bruise them in a stone mortar; then express the juice, and evaporate it, without straining, to the proper consistence." *Lond.*

"Take of the Leaves of Monkshood, fresh, *any convenient quantity*. Beat them into a pulp; express the juice; subject the residuum to percolation with Rectified Spirit, so long as the Spirit passes materially coloured; unite the expressed juice and the spirituous infusion; filter; distil off the spirit; and evaporate the residuum in the vapour-bath, taking care to remove the vessel from the heat so soon as the due degree of consistence shall be attained." *Ed.*

The U. S. and London processes for this extract are the same; consisting in the evaporation of the expressed juice of the leaves. The reader will find the general officinal directions at the close of our introductory observations in relation to extracts. Among these observations, he will also find rules which may be of practical use in regulating the various steps of the process under consideration.

In relation to the preparation of this extract, as well as of all others derived from the expressed juices of narcotic plants, the following summary of the plan pursued by Mr. Battley, an experienced apothecary of London, may be of service. Having passed the expressed juice through a fine hair sieve, he places it

immediately upon the fire. Before it boils, a quantity of green matter rises to the surface, which in some plants is very abundant. This is removed by a perforated tin dish, and preserved. It ceases to appear soon after the liquid begins to boil. The boiling is continued till rather more than half the fluid has been evaporated, when the decoction is poured into a conical pan and allowed to cool. An abundant dark-green precipitate forms, from which the supernatant liquid is poured off; and this, having been reduced one-half by a second boiling, is again allowed to stand. The precipitate which now falls is less green than the first. The remaining fluid is once more placed over the fire, and allowed to boil till it assumes the consistence of syrup, when it is removed. The matter at first collected by skimming, together with that precipitated, is now incorporated with it, and the whole placed in a metallic pan, and by means of a water-bath evaporated to the consistence of an extract. In the latter part of the process, care is necessary to prevent the extract from hardening on the sides of the vessel, as it thus loses its fine green colour, and becomes proportionably feeble.

The superiority of this plan over a continuous boiling is, that the portions of active matter which are deposited at different stages of the process, are subjected for a shorter time to heat than if allowed to remain in the liquor, and are consequently less deteriorated. The matter which coagulates before the fluid boils is chiefly albumen, embracing portions of chlorophylle and of the undissolved vegetable fibre. It might probably be thrown away without diminishing the virtues of the extract; but as chlorophylle, though itself inactive, has often associated with it a portion of the active principle, it is the most economical plan to incorporate it with the other matters. Mr. Brande states that one cwt. of fresh aconite yields about five pounds of extract. According to Geiger, one pound yields an ounce and a half.

The Edinburgh process, which was adopted from the Prussian Pharmacopœia, first expresses the leaves, then digests the residue in alcohol, and evaporates the two liquids together. This is an improvement on the other process; as the residue of the leaves after the expression of the juice is still very acrid. But the evaporation of the expressed juice and that of the tincture should be carried on separately to the consistence of a syrup; since, by the present plan, the active matter of both liquids is exposed to heat during the time necessary for the evaporation of the whole.

When properly prepared by means of a water-bath, according to the U. S. and London process, which is that of Störck, this extract has a yellowish-brown colour, with a disagreeable narcotic odour, and the acrid taste of the plant. Prepared according to the Edinburgh process, it is said to be more acrid and more active as a medicine. The extract of aconite may be given in the dose of one or two grains, night and morning, to be gradually increased till the system is affected. Twenty grains or more have been given in the course of a day. Dr. Turnbull states that he has tried several extracts of aconite made by evaporating the expressed juice, and found them almost inert. W.

EXTRACTUM ACONITI ALCOHOLICUM. *U.S.* *Alcoholic Extract of Aconite.*

"Take of Aconite Leaves, in coarse powder, *a pound;* Diluted Alcohol *four pints.* Moisten the powder with half a pint of the Diluted Alcohol, and, having allowed the mixture to stand for twenty-four hours, transfer it to a percolator, and add gradually the remainder of the Diluted Alcohol. When the last portion of this has penetrated the powder, pour in sufficient water from time to time to keep the mass covered. Cease to filter when the liquid which passes begins to produce a precipitate, as it falls, in that which has already passed. Distil off the Alcohol from the filtered liquor, and evaporate the residue to the proper consistence." *U. S.*

This is essentially the process of the French Codex. The water added is merely intended to expel that portion of the spirituous solution remaining in the aconite; and the filtration is directed to cease when a precipitate begins to appear, because this is an indication that the water is passing. It is important that the heat employed in the evaporation should not be greater than that produced by a vapour-bath, as otherwise decomposition will be apt to ensue. If made from recently dried leaves, which have not yet been impaired by time, this is a good preparation of aconite, and is believed to be more powerful, and to keep better, than the inspissated juice. The dose is half a grain or a grain, to be gradually increased if necessary.

An alcoholic extract prepared from the root is stronger, and may be given in the dose of one-sixth or one-quarter of a grain three times a day, to be gradually increased until its effects are experienced.* W.

EXTRACTUM ALOËS. *Lond.* EXTRACTUM ALOËS AQUOSUM. *Dub.* *Extract of Aloes.*

"Take of Socotrine Aloes *fifteen ounces;* Boiling Distilled Water *a gallon* [Imperial measure]. Macerate for three days with a gentle heat; then strain the liquor, and set it by that the dregs may subside. Pour off the clear liquor, and evaporate it to a proper consistence." *Lond.*

"Take of Hepatic Aloes, in coarse powder, *four ounces* [avoirdupois]; Water *two pints* [Imp. meas.]. Boil the Aloes until it is dissolved; when the solution is cold and the dregs have subsided, pour off the clear liquid, and evaporate it to a proper consistence." *Dub.*

Off. Prep. Decoctum Aloës Compositum; Pilula Colocynthidis Composita.

EXTRACTUM ALOËS BARBADENSIS. *Lond.* *Extract of Barbadoes Aloes.*

"Prepare this in the manner directed for Extract of Aloes." *Lond.*

The object of these processes is to separate from aloes the resinoid matter, the *apotheme* of Berzelius, which is supposed to irritate the bowels, without possessing purgative properties; but the truth appears to be, that, when deprived of a small proportion of adhering extractive, this matter is quite inert. It cannot, therefore, injuriously affect the virtues of the medicine; and, as it exists in comparatively small proportion, and during the process a part of the extractive becomes insoluble, the preparation may be considered as at best unnecessary. The dose of the purified aloes is from five to fifteen grains.

Off. Prep. Pilula Aloës cum Sapone. W.

EXTRACTUM ANTHEMIDIS. *Ed.* *Extract of Chamomile.*

"Take of Chamomile [dried flowers] *a pound.* Boil it with *a gallon* [Imperial measure] of Water down to four pints; filter the liquor hot; evaporate in the vapour-bath to the proper consistence." *Ed.*

According to Mr. Brande, one cwt. of dried chamomile flowers affords upon an average 48 pounds of extract.

This extract has a deep-brown colour, and the bitter taste of chamomile, but

* *Plaster of Aconite.*—It is often desirable to employ aconite externally in the form of a plaster, and for this purpose the alcoholic extract of the root may be advantageously resorted to. Professor Procter prepares such a plaster by the following process. Mix four ounces of the coarsely powdered root with six fluidounces of alcohol (sp. gr. 0·835), macerate for 24 hours, then submit the mixture to percolation with alcohol, so as to obtain a pint of tincture. From this distil off three-fourths of the alcohol, and evaporate the residue by a water-bath to a syrupy consistence. While it is still hot, add three ounces and a half of adhesive plaster, previously melted, and stir the mixture constantly till it cools. About four ounces of plaster are thus obtained. (*Am. Journ. of Pharm.* xxv. 202.) —*Note to the tenth edition.*

is wholly destitute of aroma; the volatile oil having been entirely driven off during the process. It does not, therefore, possess the peculiar virtues of the flowers; but is simply a mild bitter, which may sometimes be advantageously combined with laxatives and mineral tonics in debilitated states of the digestive organs. All the effects of the flowers may be obtained from it by adding a little of the oil of chamomile. It is most used, however, as a vehicle for other tonics in the pilular form. The dose is from ten to twenty grains. An extract may be prepared, having the peculiar flavour as well as bitterness of chamomile, by macerating the flowers in water, and evaporating the infusion in vacuo. W.

EXTRACTUM BELLADONNÆ. *U. S., Lond., Ed., Dub. Extract of Belladonna.*

This is prepared from fresh Belladonna (leaves) in the manner directed by the *U. S. Pharmacopœia* for extract of stramonium leaves (see *Extractum Stramonii Foliorum*); and by the *London* for extract of aconite (see *Extractum Aconiti*).

"Take of Belladonna, fresh, *any convenient quantity*. Bruise it in a marble mortar into a uniform pulp; express the juice; moisten the residuum with water, and express again. Unite the expressed fluids, filter them, and evaporate the filtered liquid in the vapour-bath to the consistence of firm extract, stirring constantly towards the close." *Ed.*

"Take of fresh Belladonna Leaves, collected when the plant begins to flower, *any convenient quantity*. Crush them in a mortar, express the juice, and allow it to stand for twenty-four hours. Pour off the clear liquor, and set it aside for subsequent use; and having placed the sediment on a calico filter, wash it with an equal bulk of distilled water, and mix the washings with the decanted liquors. When, by the application of a water heat, coagulation has occurred, skim off the coagulated matter, filter the hot liquid through flannel, mix in now the washed sediment, and evaporate to the consistence of a firm extract, by a steam or water bath, constantly stirring, particularly towards the close of the evaporation." *Dub.*

From the experiments of MM. Solon and Soubeiran, it appears that, in relation to this extract, the insoluble matter separated from the expressed juice by filtering, and that coagulated by heat, are nearly if not quite inert; so that advantage results from clarifying the juice by these means before evaporating it. Mr. Brande states that one cwt. of fresh belladonna yields from 4 to 6 pounds of extract. According to M. Recluz, nearly ten parts may be obtained from one hundred. The extract employed in this country is brought chiefly from England; but Mr. Alfred Jones has found that it may be prepared of equally good quality from the plant grown in the United States. (*Am. Journ. of Pharm.*, xxiv. 108.) It has usually a dark-brown colour, a slightly narcotic not unpleasant odour, a bitterish taste, and a soft consistence which it long retains. Asparagin has been found in this extract. (*Journ. de Pharm.*, xxi. 178.)

Its medical properties and uses have been detailed under the head of Belladonna. A few words in relation to its mode of application may be proper here. For the dilatation of the pupil, it is either mixed with water to the consistence of cream and rubbed on the brow and eyelids, or dissolved in water and dropped into the eye. In rigidity of the os uteri, it is applied at intervals to the neck of the uterus, mixed with simple ointment in the proportion of two drachms to an ounce; but care must be taken not too powerfully to affect the system; and the preparation, therefore, should be used in a small quantity at first. In irritability of the bladder, chordee, spasm of the urethra, and painful constriction of the rectum, it may either be rubbed in the form of ointment upon the perineum, along the urethra, &c., or may be used in the form of enema; but care is requisite not to introduce it too freely into the bowel. It is sometimes smeared upon the

bougie, mixed with oil, in the treatment of stricture of the urethra. In the form of ointment it has been beneficially employed in phymosis and paraphymosis, and in that of plaster or ointment, in local pains of a neuralgic or rheumatic character. (See *Emplastrum Belladonnæ.*) The dose of the extract is uncertain on account of its variable strength. The best plan is to begin with one-quarter or one-half of a grain, repeated two or three times a day, and gradually to increase the dose till the effects of the medicine are experienced. To a child two years old not more than one-twelfth of a grain should be administered at first.

Off. Prep. Emplastrum Belladonnæ; Unguentum Belladonnæ. W.

EXTRACTUM BELLADONNÆ ALCOHOLICUM. *U. S. Alcoholic Extract of Belladonna.*

This is directed by the U. S. Pharmacopœia to be prepared from Belladonna, in coarse powder, in the same manner as the alcoholic extract of aconite. (See *Extractum Aconiti Alcoholicum.*) It is a good preparation, though less necessary than some other spirituous extracts of the narcotic plants; as the inspissated juice, or common extract of belladonna, can generally be procured of good quality. It is one of the officinals of the French Codex. The dose to begin with is half a grain. W.

EXTRACTUM CINCHONÆ FLAVÆ. *U. S.* EXTRACTUM CINCHONÆ. *Lond., Ed. Extract of Yellow Bark.*

"Take of Yellow Bark, in coarse powder, *a pound;* Alcohol *four pints;* Water *a sufficient quantity.* Macerate the Yellow Bark with the Alcohol for four days; then filter by means of a percolator, and, when the liquid ceases to pass, pour gradually upon the Bark sufficient Water to keep its surface covered. When the filtered tincture measures four pints, set it aside, and proceed with the filtration until six pints of infusion are obtained. Distil off the alcohol from the tincture, and evaporate the infusion, till the liquids respectively are brought to the consistence of thin honey; then mix them, and evaporate so as to form an extract." *U. S.*

"Take of Yellow Bark, coarsely powdered, *three pounds;* Distilled Water *six pints* [Imperial measure]. Add four pints of the Water to the Bark, and stir constantly with a spatula until it is thoroughly moistened; macerate for twenty-four hours, and strain through linen. Macerate what remains in the rest of the water for twenty-four hours, and strain. Then mix the liquors, and evaporate to the proper consistence." *Lond.*

"Take of any of the varieties of Cinchona, but especially the Yellow or Red Cinchona, in fine powder, *four ounces;* Proof Spirit *twenty-four fluidounces.* Percolate the Cinchona with the Spirit; distil off the greater part of the spirit; and evaporate what remains in an open vessel over the vapour-bath to a due consistence." *Ed.*

EXTRACTUM CINCHONÆ PALLIDÆ. *Lond.* EXTRACTUM CINCHONÆ. *Ed. Extract of Pale Bark.*

The *London* and *Edinburgh Colleges* prepare this from Pale Bark in the same manner as extract of yellow bark. (See *Extractum Cinchonæ Flavæ.*)

EXTRACTUM CINCHONÆ RUBRÆ. *U. S., Lond.* EXTRACTUM CINCHONÆ. *Ed. Extract of Red Bark.*

This is directed, in the Pharmacopœias recognising it, to be prepared from Red Bark in the same manner as extract of yellow bark. (See *Extractum Cinchonæ Flavæ.*)

Either of the above processes will afford an efficient extract; and they are all much preferable to the old methods, in which the virtues of the bark were extracted by boiling. The U. S. or Edinburgh process is preferable to that of the

London Pharmacopœia, as water does not thoroughly exhaust the bark, and the method of percolation is more efficient than maceration simply. It is very desirable that the evaporation, in the preparation of this extract, should be effected at a low temperature.

A very good extract of bark was formerly prepared, in the shops of Philadelphia, by macerating cinchona for a considerable length of time in a large proportion of water, and slowly evaporating the infusion, by a very moderate heat, in large shallow dishes placed upon the top of a stove. Before the use of the sulphate of quinia had superseded that of most other preparations of bark, we employed this extract with success in the treatment of intermittents, and found ten grains of it equivalent to nearly a drachm of the powdered cinchona.

According to Mr. Brande, one cwt. of fine crown bark (best pale bark) yields on an average 28 pounds of watery extract, and 25 pounds of alcoholic extract. It is best that the bark should be only coarsely powdered when submitted to decoction or maceration; as in this state it is sufficiently penetrable by the solvent, and more readily separated after being exhausted. The extract should always be brought to the hard dry state in which it may be pulverized; as it is thus less apt to be injured by exposure, and in the state of powder may be more uniformly incorporated with other substances. It is best prepared from the yellow (*Calisaya*) or the red bark.

Medical Uses. The extract of Peruvian bark is at present much less employed than before the discovery of quinia. It is still, however, occasionally prescribed as a tonic in combination with other medicines; and as it possesses, when properly prepared with a spirituous menstruum, almost all the active principles as they exist in the bark itself, it may be used in preference to the sulphate of quinia, whenever it is supposed that the latter is incapable of exerting all the curative influence of cinchona. We are told, however, that on account of the high price of Calisaya bark, much of the extract as at present in the shops is prepared from inferior varieties. The dose is from ten to thirty grains, equivalent to about a drachm of the powdered bark. W.

EXTRACTUM COLCHICI. *Lond.* *Extract of Colchicum.*

This is prepared in the manner directed for extract of aconite; the cormus being first deprived of its coating. (See *Extractum Aconiti.*)

There scarcely seems to be occasion for both this and the following extract of meadow-saffron bulb. The dose is one or two grains.

In Great Britain a preparation called *preserved juice of colchicum* is given in the dose of five minims or more. It is prepared by expressing the fresh bulb, allowing it to stand for forty-eight hours, so that the feculent matter may be deposited, then adding one-quarter of its bulk of alcohol, allowing it again to stand for a short period, and ultimately filtering. W.

EXTRACTUM COLCHICI ACETICUM. *U. S.*, *Lond.*, *Ed.*, *Dub.* *Acetic Extract of Colchicum.*

"Take of Colchicum Root, in coarse powder, *a pound;* Acetic Acid *four fluidounces;* Water *a sufficient quantity.* To the Acetic Acid add a pint of Water, and mix the resulting liquid with the Colchicum Root. Transfer the mixture to a percolator, and pour Water gradually upon it until the liquid passes with little or no taste. Lastly, evaporate the liquid, in a porcelain vessel, to the proper consistence." *U. S.*

"Take of fresh Colchicum Cormus [bulb] *a pound;* Acetic Acid *three fluidounces.* Bruise the Cormus previously deprived of its coating, gradually sprinkling in the Acetic Acid; then express the juice, and evaporate it, without straining, to the proper consistence." *Lond.*

"Take of Bulb of Colchicum *a pound;* Pyroligneous Acid [acetic acid, sp. gr.

1·034] *three fluidounces.* Beat the Colchicum to a pulp, gradually adding the Acid; express the liquor, and evaporate it in a porcelain vessel (not glazed with lead) over the vapour-bath to the due consistence." *Ed.*

"Take of Colchicum Root, dried, *four ounces* [avoirdupois]; Dilute Acetic Acid *eight fluidounces.* Digest the Root in the Acid for fourteen days, then filter, and evaporate by means of a water-bath, to the consistence of a soft extract." *Dub.*

As the fresh colchicum bulb is rarely to be had in this country, the U. S. Pharmacopœia employs the dried bulb; and its process, if properly conducted, will afford a very efficient extract. Some inconveniences are experienced in preparing the extract, according to the London process, from the recent bulb by expression, which would seem to render the U. S. process under all circumstances preferable. (*Pharm. Journ. and Trans.*, xiii. 62.)

The use of the acetic acid, in this preparation, is to render more soluble the alkaline principle upon which the virtues of meadow-saffron are thought to depend. The acetic extract of colchicum is highly commended by Sir C. Scudamore, who, however, prefers it made by evaporating to the consistence of honey, a saturated acetic infusion of the dried bulb. (*Lond. Med. Gazette*, Dec. 10, 1841.) The dose of the extract is one or two grains, to be repeated two or three times a day, and increased if necessary. W.

EXTRACTUM COLOCYNTHIDIS. *Lond., Ed.* *Extract of Colocynth.*

"Take of Colocynth, sliced and deprived of its seeds, *three pounds;* Distilled Water *half a gallon* [Imperial measure]. Macerate the Colocynth for thirty-six hours, occasionally pressing it with the hand. Express the liquor strongly and strain. Finally evaporate to the proper consistence." *Lond.*

"Take of Colocynth *a pound;* Water *two gallons.* Boil gently for six hours, replacing the evaporated water occasionally. Strain the liquor while hot; and evaporate it in the vapour-bath to the due consistence." *Ed.*

Colocynth should be deprived of its seeds, as directed by the London College, before being submitted to the action of the menstruum. Dr. Duncan found half a pound of colocynth to contain 2770 grains of seeds, which, boiled by themselves, yielded almost nothing to water. Boiling water extracts so much pectic acid and mucilage from colocynth, that the decoction or hot infusion gelatinizes on cooling. Hence the Edinburgh College directs that the decoction should be strained while hot. But the extract made in this way is loaded with inert matter, and, besides, is apt to be mouldy or so tough and hard as to resist trituration and formation into pills. Hence the London College, following in this respect the French Codex, directs in the last edition of its Pharmacopœia, maceration with cold water; but there is reason to believe that the very large proportion of colocynth ordered is a mistake; *three pounds* having probably been inadvertently substituted for *three ounces.* In the former London process, in which boiling was directed, the proportion was *a pound* of colocynth to *two gallons* of water, which is the same as *three ounces* to *half a gallon;* and it is probable that the only difference intended was the use of cold instead of boiling water. Besides, it is admitted that the *compound pill of colocynth* of the present London Pharmacopœia was designed as a substitute for the old *compound extract,* to be given in the same dose; but, if made with the present simple extract, it has been found to be much more powerful than the old preparation, so that it cannot with propriety be given in the same quantity; while, if made with simple extract prepared from three ounces of the pulp to half a gallon of water, it has precisely the same strength. (See *Pharm. Journ. and Trans.*, xii. 271, 376, and 495.) Upon the whole it will be safest to adopt the three ounces in making this preparation; in which case it may be used, as formerly recommended, in the dose of

from five grains to half a drachm; whereas if it be made in precise compliance with the formula, the dose has not been well ascertained, but would certainly be much less. This extract is little used in the United States.

Off. Prep. Enema Colocynthidis; Pilula Colocynthidis Composita. W.

EXTRACTUM COLOCYNTHIDIS COMPOSITUM. *U. S. Compound Extract of Colocynth.*

"Take of Colocynth, deprived of the seeds and sliced, *six ounces;* Aloes, in powder, *twelve ounces;* Scammony, in powder, *four ounces;* Cardamom, in powder, *an ounce;* Soap [Castile] *three ounces;* Diluted Alcohol *a gallon.* Macerate the Colocynth in the Diluted Alcohol, with a gentle heat, for four days. Express and filter the liquor, and add to it the Aloes, Scammony, and Soap; then evaporate to the proper consistence, and near the end of the process, mix the Cardamom with the other ingredients." *U. S.*

The object of the soap in this formula is to improve the consistence of the mass, which, when hardened by time, it renders more soluble in the liquors of the stomach. It may possibly also serve the purpose of qualifying the action of the aloes. Diluted alcohol is a much better solvent of the active principle of colocynth than water. The proper consistence, alluded to in this process, is that which is adapted to the formation of pills; but as it is very convenient to have it in the state of powder for admixture with other substances, a portion of the extract should be evaporated to dryness, by exposing it in thin layers to dry air for a few days.

This extract is an energetic and safe cathartic, possessing the activity of its three purgative ingredients, with comparatively little of the drastic character of the colocynth and scammony. It may be still further and advantageously modified by combination with rhubarb, jalap, calomel, &c., with one or more of which it is very often united in prescription. In such combination it is much employed wherever an active cathartic is desirable, particularly in the commencement of fevers and febrile complaints, in congestion of the liver or portal system, and in obstinate constipation. In small doses it is an excellent laxative in that state of habitual costiveness, depending on a want of the due irritability of the bowels, which often occurs in old people. The dose is from five to thirty grains, according to the effect to be produced, and the susceptibility of the bowels. A very eligible combination is the compound cathartic pill of the U. S. Pharmacopœia. We are informed that much of the extract sold in this country is made with inferior scammony and aloes, and an insufficient proportion of colocynth, so that it is comparatively inert. Cheap compound extract of colocynth should be looked on with suspicion, and the apothecary should prepare it for himself.

Off. Prep. Pilulæ Catharticæ Compositæ. *U. S.* W.

EXTRACTUM CONII. *U. S., Lond., Ed., Dub. Extract of Hemlock.*

"Take of fresh Hemlock Leaves *a pound.* Bruise them in a stone mortar, sprinkling on them a little water; then express the juice, and, having heated it to the boiling point, filter it, and evaporate to the proper consistence, either in a vacuum with the aid of heat, or in shallow vessels, at ordinary temperatures, by means of a current of air directed over the surface of the liquid." *U. S.*

The *London College* directs this extract to be made in the same manner as extract of aconite (see *Extractum Aconiti*), and the *Dublin*, as extract of belladonna (see *Extractum Belladonnæ*).

"Take of Conium *any convenient quantity.* Beat it into a uniform pulp in a marble mortar, express the juice, and filter it. Let this juice be evaporated to the consistence of a very firm extract, either in a vacuum with the aid of heat, or spontaneously in shallow vessels exposed to a strong current of air freed of

dust by gauze-screens. This extract is of good quality only when a very strong odour of conia is disengaged by degrees on its being carefully triturated with Aqua Potassæ." *Ed.*

The most important point in the preparation of this extract is to evaporate the juice without an undue degree of heat. At a temperature of 212° or upwards, its active principle undergoes rapid decomposition, being converted into resinous matter and ammonia. This is detected by the operator by the ammoniacal odour mixed with that which is peculiar to the plant. The juice always to a certain extent undergoes this decomposition when evaporated over a fire, and is not exempt from it even when the heat is regulated by a water-bath. Hence the propriety of the directions in the U. S. and Edinburgh Pharmacopœias. An excellent plan in the evaporation is to conduct it first in a vacuum, and afterwards in shallow vessels with a current of air at common temperatures. By the present U. S. process, which is an improvement upon that of the former edition of the Pharmacopœia, the extract is procured in a more concentrated state by heating the juice to the boiling point and then filtering, whereby the inert albumen is coagulated, and, along with the equally inert chlorophylle and vegetable fibre, is separated from the liquid before evaporation. Long-continued exposure to the air is productive of the same result as too much heat, so that old extracts are frequently destitute of activity. (*Journ. de Pharm.*, xxii. 416.) No one of the extracts is more variable in its qualities than this. The season at which the herb is collected, the place and circumstances of its growth, the method of preparing the extract, are all points of importance, and are all too frequently neglected. (See *Conii Folia.*) In this country the process is often very carelessly conducted; and large quantities of an extract, prepared by boiling the plant in water and evaporating the decoction, have been sold as the genuine drug. The apothecary should always prepare the extract himself, or procure it from persons in whom he can have entire confidence. That imported from London has usually been considered the best; but we have seen and tried the extract prepared by the Messrs. Tilden and Co., of New York, by evaporation in vacuo at a low heat, and have found it superior to any that we had previously employed. It is not improbable that, as suggested to us by Professor Procter, the addition of a portion of acetic acid to the juice before evaporation, might tend to fix the conia, and enable it better to resist the influence of heat than in its native combination. The activity of any specimen of the extract may be in some measure judged of by rubbing it with potassa, which, disengaging the *conia* and rendering it volatile, gives rise to the peculiar mouse-like odour of that principle. If no odour be evolved under these circumstances, the extract may be deemed inert.

The extract of hemlock prepared without separating the chlorophylle has a fresh olive or green colour; but made according to the U. S. process is brownish. It should have a strong narcotic somewhat fetid odour, and a bitterish saline taste. According to Brande, from three to five pounds are obtained from one cwt. of the leaves. M. Recluz got rather more than an ounce from sixteen ounces. Of the medical properties and application of this extract, we have spoken under the head of Conii Folia. The dose is two grains two, three, or four times a day, to be gradually increased till evidences of its action upon the system are afforded. It may be administered in pill or solution.

Off. Prep. Cataplasma Conii; Pilula Conii Composita. W.

EXTRACTUM CONII ALCOHOLICUM. *U. S. Alcoholic Extract of Hemlock.*

This is prepared, according to the U. S. Pharmacopœia, from Hemlock Leaves, in coarse powder, in the manner directed for alcoholic extract of aconite. (See *Extractum Aconiti Alcoholicum.*)

This is one of the French officinal extracts, and, when well made from recently and carefully dried leaves, is a good preparation. The same caution is requisite in evaporating in this case as in that of the inspissated juice or common extract. The dose, to begin with, is two or three grains. W.

EXTRACTUM DIGITALIS. *Ed.* *Extract of Foxglove.*

This is prepared from the fresh leaves, in the manner directed by the *Edinburgh College* for extract of hemlock. (See *Extractum Conii.*)

This preparation appears to us, considering the activity of the leaves themselves, and the at least equal uncertainty of the extract, to be quite superfluous. The dose is from half a grain to two grains. W.

EXTRACTUM DULCAMARÆ. *U. S.* *Extract of Bittersweet.*

This is prepared, according to the U. S. Pharmacopœia, from Bittersweet, in coarse powder, in the manner directed for extract of gentian. (See *Extractum Gentianæ.*)

The preparation is well known on the continent of Europe, but little used in this country or Great Britain. The dose is from five to ten grains; but much more may be given with impunity. W.

EXTRACTUM GENTIANÆ. *U.S.*, *Lond.*, *Ed.*, *Dub.* *Extract of Gentian.*

"Take of Gentian, in coarse powder, *a pound;* Water *a sufficient quantity.* Mix the Gentian with a pint of Water, and, after allowing the mixture to stand for twenty-four hours, transfer it to a percolator, and pour Water upon it gradually until the liquid passes but slightly impregnated with the properties of the Gentian. Heat the filtered liquor to the boiling point, strain, and evaporate to the proper consistence." *U. S.*

"Take of Gentian, sliced, *three pounds;* Distilled Water *six pints* [Imperial measure]. Macerate for twelve hours in four pints of the Water; pour off the liquor and strain. To the residue add two pints of the Water, macerate for six hours, and lightly express the liquor and strain. Lastly, having mixed the liquors, evaporate to the proper consistence." *Lond.*

The *Dublin* process does not differ essentially from that of the London College.

"Take of Gentian *any convenient quantity.* Bruise it to a moderately fine powder, mix it thoroughly with half its weight of Distilled Water; in twelve hours put it into a proper percolator, and exhaust it by percolation with temperate Distilled Water; concentrate the liquid, filter it before it becomes too thick, and evaporate in the vapour-bath to the due consistence." *Ed.*

The London and Dublin Colleges have very properly abandoned decoction in preparing this extract, but have not adopted percolation as employed in the U. S. and Edinburgh processes, which is a great improvement over the plan of maceration. The extract, however, may be advantageously made by macerating the root in two parts of water for thirty-six hours, then expressing in a powerful press, again macerating with additional water and in like manner expressing, and evaporating the united expressed liquors. MM. Guibourt and Cadet de Vaux obtained by maceration in cold water an extract not only greater in amount, but more transparent, more bitter, and possessing more of the colour and smell of the root than that prepared by decoction. Guibourt attributes this result to the circumstance that, as gentian contains little if any starch, it yields nothing to boiling which it will not also yield to cold water; while decoction favours the combination of a portion of the colouring matter with the lignin. But this opinion requires modification, now that it is understood that gentian contains pectic acid, which water will extract when boiling hot, but not when cold. For observations in relation to the best modes of evaporation in the

formation of extracts, the reader is referred to page 964. Gentian, according to Brande, yields half its weight of extract by decoction.

As ordinarily procured, the extract of gentian is nearly inodorous, very bitter, of a dark-brown colour approaching to black, shining, and tenacious. It is frequently used as a tonic in the form of pill, either alone or in connexion with metallic preparations. The dose is from ten to thirty grains.

Off. Prep. Pilulæ Aloës Compositæ. W.

EXTRACTUM HÆMATOXYLI. *U. S., Lond., Ed. Extract of Logwood.*

"Take of Logwood, rasped, *a pound;* Water *a gallon.* Boil down to four pints, and strain the liquor while hot; then evaporate to the proper consistence." *U. S.*

"Take of Logwood, in fine chips, *a pound;* boiling Water *a gallon* [Imperial measure]. Macerate for twenty-four hours, then boil down to four pints, strain, and concentrate in the vapour-bath to the due consistence." *Ed.*

The *London College* takes *two pounds and a half* of sliced logwood and *two gallons* [Imperial measure] of boiling distilled water; macerates for twenty-four hours, then boils down to a gallon, and strains the liquor while hot; and lastly evaporates to the proper consistence.

The evaporation should be carried so far that the extract may be dry and brittle when cold. About twenty pounds of it are obtained from one cwt. of logwood. (*Brande.*) It is of a deep ruby colour, and an astringent sweetish taste; and possesses all the medical virtues of the wood. If given in pills, these should be recently made, as, when long kept, they are said to become so hard as sometimes to pass unchanged through the bowels. The extract, however, is best administered in solution. The dose is from ten to thirty grains. This extract is said to be prepared largely in Yucatan and other parts of Mexico. W.

EXTRACTUM HELLEBORI. *U. S. Extract of Black Hellebore.*

This is prepared, according to the U. S. Pharmacopœia, from Black Hellebore, in coarse powder, in the manner directed for alcoholic extract of aconite. (See *Extractum Aconiti Alcoholicum.*)

In consequence, probably, of the injurious influence of heat upon black hellebore, the watery extract prepared by decoction is little if at all stronger than the root. The process of percolation with cold spirit, has, therefore, been adopted in the last edition of the U. S. Pharmacopœia; and, if proper attention be paid to conduct the evaporation at as low a temperature, and with as little exposure to the air as possible, an efficient extract will probably be obtained. Care should be taken to separate from the sides of the vessel any of the resin deposited during the evaporation, and mix it with the rest. The extract operates as a drastic purge in the dose of twelve or fifteen grains, but is seldom employed.

The former French Codex contained a process for preparing the extract of hellebore, according to the method of Bacher. Two pounds of the root and half a pound of carbonate of potassa are digested, with a moderate heat, for twelve hours, in eight pounds of alcohol of 22° B.; the tincture is strained with expression; the residuum is again digested with eight pounds of white wine for twenty-four hours; the wine is expressed, and having stood four hours to settle is decanted; the liquors are then mixed, and with a gentle heat evaporated to the consistence of an extract. One ounce of this extract, mixed with the same quantity of myrrh, and with ten scruples of the powdered leaves of Centaurea benedicta, and made into pills of one grain each, constitutes the preparation known as the *tonic pills of Bacher*, formerly much used in amenorrhœa and dropsy, and probably not without advantage, especially in the former of these diseases. The dose is from ten to twenty pills during the day. An additional

quantity of diluted alcohol might, without disadvantage, be substituted for the wine in the preparation of the extract. W.

EXTRACTUM HYOSCYAMI. *U. S., Lond., Ed., Dub. Extract of Henbane.*

This is prepared from fresh Henbane Leaves in the manner directed by the U. S. Pharmacopœia for extract of stramonium leaves (see *Extractum Stramonii Foliorum*), by the *London* for extract of aconite (see *Extractum Aconiti*), by the *Edinburgh* for extract of hemlock (see *Extractum Conii*), and by the *Dublin* for extract of belladonna (see *Extractum Belladonnæ*).

MM. Solon and Soubeiran have shown that the insoluble matter separated from the expressed juice of henbane by filtering, and that coagulated by heat, are nearly, if not quite, inert; so that the juice may be advantageously clarified before evaporation. (*Amer. Journ. of Pharm.*, viii. 228.) Extract of henbane is derived chiefly from England. It is at present, however, prepared by the Messrs. Tilden & Co., of New York, by the vacuum process. Mr. Braude says that one cwt. of the fresh herb affords between four and five pounds. M. Recluz obtained about one part from sixteen.

The extract, as it reaches us, is of a dark-olive colour almost black, of a narcotic rather unpleasant odour, and a bitterish, nauseous, slightly saline taste. It retains its softness for a long time; but at the end of three or four years becomes dry, and exhibits, when broken, small crystals of nitrate of potassa and chloride of sodium. (*Recluz.*) Like all the inspissated juices it is of variable strength, according to its age, the care used in its preparation, and the character of the leaves from which it was procured. (See *Hyoscyamus.*)* In its use, therefore, it is advisable to begin with a moderate dose, two or three grains for instance, and gradually to increase the quantity till some effect is experienced, and the degree of efficiency of the particular parcel employed is ascertained. It is usually given in pill. It is sometimes used externally for the same purposes as extract of belladonna.

Off. Prep. Pilulæ Colocynthidis et Hyoscyami. W.

EXTRACTUM HYOSCYAMI ALCOHOLICUM. *U.S. Alcoholic Extract of Henbane.*

This is prepared, according to the U. S. Pharmacopœia, from Henbane Leaves, in coarse powder, in the manner directed for alcoholic extract of aconite. (See *Extractum Aconiti Alcoholicum.*)

The alcoholic extract of henbane, if prepared from recently dried leaves, is thought to be more uniform and powerful than the inspissated juice or common extract. It is one of the preparations of the French Codex. The dose is one or two grains, to be gradually increased until its effects are obtained. W.

EXTRACTUM JALAPÆ. *U. S., Lond. Extract of Jalap.*

This is prepared, according to the U. S. Pharmacopœia, from Jalap, in coarse powder, in the manner directed for extract of yellow bark. (See *Extractum Cinchonæ Flavæ.*)

* Much depends on the choice of the leaves; and too little attention is paid to this point. In reference to the biennial plant, there seems to be no doubt that the leaves of the second year are much more efficacious than those of the first, and should, therefore, always be selected. It is stated under Hyoscyamus, in the first part of this work, that the leaves should be gathered soon after the plant has flowered. Mr. Charles Cracknell gives more particular directions. He thinks that the plant is in a fit state for collection only during a very short period, when the flowers at the top are blown, but have not yet begun to fade, and the seed-vessels and seeds which have been formed are still soft and juicy. For other observations on the preparation of this extract, see a paper by Mr. Cracknell in the *Am. Journ. of Pharm.* (23, 245), from *Pharm. Journ. and Trans.*, March, 1851.

"Take of Jalap, in powder, *two pounds and a half;* Rectified Spirit *a gallon* [Imperial measure]; Distilled Water *two gallons* [Imperial measure]. Macerate the Jalap in the Spirit for four days, and pour off the tincture. Boil the residue in the Water down to half a gallon. Filter the tincture and decoction separately; then distil the former and evaporate the latter until they thicken. Lastly, mix the extract with the resin, and evaporate to the proper consistence. Let the extract be kept *soft*, fit for forming pills, and *hard*, so that it may be powdered." *Lond.*

Jalap contains a considerable quantity of starch, which is extracted by decoction, but left behind by cold water. As this principle serves only to impede the filtration or straining, and augment the bulk of the extract, without adding to its virtues, the U. S. process, in which the water is employed at common temperatures, is preferable to the London, in which decoction is resorted to. The use both of alcohol and water is necessary, in order to extract all the medicinal qualities of the drug, and they are employed successively, under the impression that the previous removal of the resin by the former, facilitates the action of the latter. The use of percolation, as directed by the U. S. Pharmacopœia, enables the cold water to extract the soluble parts without the long maceration which would otherwise be necessary. According to Cadet de Gassicourt, water at ordinary temperatures, and in the old mode, acts so slowly, that fermentation takes place before the active matter is all dissolved. Hence, if the extract is prepared without percolation, the residuum, after the tincture has been decanted, should be digested with water at a heat of about 90° or 100° F., which, while it is insufficient for the solution of the starch, enables the solvent to take up the active matter with sufficient rapidity.

One cwt. of jalap affords, according to Mr. Brande, about fifty pounds of aqueous extract and fifteen of resin. The product of the former is somewhat less by infusion than decoction; and the extract is proportionably stronger.

The extract of jalap is of a dark-brown colour, slightly translucent at the edges, and tenacious when not perfectly dry. It contains the resin and gummy extractive, and, consequently, has all the medical properties of the root; but it is not often exhibited alone, being chiefly used as an ingredient of purgative pills, for which it is adapted by its comparatively small bulk. The dose is from ten to twenty grains, or rather more than half that of jalap.

Off. Prep. Pilulæ Catharticæ Compositæ; Pulvis Scammonii Comp. W.

EXTRACTUM *sivè* RESINA JALAPÆ. *Ed.* *Extract* or *Resin of Jalap.*

"Take *any convenient quantity* of Jalap, in moderately fine powder; mix it thoroughly with enough of Rectified Spirit to moisten it well; put it in twelve hours into a percolator, and exhaust the powder with Rectified Spirit; distil off the greater part of the Spirit, and concrete the residuum over the vapour-bath to a due consistence." *Ed.*

This process yields the resin of jalap in an impure state. It may be obtained pure by pouring boiling water on the roots, macerating for a day, then cutting them into very thin slices, boiling them three times successively for about ten minutes in water, expressing after each decoction, afterwards boiling them as often and as long in alcohol, and in like manner expressing, finally mixing the tinctures, treating the liquor with animal charcoal, filtering, and evaporating. (Nativelle, *Journ. de Pharm.*, 3e *sér.*, i. 228.) Another mode is to introduce into a displacement instrument, first one part of finely powdered animal charcoal, and afterwards two parts mixed with an equal quantity of powdered jalap, then to pour on alcohol until the liquid which passes equals the jalap, and finally to add to the tincture thus obtained twice its volume of water, so as to precipitate the resin, which is to be washed and dried. (*Christison's Dispensatory.*) The

pure resin is as white as starch, and in doses of from three to five grains is said to purge actively. For use, however, the Edinburgh preparation is sufficiently pure. It is dark-coloured, brittle, and of a shining fracture.

Guaiac is said to be sometimes fraudulently added to the resin of jalap. It may be detected by the green colour it produces, when a few drops of solution of chloride of soda or of lime are added to an alcoholic solution of the suspected resin. (*Journ. de Pharm.*, 3*e sér.*, x. 357.) According to G. A. Kaiser, jalap resin may be distinguished from all other resins by being gradually dissolved by concentrated sulphuric acid, and depositing, after some hours, a brown soft viscid matter. (*Chem. Gaz.*, Jan. 1845, from *Liebig's Annalen.*)

It is now generally believed that the resin of jalap is its sole purgative principle, the gummy extractive being perhaps diuretic. The U. S. or London extract better represents the whole virtues of jalap, and should be preferred when its peculiar hydragogue operation is required. The Edinburgh extract or resin is more powerfully purgative, but is also harsh, and apt to operate painfully. To obviate this effect it is advised that it should be triturated with loaf-sugar, sulphate of potassa, almond emulsion, or other substance calculated to separate its particles. The dose is from four to twelve grains. W.

EXTRACTUM JUGLANDIS. *U.S.* *Extract of Butternut.*

This is prepared from the inner bark of the root of *Juglans cinerea*, in coarse powder, in the manner directed for extract of gentian. (See *Extractum Gentianæ.*)

This extract was formerly for the most part prepared by the country people, who are said to have used the bark of the branches, and even the branches themselves, instead of the inner bark of the root, as directed by the Pharmacopœia; and to have injured the preparation by too much heat. That it should have proved uncertain in the hands of many physicians is, therefore, not a matter of surprise. It should be prepared by the apothecary, and from the inner bark of the root gathered in May or June. Experiments are yet wanting to prove that water is the best solvent of the active principles of this bark. Prof. Procter informs us that he has found an extract of the fresh bark prepared with diluted alcohol to have much more of the pungency of the bark than the officinal.

The extract of butternut is of a black colour, sweetish odour, and bitter astringent taste. In the dose of twenty or thirty grains, it acts as a mild cathartic. (See *Juglans.*) W.

EXTRACTUM KRAMERIÆ. *U.S.*, *Ed.* *Extract of Rhatany.*

This is prepared from Rhatany, in coarse powder (*U.S.*), or in moderately fine powder (*Ed.*), in the manner directed for extract of gentian. (See *Extractum Gentianæ.*)

In selecting a process for the preparation of this extract, it was undoubtedly wise to adopt the mode of displacement, with cold water as the menstruum. (See *page* 436.) It is absolutely necessary to the success of this process, that the root should be well and uniformly comminuted; and the "moderately fine powder" of the Edinburgh Pharmacopœia is, therefore, preferable to the "coarse powder" of our own. The wood of the root yielded to Prof. Procter only 6·8 per cent. of extract, while the bark separated from the wood yielded 33 per cent. As the wood is of difficult pulverization, the inference is obvious, that, in powdering the roots, the ligneous portion may be rejected with advantage. (*Am. Journ. of Pharm.*, xiv. 270.) As a prolonged exposure of the infusion to the air is attended with the absorption of oxygen, and the production of insoluble apotheme, it is desirable that the evaporation should be conducted rapidly or in a vacuum. There scarcely appears to be occasion, in the case of rhatany, for heating and filtering the infusion before evaporation, the only use of which is to get rid of albumen, which is not among the recognised ingredients of the root.

Very inferior extracts of rhatany are often found in the shops. Such is the South American extract, which has been occasionally imported. As the product obtained by decoction is greater than that afforded by the officinal plan, the temptation to substitute the former is not always resisted, although it has been shown to contain nearly 50 per cent. of insoluble matter. Some druggists prepare the extract with an alcoholic menstruum with a view to the greater product; but the extract thus prepared has from 20 to 30 per cent. less of the active principle than the officinal. A substance was shown to us by a respectable apothecary of this city, said to have been imported as extract of rhatany from Europe, which was nearly tasteless, and was plausibly conjectured to be the dried coagulated matter of old tincture of kino.

Extract of rhatany should have a reddish-brown colour, a smooth shining fracture, and a very astringent taste; and should be almost entirely soluble in water. Its virtues may be considered as in proportion to its solubility. It is much used for all the purposes for which the astringent extracts are employed. The dose is from ten to twenty grains.

Off. Prep. Syrupus Krameriæ. W.

EXTRACTUM LATUCÆ. *Lond.* *Extract of Lettuce.*

This extract is prepared by the *London College* from fresh Lettuce leaves in the same manner as extract of aconite. (See *Extractum Aconiti.*)

The claims of this extract to favourable notice are at least very questionable. Consisting chiefly of the common sap of the plant, which is inert, with a variable, but always small proportion of the milky secretion, on which the activity of lettuce depends, it is at best a feeble and uncertain preparation. Lactucarium possesses all its virtues, with more strength and uniformity of action. The dose of the extract is from five to fifteen grains. W.

EXTRACTUM LUPULI. *Lond., Ed.* *Extract of Hops.*

"Take of Hops *two pounds and a half;* boiling Distilled Water *two gallons* [Imperial measure]. Macerate for twenty-four hours; then boil to a gallon, and strain the liquor while hot; lastly, evaporate to the proper consistence." *Lond.*

The *Edinburgh College* prepares this in the same manner as extract of logwood. (See *Extractum Hæmatoxyli.*)

Since the discovery of the fact that the active properties of hops reside chiefly in the lupulin, this extract has not been deemed an eligible preparation, and has been little used. It has the bitterness of the strobiles without their aroma. Lupulin may be advantageously substituted for it in all cases in which it was formerly employed. Mr. Brande says that the average yield of one cwt. of hops is forty pounds of the extract. The dose is from ten to thirty grains.

Under the inappropriate name of *humuline*, an extract has been prepared by first treating hops with alcohol and subsequently with water, evaporating the tincture and infusion separately, and mixing the products. (*Pharm. Journ. and Trans.*, xiii. 231.) W.

EXTRACTUM NUCIS VOMICÆ. *U.S., Lond., Ed.* *Extract of Nux Vomica.*

"Take of Nux Vomica *a pound;* Alcohol *a sufficient quantity.* Expose the Nux Vomica to steam till it is softened; then, having sliced and dried it, grind it into powder. Introduce it into a percolator, and pour Alcohol upon it gradually until the liquid passes without bitterness. Distil off the greater part of the alcohol from the filtered liquor, and evaporate the residue to the proper consistence." *U. S.*

The *Edinburgh College* treats the nux vomica in the same manner, grinding it to powder in a coffee-mill; then exhausts it with rectified spirit, either by percolation or repeated decoction; and completes the process as above directed.

"Take of Nux Vomica *eight ounces;* Rectified Spirit *three pints* [Imperial measure]. Apply steam to the Nux Vomica so that it may be softened. Having cut it into thin slices, bruise, dry, and macerate it for seven days in two pints of the Spirit. Express the tincture and filter. Macerate what remains in the rest of the Spirit for three days; then again express and filter. Having mixed the tinctures, distil off the greater part of the spirit, and evaporate the remainder to the proper consistence." *Lond.*

This extract is an active preparation of nux vomica, though not always of uniform strength, owing to the variable proportion of strychnia in the substance from which it is prepared. M. Recluz obtained from sixteen ounces of nux vomica the average product of one ounce and a quarter. The dose of the extract is from half a grain to two grains, to be repeated three times a day.* W.

EXTRACTUM OPII. *U. S., Lond., Ed.* EXTRACTUM OPII AQUOSUM. *Dub. Extract of Opium.*

"Take of Opium *a pound;* Water *five pints.* Cut the Opium into small pieces, macerate it for twenty-four hours in a pint of the Water, and reduce it to a soft mass by trituration. Express the liquid, and treat the residue with each of the four remaining pints of Water successively in the same manner. Mix the liquors, filter, and evaporate by means of a water-bath to the proper consistence." *U. S.*

"Take of Opium, in powder, *a pound and a half;* Distilled Water *five pints* [Imperial measure]. To the Opium add gradually two pints and a half of the Water, and macerate for twenty-four hours, occasionally stirring with a spatula; then strain. Macerate the residue in the rest of the Water for twenty-four hours and strain. Lastly, evaporate the strained liquors to the proper consistence." *Lond.*

The *Edinburgh* and *Dublin* processes correspond essentially with that of the U. S. Pharmacopœia.

An advantage of this preparation is that, by the solubility of the extract in water, it affords a convenient method of obtaining quickly an aqueous solution of the active ingredients of opium. It is exceedingly doubtful whether anything is left behind after the opium has been exhausted by water, which materially modifies the action of its anodyne principle; and the extract probably has no advantage on this account over opium. Nor has it the advantage of greater uniformity; as the gum, extractive, &c., taken up by the water, bear no fixed proportion to the active ingredients.

Denarcotized Extract of Opium. Under the impression that the stimulating and unpleasant effects of opium are owing to the narcotina, it has been proposed to separate that principle by treating the extract with ether, which dissolves the narcotina and leaves the morphia with the other ingredients. Robiquet employed cold ether; but M. Dublanc, convinced that the whole of the narcotina was not thus extracted, proposed the following plan. "Take of watery extract of opium 16 ounces; dissolve it in 8 ounces of distilled water; introduce the solution into the water-bath of a still; pour upon it 104 ounces of pure ether; distil off 24 ounces of the ether; take apart the apparatus and decant the ether which floats on the top of the extract; wash the latter while hot with the distilled ether; concentrate the residual matter, dissolve it in distilled water, filter

* Professor Procter informs us, as the result of his own observations, that in the alcoholic extract of nux vomica there is a considerable proportion of fixed oil (℥iij from ℥xvi of the seeds), which will not remain mixed with the other ingredients, becoming fluid in summer, and concreting in cold weather. This he thinks should be separated from the extract, and shaken with a little diluted alcohol, which separates any adhering active matter from it. The washings should be evaporated, and the residuum mixed with the extract; the fatty matter being thrown away.—*Note to the tenth edition.*

the solution, and evaporate to a proper consistence." It is very doubtful, however, whether any useful end is gained by this expensive operation, as it is not by any means conclusively settled that narcotina does in fact produce the unpleasant effects which have been attributed to it; and, even admitting the fact, the preparations of morphia, which are of uniform strength, are greatly preferable to the *denarcotized extract.*

The dose of the extract of opium prepared by the U. S., Edinburgh, or Dublin process is about one-half that of opium itself. The London extract, according to Brande, is never stronger, and is sometimes weaker than opium. This statement, however, has reference to the preparation of the Pharmacopœia of 1836. In the present, the maceration is continued longer, but is still probably insufficient. Recluz obtained from sixteen ounces of opium an average product of nine ounces by hot water and six by cold.

Off. Prep. Emplastrum Opii; Vinum Opii. W.

EXTRACTUM PAPAVERIS. *Lond., Ed. Extract of Poppy.*

"Take of Poppy [capsules], freed from their seeds, and bruised, *fifteen ounces;* boiling Distilled Water *a gallon* [Imperial measure]. Macerate for twenty-four hours, then boil down to four pints, and strain the liquor while hot; lastly, evaporate to the proper consistence." *Lond.*

The *Edinburgh* process corresponds closely with the above; boiling water simply, instead of boiling distilled water being employed, and evaporation over the vapour-bath directed.

Mr. Brande observes in relation to this extract, that if prepared over the open fire it is often nearly inert. He states, moreover, that it is apt to be of a troublesome consistence, too hard to be formed into pills, and too tough to be pulverized; and advises that it should always be carefully dried till it becomes sufficiently brittle to admit of being reduced to powder. One cwt. of the capsules, without the seeds, yields, according to this author, the average product of 35 pounds of extract. M. Meurein gives particular directions for making an alcoholic extract of poppy capsules, which may be consulted with advantage by those who may be called on to supply any demand for this preparation. (See *Journ. de Pharm.* 3e *sér.*, xxiii. 341.) We are told that an extract is prepared in this country from the whole herb, cut after the fruit has formed, but while it is yet green. This of course is not the officinal extract, and should not be used as such. The capsules exclusively should be used; and the best time for collecting them is after they have begun to become yellowish, but are not yet dry.

This preparation is little used in the United States. It possesses the virtues of opium, but is much inferior and less uniform in strength. The dose is from five to ten grains. W.

EXTRACTUM PAREIRÆ. *Lond., Ed. Extract of Pareira Brava.*

This is prepared by the *London College* from sliced Pareira Brava in the manner directed for extract of logwood. (See *Extractum Hæmatoxyli.*)

The *Edinburgh College* directs the root to be cut into small chips, dried thoroughly with a gentle heat, then reduced to a moderately fine powder, and treated as directed for the extract of gentian. (See *Extractum Gentianæ.*)

The dose is from ten grains to half a drachm. W.

EXTRACTUM PODOPHYLLI. *U. S. Extract of May-apple.*

This is prepared from the root of *Podophyllum peltatum,* in coarse powder, in the manner directed for the extract of yellow bark. (See *Extractum Cinchonæ Flavæ.*)

It is possessed of the purgative properties of the root, and may be given in the dose of from five to fifteen grains, but is little employed. It might be substituted in all cases for the extract of jalap.

From experiments made by Mr. John R. Lewis, it is probable that the alcoholic extract would be much more powerful as a purgative than the officinal preparation; but it does not follow that it would be more serviceable. (See *Am. Journ. of Pharm.* xix. 170.) W.

EXTRACTUM QUASSIÆ. *U. S., Ed.* *Extract of Quassia.*

This is prepared, according to the U. S. Pharmacopœia, from the raspings of Quassia, in the manner directed for the extract of gentian. (See *Extractum Gentianæ.*)

The *Edinburgh College* prepares it by cutting the quassia into small chips, drying it thoroughly with a gentle heat, reducing it to a moderately fine powder, and proceeding as directed for the extract of gentian.

According to M. Recluz, sixteen ounces of quassia yield by infusion in water seven drachms of extract; by maceration in alcohol of 19° Baumé, two ounces five drachms and a half. The difference between these quantities is so great that we suspect some mistake in the table of the Dictionnaire des Drogues from which we quote.

The extract of quassia is dark-brown or black, and excessively bitter. It is apt to become dry and disposed to crumble by time. It concentrates a greater amount of tonic power within a given weight than any other extract of the simple bitters; and may, therefore, be given with great advantage in cases in which it is desirable to administer this class of substances in as small a bulk, and with as little inconvenience to the patient as possible. The dose is about five grains, to be given in the form of pill. W.

EXTRACTUM RHEI. *U. S., Lond., Ed., Dub.* *Extract of Rhubarb.*

"Take of Rhubarb, in coarse powder, *a pound;* Diluted Alcohol *a sufficient quantity.* Mix the Rhubarb with an equal bulk of coarse sand, moisten it thoroughly with Diluted Alcohol, and, having allowed it to stand for twenty-four hours, put it into a percolator, and add Diluted Alcohol gradually until four pints of filtered liquor are obtained; then, by means of a water-bath, evaporate to the proper consistence." *U. S.*

"Take of Rhubarb, in powder, *fifteen ounces;* Proof Spirit *a pint* [Imperial measure]; Distilled Water *seven pints* [Imp. meas.]. Macerate for four days, then strain, and set the liquor by that the dregs may subside. Pour off the clear liquor, and evaporate it to the proper consistence." *Lond.*

"Take of Rhubarb *one pound;* Water *five pints* [Imp. meas.]; cut the Rhubarb into small fragments, macerate it for twenty-four hours in three pints of the Water, filter the liquor through a cloth, and express it with the hands or otherwise moderately; macerate the residuum with the rest of the Water for twelve hours at least, filter the liquor with the same cloth as before, and express the residuum strongly. The liquors, filtered again if necessary, are then to be evaporated together to a proper consistence in the vapour-bath. The extract, however, is obtained of finer quality, by evaporation in a vacuum with a gentle heat." *Ed.*

The *Dublin* process corresponds with that of the Edinburgh College.

Rhubarb yields all its active matter to water and alcohol; but, unless the evaporation is performed with great care and with a moderate heat, it is certain that the purgative principle is, to a greater or less extent, injured or dissipated in the process; and the extract may thus become even less efficient than the root. Among other consequences which result from the boiling temperature, is the formation of a compound of the tannin and starch, which is insoluble in cold water, and upon its precipitation probably carries with it a portion of the purgative principle. There is, moreover, reason to believe that this principle is

volatilizable by heat, and that a portion of it escapes with the vapour. When properly prepared the extract has decidedly the peculiar odour of rhubarb. An advantage which it possesses over the powdered root, independently of its smaller dose, is that it may be given in solution. The dose of the extract is from ten to thirty grains.

Off. Prep. Pilulæ Rhei et Ferri. W.

EXTRACTUM SARSAPARILLÆ. *U. S.* *Extract of Sarsaparilla.*

The *U. S. Pharmacopœia* prepares this extract from Sarsaparilla, in coarse powder, in the manner directed for alcoholic extract of aconite. (See *Extractum Aconiti Alcoholicum.*)

The watery extract of sarsaparilla has been very properly abandoned by the London and Dublin Colleges in the recent editions of their Pharmacopœias. Water, unless in very large proportion, is incapable of exhausting the root, and the extract could not but suffer in the long process of evaporation. Very different quantities have been obtained from different varieties of sarsaparilla, and even from different parcels of the same variety; but, as the matter taken up by boiling water consists chiefly of starch, no inference, as to the relative value of any particular specimen of the root, can be drawn from a knowledge of the quantity of watery extract which it is capable of affording.

The *spirituous extract* of the U. S. Pharmacopœia, which is the same as that of the French Codex, contains the active matter of the root. Diluted alcohol extracts all the virtues of sarsaparilla, leaving the inert fecula which encumbers the extract obtained by decoction; while the temperature requisite for the concentration of the tincture is insufficient to destroy the active principle. M. Beral obtained from 32 ounces of sarsaparilla about 4 ounces of extract by maceration with diluted alcohol. As the product of this operation is about one-eighth of the sarsaparilla employed, a drachm of the extract represents an ounce of the root. From ten to twenty grains of it may be given three or four times a day. It possesses in a high degree the acrid taste of sarsaparilla. W.

EXTRACTUM *sive* RESINA SCAMMONII. *Ed.* *Extract* or *Resin of Scammony.*

"Take *any convenient quantity* of Scammony in fine powder; boil it in successive portions of Proof Spirit till the Spirit ceases to dissolve any thing; filter; distil the liquid till little but water passes over. Then pour away the watery solution from the resin at the bottom; agitate the resin with successive portions of boiling water till it is well washed; and lastly, dry it at a temperature not exceeding 240°." *Ed.*

The only advantage of this process is that it separates the active matter of scammony from the impurities with which the drug is generally adulterated. When pure virgin scammony can be procured the extract is unnecessary. Prepared according to the above process, the resin is of a dirty greenish-brown colour, with a feeble odour and taste of scammony, and is very soluble in ether, alcohol, and boiling proof spirit. When purified with animal charcoal it has a pale brownish-yellow colour, and is without odour or taste; but retains its purgative property. The resin of scammony is liable to adulteration. Jalap resin may be detected by its insolubility in rectified ether, which dissolves that of scammony in all proportions. Sulphuric acid is the best test of common rosin or colophony, producing instantaneously with this substance an intense red colour; while in the resin of scammony it causes no immediate change. For the tests of guaiac, the reader is referred to that article in the Materia Medica. (See *Am. Journ. of Pharm.*, xxiv. 158.) When rubbed with unskimmed milk the resin of scammony forms a uniform emulsion, undistinguishable from rich milk itself. This is an excellent mode of administration. The resin should

always be given either rubbed up with some mild powder, or in emulsion. The dose is from five to twelve grains.

Off. Prep. Mistura Scammonii. W.

EXTRACTUM STRAMONII FOLIORUM. *U. S.* *Extract of Stramonium Leaves.*

"Take of Stramonium Leaves *a pound.* Bruise them in a stone mortar, sprinkling on them a little water; then express the juice, and, having heated it to the boiling point, strain, and evaporate to the proper consistence." *U. S.*

Like all the other inspissated narcotic juices, this is an uncertain preparation, varying in strength according to the care used in conducting the process, and the season at which the leaves are collected. The reader will find at page 969, and in the preliminary observations on the Extracts, some general rules which will be found useful in conducting this process, and all those of which it is the officinal type. The insoluble matter separated from the expressed juice by filtering, and that coagulated by heat, may be advantageously rejected; as, according to the observations of MM. Solon and Soubeiran, they are nearly or quite inert. M. Recluz obtained half an ounce of the extract from sixteen ounces of the leaves. The dose is a grain night and morning, to be gradually increased till it affects the system.

Off. Prep. Unguentum Stramonii. W.

EXTRACTUM STRAMONII SEMINIS. *U. S.* EXTRACTUM STRAMONII. *Lond., Ed.* *Extract of Stramonium Seed.*

"Take of Stramonium Seed, ground into powder, *a pound;* Diluted Alcohol *a sufficient quantity.* Having rubbed the powder with *half a pint* of Diluted Alcohol, introduce the mixture into a percolator, and pour upon it gradually Diluted Alcohol till the liquid passes colourless. Distil off the Alcohol from the filtered liquor, and evaporate the residue to the proper consistence." *U. S.*

"Take of Seeds of Stramonium *any convenient quantity;* grind them well in a coffee-mill. Rub the powder into a thick mass with Proof Spirit; put the pulp into a percolator, and transmit Proof Spirit till it passes colourless; distil off the spirit, and evaporate what remains in the vapour-bath to a proper consistence." *Ed.*

"Take of Stramonium seeds *fifteen ounces;* boiling Distilled Water *a gallon* [Imperial measure]. Macerate for four hours in a covered vessel near the fire; then take out the Seeds, and, after having bruised them in a stone mortar, return them to the liquor. Boil down to four pints [Imp. measure], and strain the decoction while hot. Finally, evaporate to the proper consistence." *Lond.*

The U. S. and Edinburgh processes, which may be considered identical, are preferable to the London; as the seeds yield their virtues more freely to spirit than to water alone. According to the table of Recluz, sixteen ounces of the seeds afford two ounces and two drachms of extract by maceration in diluted alcohol, and one ounce and a half by decoction. The dose to begin with is the quarter or half of a grain twice a day, to be gradually increased. W.

EXTRACTUM TARAXACI. *U. S., Lond., Ed.* *Extract of Dandelion.*

"Take of Dandelion, gathered in September, *five pounds.* Slice the Dandelion; bruise it in a stone mortar, sprinkling on it a little water, until reduced to a pulp; then express the juice, strain, and evaporate in a vacuum, or in a shallow dish over a water-bath, constantly stirring, to the proper consistence." *U. S.*

The *London College* prepares it in the same manner as extract of hops (see *Extractum Lupuli*); the *Edinburgh*, from *a pound* of the fresh root and *a gallon* (Imperial measure) of boiling water, as directed for the extract of poppy heads (see *Extractum Papaveris*).

This extract is undoubtedly stronger, prepared from the root alone than from the whole plant. It is important that the root should be collected at the right season. The juice expressed from it in the spring is thin, watery, and of a feeble flavour; in the latter part of summer, and in autumn, thick, opaque, cream-coloured, very bitter, and abundant, amounting to one-third or one-half its weight. It may be collected in August, and afterwards until severe frost. According to Mr. Squire, frost has the effect of diminishing the bitterness and increasing the sweetness of the root. An extract prepared by inspissating this juice, as now directed in the U. S. process, is much more efficient than that prepared in the old way by decoction. The inspissation should be effected by exposing the juice in shallow vessels to a current of warm dry air, or by evaporation in a vacuum, and should not be unnecessarily protracted. Long exposure, during evaporation, changes the bitterness of the juice into sweetness, which is a sign of inferiority. As often found in the shops, the extract is dark-coloured, sweet, and in all probability nearly inert. Mr. Houlton took more than an ounce of it in a day, without any sensible effect. *Pharm.* (*Journ. and Transact.*, i. 421.) When prepared from the root and leaves together, it has a greenish colour. Mr. Brande states that one cwt. of the fresh root affords from twenty to twenty-five pounds of extract by decoction in water. The expressed juice yields from 11 to 25 per cent. of extract, the greatest product being obtained in November, and the least in April and May.*

This extract deteriorates by keeping, and should, therefore, be renewed an-

* *Fluid Extract* or *Preserved Juice of Taraxacum.* The rapid change of the active principle of dandelion, under heat and exposure, renders it extremely difficult to obtain a solid extract preserving the virtues of the plant. Mr. Donovan, therefore, suggests the propriety of keeping the juice in the liquid state, and proposes a plan, by which, as he states, it may be obtained and preserved throughout the year, with nearly all its native efficiency. The whole herb, immediately after collection, is to be washed, bruised, and expressed; and the residue, having been mixed with as much water at 200° as will bring it to the consistence of a pulp, is to be allowed to stand for two hours, and then again expressed. The liquids thus obtained are to be mixed, and very slowly evaporated, in a wide earthen vessel, and with constant agitation, to one-half. The salts are thus obtained, though with little of the bitter principle. To supply this, a quantity of the roots equal to the weight of the herb first employed, is to be bruised and expressed. The resulting juice, which is in small quantity and bitter, is to be set aside; while the residual mare is to be mixed with the concentrated juice already prepared, previously brought to a boiling heat. When cold, the mixture is to be strongly expressed, and the liquor obtained to be mixed with one-sixth of its measure of alcohol. The liquor is then to be poured into quart bottles, but so as not to fill them. These are to be immersed in a vessel containing water as high as the liquid within them, and placed over a fire; the water is to be slowly heated to 180°; the bottles are to be withdrawn; and the reserved juice of the root is to be added to each in equal quantities. The space at first left in the bottles should be such that, after the addition of the juice, and the driving in of the cork, as little as possible should remain. The corks, being now cut off close to the glass, are to be covered with hard sealing-wax; and the bottles set by, inverted, in a cool place. The alcohol used is alone insufficient for the preservation of the juice; and hence the necessity of heating the bottles, and sealing them when quite full, according to *Appert's process.* Each ounce will contain about a drachm of the alcohol. (See *Am. Journ. of Pharm.*, xxiv. 65.)

Professor Procter proposes the following plan. Of the fresh roots collected in September or October, twenty pounds avoirdupois are to be sliced transversely, reduced to a pulpy mass by grinding or contusion, then thoroughly incorporated with four pints of alcohol of 0·835, and set aside in stoneware jars. After a week, or a longer time, the pulpy mass is to be subjected to strong pressure, and the liquid filtered and bottled for use. Even after six months the pulp thus treated preserves the sensible properties of the dandelion in a marked degree. Should the alcohol in the expressed liquor be objected to, it may be partially removed by a gentle evaporation by means of a water-bath until the bulk of the juice has been diminished one-sixth, and then adding eight ounces of sugar for every pint. (*Ibid.*, xxv. 408.) *Note to the tenth edition.*

nually. It is most conveniently given dissolved in cinnamon or mint water. The dose is from a scruple to a drachm three times a day.

Off. Prep. Pilulæ Ferri Sulphatis. W.

EXTRACTUM UVÆ URSI. *Lond.* *Extract of Uva Ursi.*

The *London College* prepares this extract in the manner directed for extract of hops. (See *Extractum Lupuli.*)

The dose is from five to thirty grains. W.

EXTRACTA FLUIDA.

Fluid Extracts.

These were first introduced into the U. S. Pharmacopœia of 1850, as a distinct class of preparations; the fluid extract of sarsaparilla being the only one previously directed, either in our own officinal code or by the British Colleges. Their distinctive character is the concentration of the active ingredients of medicinal substances into a small bulk, in the liquid form. Independently of the greater convenience of administration, the advantages of this class of preparations are, in relation to all of them, that the evaporation not being carried so far as in the ordinary extracts, the active principles are less liable to be injured by heat; and, in relation to a certain portion, the fluid extract of cubebs for example, that they afford the only method of concentration, as it would be impossible to obtain in a solid extract the whole activity of the medicine, depending as it does, in part, upon an essentially liquid substance. The main difficulty in relation to them, is the liability of substances in the liquid state to undergo spontaneous decomposition. This is counteracted in some of the fluid extracts by means of sugar. In others, the nature of the ingredient is preservative. A glance at the several preparations will show that there are two distinct sets of them. In one set, the principles extracted are mainly volatile oil and resin, and the menstruum employed is ether. They have been known for some time in pharmacy by the name of *oleo-resins*. In their preparation, the active matter is readily yielded to ether, while principles which might contribute to the decomposition of the extract are left behind by that menstruum. The low temperature at which the ether evaporates enables the whole of the volatile oil to be retained in the residue; and the preparation keeps well, as it contains no water to favour its decomposition. In the second set of the fluid extracts, the active matter is extracted by diluted alcohol, and the greater part of the alcohol afterwards evaporated. A portion, however, remains, which contributes towards the preservation of the preparation; but this alone is insufficient, and it is necessary to have recourse to sugar, which has the subsidiary advantage of improving the flavour. But in these fluid extracts, instead of two pounds of sugar to each pint of the liquid, as in the case of the ordinary syrups, it is generally sufficient to add an ounce for every fluidounce. Sometimes there is an advantage in adding to the preservative influence of the sugar, that of some other substance having a similar effect, as of Hoffmann's anodyne liquor in the fluid extract of senna. W.

EXTRACTUM CUBEBÆ FLUIDUM. *U. S.* *Fluid Extract of Cubebs.*

"Take of Cubebs, in powder, *a pound;* Ether *a sufficient quantity.* Put the Cubebs into a percolator, and, having packed it carefully, pour Ether gradually upon it until two pints of filtered liquor are obtained; then distil off by means of a water-bath, at a gentle heat, a pint and a half of the ether, and expose the residue, in a shallow vessel, until the whole of the ether has evaporated." *U. S.*

This is one of the *oleo-resins*, and consists mainly of the volatile oil and resin,

with a portion of the cubebin and waxy matter of the cubebs. The consistence differs with the character of the cubebs employed; its degree of fluidity being proportionate to the amount of volatile oil contained in the medicine. The colour is usually brownish, with more or less of a greenish hue, according to the quantity of chlorophylle present, which varies with the character of the cubebs, and with that of the menstruum; pure ether extracting the green colouring matter preferably, while ordinary alcoholic ether extracts also the brown. Cubebs yield from one-eighth to one-fifth of their weight of fluid extract. The preparation is apt in time to deposit waxy matter and crystals of cubebin. It was first introduced into use by Prof. Procter. (See *Am. Journ. of Pharm.*, xviii. 168.) The dose is from five to thirty minims, which may be given suspended in water, or mixed with powdered sugar. W.

EXTRACTUM PIPERIS FLUIDUM. *U. S. Fluid Extract of Black Pepper.*

"Take of Black Pepper, in powder, *a pound;* Ether *a sufficient quantity.* Put the powder into a percolator, and pour Ether gradually upon it until two pints of filtered liquor are obtained. From this distil off, by means of a water-bath, at a gentle heat, a pint and a half of ether, and expose the residue, in a shallow vessel, until the whole of the ether has evaporated, and the deposition of piperin in crystals has ceased. Lastly, separate the piperin by expression through a cloth, and keep the liquid portion." *U. S.*

A substance has long been in use under the name of *oil of black pepper*, which consists mainly of the volatile oil and resin of the pepper, and belongs, therefore, to the oleo-resins. As usually found it is of a thickish consistence and an almost black colour, and is a residue of the process for preparing piperin. The officinal extract has the same general character, but is of more certain strength, and should, therefore, be preferred. It contains almost all the volatile oil and acrid resin of black pepper, with little of the piperin; and as the last mentioned principle, when quite pure, is of doubtful efficacy, the extract may be considered as representing the virtues of the fruit. The colour is greener than that of the common oil of black pepper, and not so dark, owing to the circumstance that ether dissolves the green more readily than the brown colouring matter. A pound of black pepper yields about six drachms of the fluid extract, the dose of which proportionate to the ordinary dose of pepper would be one or two minims. It may be given in emulsion, or may be combined in small proportion with other substances in the form of pill. W.

EXTRACTUM RHEI FLUIDUM. *U. S. Fluid Extract of Rhubarb.*

"Take of Rhubarb, in coarse powder, *eight ounces;* Sugar *five ounces;* Tincture of Ginger *half a fluidounce;* Oil of Fennel, Oil of Anise, each, *four minims;* Diluted Alcohol *two pints*, or *a sufficient quantity.* To the Rhubarb, previously mixed with an equal bulk of coarse sand, add twelve fluidounces of Diluted Alcohol, and allow the mixture to stand for twenty-four hours. Transfer the mass to a percolator, and gradually pour upon it Diluted Alcohol until the liquid which passes has little of the odour or taste of rhubarb. Evaporate the tincture thus obtained, by means of a water-bath, to five fluidounces; then add the Sugar, and, after it is dissolved, mix thoroughly with the resulting Fluid Extract the Tincture of Ginger holding the Oils in solution." *U. S.*

This is a good preparation of rhubarb, the root being nearly exhausted by the menstruum, and the evaporation, if carefully conducted, not injuriously affecting the active principles. It is somewhat stimulant in consequence of the small proportion of alcohol present, and the addition of the volatile oils, and is not applicable, therefore, to acute inflammatory affections. For observations on this

preparation the pharmaceutical reader is referred to papers by Prof. Procter in the *American Journal of Pharmacy* (xix. 182, and xxii. 110). The process yields about eight fluidounces of the preparation, or a fluidrachm for each drachm of the rhubarb. Its purgative dose, if well made from good rhubarb, is half a fluidrachm for an adult, to be proportionably diminished for children. W.

EXTRACTUM SARSAPARILLÆ FLUIDUM. *U.S.*, *Dub.* EXTRACTUM SARSÆ LIQUIDUM. *Lond.* EXTRACTUM SARZÆ FLUIDUM. *Ed.* *Fluid Extract of Sarsaparilla.*

"Take of Sarsaparilla, sliced and bruised, *sixteen ounces;* Liquorice Root, bruised, Bark of Sassafras Root, bruised, each, *two ounces;* Mezereon, sliced, *six drachms;* Sugar *twelve ounces;* Diluted Alcohol *eight pints.* Macerate all the ingredients together, excepting the Sugar, for fourteen days; then express and filter. Evaporate the liquid, by means of a water-bath, to *twelve fluidounces;* add the Sugar to it while still hot; and remove from the bath as soon as the Sugar is dissolved." *U. S.*

"Take of Sarsa *three pounds and a half;* Distilled Water *five gallons* [Imperial measure]; Rectified Spirit *two fluidounces.* Boil the Sarsa in three gallons of the Water to twelve pints [Imp. meas.]; pour off the liquor, and strain while hot. Again boil the Sarsa in the remainder of the Water to one-half, and strain. Mix the liquors, evaporate to eighteen fluidounces, and, when the extract has cooled, mix the Spirit with it." *Lond.*

"Take of Sarza, in chips, *one pound;* Boiling Water *six pints* [Imperial measure]. Digest the root for two hours in four pints of the Water; take it out, bruise it, replace it, and boil for two hours; filter and squeeze out the liquid; boil the residuum in the remaining two pints of Water, and filter and squeeze out this liquor also; evaporate the united liquors to the consistence of thin syrup; add, when the product is cool, as much Rectified Spirit as will make in all sixteen fluidounces. Filter. This fluid extract may be aromatized with volatile oils or warm aromatics." *Ed.*

"Take of Sarsaparilla *one pound* [avoirdupois]; Boiling Water *eight pints* [Imp. meas.]; Rectified Spirit *as much as is sufficient.* Digest the Sarsaparilla in five pints of the Water for two hours, at a temperature near 212°, and then decant. Add the rest of the Water, digest again for two hours, and decant. Evaporate the mixed liquors by a steam or water heat to the consistence of a thin syrup, and, when the product has cooled, add as much Rectified Spirit as will make the entire twenty [fluid]ounces." *Dub.*

The British Colleges all prepare a simple fluid extract of sarsaparilla. That of the Dublin College is to be preferred, as the long boiling to which the other Colleges subject the root is avoided, and digestion, which experience has shown to be less injurious, is substituted. Nevertheless, the extract would probably have been more efficient, if diluted alcohol had been directed as the solvent.

The U.S. fluid extract is a compound preparation, intended to represent in a concentrated state the compound decoction of sarsaparilla, having all its ingredients with the exception of the guaiacum wood, which probably adds little to the efficacy of the decoction. The preparation was originally proposed by Wm. Hodgson, jun. (*Journ. of the Phil. Col. of Pharm.*, ii. 285); and the officinal process differs from his mainly by the omission of the guaiacum wood, the resin of which, separating during the evaporation, somewhat embarrassed the process, without adding to the virtues of the extract. We greatly prefer this fluid extract to that of the British Colleges. If the effects of a simple extract of sarsaparilla are desired, they can be obtained by having recourse to the solid officinal extract of the U.S. Pharmacopœia. The dose is a fluidrachm, equivalent to a drachm of the root, three or four times a day. W.

EXTRACTUM SENNÆ FLUIDUM. *U. S.* *Fluid Extract of Senna.*

"Take of Senna, in coarse powder, *two pounds and a half;* Sugar *twenty ounces;* Oil of Fennel *a fluidrachm;* Compound Spirit of Ether *two fluidrachms;* Diluted Alcohol *four pints.* Mix the Senna with the Diluted Alcohol, and, having allowed the mixture to stand for twenty-four hours, introduce it into a percolator, and gradually pour in water mixed with one-third of its bulk of alcohol, until a gallon and a half of liquid shall have passed. Evaporate the liquid by means of a water-bath to twenty fluidounces, filter, then add the Sugar, and, when it is dissolved, the Compound Spirit of Ether holding the Oil of Fennel in solution." *U. S.*

This preparation was originally suggested by Mr. Charles Ellis, of Philadelphia, subsequently modified by the late Mr. Duhamel, of the same place, and adopted by the framers of the U. S. Pharmacopœia. The use of the compound spirit of ether is to prevent fermentation. A fluid extract is largely prepared in England by evaporating the infusion of senna in vacuo. For a formula by Mr. Duncan, of Edinburgh, see the *Medical Examiner* (vi. 250). The dose of the U. S. fluid extract is half a fluidounce for an adult. W.

EXTRACTUM SPIGELIÆ ET SENNÆ FLUIDUM. *U. S.* *Fluid Extract of Spigelia and Senna.*

"Take of Pinkroot, in coarse powder, *a pound;* Senna, in coarse powder, *six ounces;* Sugar *a pound and a half;* Carbonate of Potassa *six drachms;* Oil of Caraway, Oil of Anise, each, *half a fluidrachm;* Diluted Alcohol *a sufficient quantity.* Mix the Pinkroot and Senna with two pints of Diluted Alcohol, and, having allowed the mixture to stand for two days, transfer it to a percolator, and gradually pour upon it Diluted Alcohol until half a gallon of liquid has passed. Evaporate the liquid, by means of a water-bath, to a pint; then add the Carbonate of Potassa, and, after the sediment has dissolved, the Sugar previously triturated with the Oils. Lastly, dissolve the Sugar with a gentle heat." *U. S.*

This fluid extract combines the cathartic property of senna with the anthelmintic virtues of pinkroot, and is a very good vermifuge, being generally acceptable to the stomach, and, what is of no little importance in such medicines, not offensive to the taste. It has been in use in Philadelphia for several years, and with satisfactory results. The use of the carbonate of potassa is to enable the resinous matter which is deposited during evaporation to be dissolved, and also to counteract the griping property of the senna. The whole product of the process should be about a pint and a half. The dose is half a fluidounce for an adult, a fluidrachm for a child two years old. W.

EXTRACTUM VALERIANÆ FLUIDUM. *U.S.* *Fluid Extract of Valerian.*

"Take of Valerian, in coarse powder, *eight ounces;* Ether *four fluidounces;* Alcohol *twelve fluidounces;* Diluted Alcohol *a sufficient quantity.* Mix the Ether and Alcohol, and, having incorporated the Valerian with one half of the mixture, introduce the mass into a percolator, and gradually pour in the remainder. Then add Diluted Alcohol until the whole liquid which has passed shall amount to a pint. Put the ethereal liquid thus obtained into a shallow vessel, and allow it to evaporate spontaneously until reduced to five fluidounces. Upon the mass in the percolator pour gradually Diluted Alcohol until ten fluidounces of tincture have passed. With this mix the five fluidounces left after the spontaneous evaporation, taking care to dissolve in a little alcohol any oleoresinous matter which may have been deposited, and to add it to the rest. Allow the mixture to stand, with occasional agitation, for four hours, and then filter.

The resulting Fluid Extract should measure a pint; and, if it be less than that quantity, the deficiency should be supplied by the addition of Alcohol." *U. S.*

This is a preparation representing in a concentrated state the virtues of valerian, and may be used when the influence of that medicine is desired. (See papers by Mr. Evan T. Ellis in the *American Journal of Pharmacy*, xix. 83, and by Prof. Procter, *ibid.*, 184.) The dose is one or two fluidrachms. W.

FERRUM.

Preparations of Iron.

FERRI PULVIS. *U. S., Dub. Powder of Iron. Reduced Iron. Iron by Hydrogen. Quevenne's Iron.*

Take of Subcarbonate of Iron, previously calcined in an open vessel, *two pounds and a half*, or *a convenient quantity*. Into a wrought iron reduction tube, of about four inches in diameter, introduce the Subcarbonate, contained in an incomplete sheet-iron tube, open at both ends, made by bending the iron into the form of a cylinder, and of such a size as to fill loosely about seven-eighths of the reduction tube. Place the reduction tube longitudinally in an oblong charcoal furnace; and, by means of a self-regulating generator of hydrogen, pass through it a stream of that gas, previously purified by bubbling successively through Solution of Subacetate of Lead, diluted with three times its volume of water, and through milk of lime, severally contained in half-gallon bottles, about one-third filled. Connect with the further extremity of the reduction tube a lead tube bent so as to dip into water. Make all the junctions air-tight by appropriate lutes; and, when the hydrogen has passed long enough to fill the whole of the apparatus, to the exclusion of atmospheric air, light the fire, and bring that part of the reduction tube occupied by the Subcarbonate to a dull red heat, which must be kept up so long as the bubbles of hydrogen, breaking from the water covering the orifice of the lead tube, are smaller than those passing through the milk of lime. When the reduction is completed, remove the fire, and allow the whole to cool to the ordinary temperature, keeping up, during the refrigeration, a moderate current of hydrogen through the apparatus. Lastly, withdraw the reduced iron from the reduction tube, detach it from the sheet-iron tube, and, having powdered it, keep it in well-stopped bottles. When two pounds and a half of Subcarbonate of Iron are operated on, the process occupies from five to eight hours." *U. S.*

"Take of Peroxide of Iron, Zinc, in small pieces, Oil of Vitriol, Water, each, *a sufficient quantity*. Introduce into a gun-barrel as much of the Peroxide of Iron as will occupy the length of about ten inches, confining it to the middle portion of the barrel by plugs of asbestos. Let the gun-barrel be now placed in such a furnace as is used for organic analysis, one end of it being fitted by means of a cork into a bent adapter whose further extremity dips in water, while the other end (of barrel) is connected with a bottle containing the Zinc and Water, with the intervention, however, of a desiccating tube including fragments of caustic potash, and a small bottle half filled with oil of vitriol. Matters being thus arranged, a little Oil of Vitriol is to be poured into the bottle containing the Water and Zinc, with the view of developing a sufficiency of hydrogen to expel the air from the interior of the apparatus. As soon as this object is considered to have been accomplished, the part of the tube containing the Peroxide of Iron must be surrounded with ignited charcoal, and, when it is thus brought to a low red heat, the Oil of Vitriol is to be gradually added to the Zinc, so as to cause a steady current of hydrogen to pass through the oil of vitriol and de-

siccation tube into the gun-barrel. As soon as the reduction of the Oxide is completed, which may be judged to have taken place when the gas bubbles escape at apparently the same rate through the water in which the adapter terminates, and through the bottle containing the oil of vitriol, the fire is to be removed (a slow current of hydrogen being still continued), and when the gun-barrel has assumed the temperature of the air its metallic contents should be extracted, and preserved in an accurately stopped bottle." *Dub.*

This is a new preparation of the U. S. and Dublin Pharmacopœias of 1850, and consists of metallic iron in fine powder, obtained by reducing the sesquioxide by hydrogen at a dull-red heat. The subcarbonate of the U. S. Pharmacopœia, which is essentially the sesquioxide of iron, is deprived of water by calcination, and then subjected to the reducing influence of a stream of hydrogen, purified from sulphuretted hydrogen and acid by passing successively through a solution of subacetate of lead and milk of lime. The hydrogen unites with the oxygen of the sesquioxide to form water, and leaves the iron in the metallic state. The subcarbonate should be perfectly free from sulphate of soda, which it is apt to contain when imperfectly washed. If this salt be present it will be reduced by the hydrogen to the state of sulphuret of sodium, which will contaminate and spoil the metallic iron formed. The heat should be carefully regulated; for if it fall below dull redness, part of the oxide will escape reduction; and if it exceed that point considerably, the particles of reduced iron will agglutinate, and not be readily pulverizable. The Dublin process is not so well fitted for practical purposes as that of the U. S. Pharmacopœia. The directions given in the Dublin formula to dry the hydrogen are unnecessary. On the subject of powder of iron, manufacturing chemists will find it useful to consult the paper of MM. Soubeiran and Dublanc, in which full directions are given for purifying the hydrogen, constructing the furnace, regulating the heat, and avoiding explosions. (*Amer. Journ. of Pharm.*, xviii. 303, from the *Journ. de Pharm.*, viii. 187.) Prof. Procter, of Philadelphia, has made some improvements in the process of Soubeiran and Dublanc, which he has communicated in a paper, embracing many useful details. (*Amer. Journ. of Pharm.*, xix. 11.)

Properties. Powder of iron is tasteless, and of an iron-gray colour. If black the preparation is to be rejected as not being fully deoxidized. When thrown into a dilute acid, it causes a lively effervescence of hydrogen. A small portion of it, struck on an anvil with a smooth hammer, forms a scale, having a brilliant metallic lustre. On account of its great liability to oxidation, it should be kept in a dry bottle, well stopped. A black powder, having a composition corresponding with that of the magnetic oxide of iron, has been recently sold in London and Edinburgh under the name of Quevenne's iron. (See the *Pharm. Journ. and Trans.* for Jan., Feb., and March, 1854.) The spurious powder may be known by its having a black instead of an iron-gray colour, and by its effervescing but slightly with acids. In the process for making reduced iron, part of the sesquioxide almost always escapes full deoxidation, and comes out of the tube of a black colour. This part should be rejected, instead of being sold as reduced iron, as appears to have been done by some London manufacturing chemists.

Medical Properties. Powder of iron, reduced from the oxide by hydrogen, was first prepared for medicinal purposes by MM. Quevenne and Miquelard, of Paris. It has been used by Raciborski and other physicians in anæmia, and, generally, in those diseases characterized by a deficiency of colouring matter in the blood. In two cases of enlarged spleen, following intermittent fever in anemic subjects, M. Coste found it to act with remarkable efficacy. In view of the peculiar state of aggregation of its particles, this preparation is undoubtedly the best form of metallic iron for medicinal use. The dose is from three to six grains several times a day, given in powder or pill. B.

TINCTURA FERRI ACETATIS. *Dub.* *Tincture of Acetate of Iron.*

"Take of Sulphate of Iron *eight ounces* [avoirdupois]; Distilled Water *half a pint* [Imperial measure]; Pure Sulphuric Acid *six fluidrachms* [Imp. meas.]; Pure Nitric Acid *half a fluidounce* [Imp. meas.]; Acetate of Potash *eight ounces* [avoird.]; Rectified Spirit *half a gallon* [Imp. meas.]. To nine [fluid]ounces of the Water add the Sulphuric Acid, and in the mixture, with the aid of heat, dissolve the Sulphate of Iron. Add next the Nitric Acid, first diluted with the remaining [fluid]ounce of Water, and evaporate the resulting solution to the consistence of a thick syrup. Dissolve this in one quart [two pints, Imp. meas.], and the Acetate of Potash in the remainder of the Spirit, and, having mixed the solutions, and shaken the mixture repeatedly in a large bottle, let the whole be thrown upon a calico filter. When any further liquid ceases to trickle through, subject the filter, with its contents, to expression, and, having cleared the turbid tincture thus procured by filtration through paper, let it be added to that already obtained. The sp. gr. of this tincture is 0·891." *Dub.*

This preparation is a tincture of the teracetate of sesquioxide of iron. The first step in making it is to convert the sulphate of protoxide of iron into the tersulphate of the sesquioxide by the action of sulphuric and nitric acids, with the aid of heat, in the usual way. The salt thus formed is then dissolved in half the rectified spirit, the acetate of potassa in the other half. The spirituous saline solutions having been mixed, a double decomposition of the salts takes place, resulting in the formation of teracetate of sesquioxide of iron which dissolves in the spirit, and sulphate of potassa which precipitates, being insoluble in that menstruum. By filtration, therefore, the sulphate of potassa is removed, and the clear liquid constitutes the tincture under notice. As there is an excess of sulphate of protoxide of iron taken, the tersulphate of the sesquioxide into which it is converted, is more than sufficient to decompose all the acetate of potassa. Accordingly, the portion of the tersulphate not expended in the double decomposition, being soluble in rectified spirit, remains in solution along with the teracetate in the tincture.

Properties. This tincture is a transparent liquid, of a deep-red colour, and strong chalybeate taste. It is said to form an agreeable chalybeate. The dose is from twenty drops to a teaspoonful, sufficiently diluted with water. B.

FERRI CARBONAS SACCHARATUM. *Ed.*, *Dub.*; FERRI CARBONAS CUM SACCHARO. *Lond.* *Saccharine Carbonate of Iron. Carbonate of Iron with Sugar.*

"Take of Sulphate of Iron *four ounces;* Carbonate of Soda *four ounces and a quarter;* Sugar *two ounces*; boiling Distilled Water *four pints* [Imp. meas.]. Dissolve separately the Sulphate and Carbonate in two pints of the Water. Mix the solutions while still hot, and set the mixture by that the Carbonate of Iron may subside. Then, having poured off the supernatant liquor, wash frequently the precipitated Carbonate. To this add the Sugar, dissolved in two fluidounces of Water, and evaporate the mixture by means of a water-bath until the powder is dry. Keep this in a well stopped bottle." *Lond.*

"Take of Sulphate of Iron *four ounces;* Carbonate of Soda *five ounces;* Pure Sugar *two ounces;* Water *four pints* [Imp. meas.]. Dissolve the Sulphate and Carbonate, each, in two pints of the water; add the solutions and mix them; collect the precipitate on a cloth filter, and immediately wash it with cold water, squeeze out as much of the water as possible, and without delay triturate the pulp which remains with the Sugar previously in fine powder. Dry the mixture at a temperature not much above 120°." *Ed.*

The Dublin process is substantially the same as the Edinburgh, and, therefore, need not be given.

When solutions of sulphate of iron and carbonate of soda are mixed together, there are formed, by double decomposition, sulphate of soda which remains in solution, and carbonate of protoxide of iron which falls as a pale-bluish precipitate. This precipitate begins immediately to alter in nature by the absorption of oxygen, and, if washed and dried in the ordinary way, becomes sesquioxide of iron, associated with a small quantity of the carbonate of the protoxide which has escaped change; in other words, it is converted into the subcarbonate of iron of the U. S. Pharmacopœia. (See *Ferri Subcarbonas.*) As the preparations of iron containing the protoxide are most esteemed, the change which this precipitate undergoes was always matter of regret, and various attempts were made to prevent it. Now saccharine matter has been ascertained to possess the property of preventing this change; and, in the preparation under consideration, its power is brought into play of preventing the protoxide of iron of the carbonate as first precipitated from passing into sesquioxide, with loss of carbonic acid.

Dr. Becker, a German physician, was the first to suggest the use of saccharine matter as a means of protection against the absorption of oxygen; and the idea was carried out by Klauer, a German chemist, who first made the saccharine carbonate of iron. In the London process the washed precipitate is immediately mixed with the sugar in the form of syrup. In the Edinburgh formula, it is pressed so as to free it from water as far as possible, and then incorporated with the sugar in fine powder. The mode of treating the precipitate, directed in the London formula, is that recommended by Mr. R. Phillips, jun., and is preferable to the treatment by expression, which exposes it for a longer period to the action of the air. The final drying heat should not exceed 130°. The protection from oxidation, however, is more complete, when both the materials and product of the process are maintained constantly in contact with saccharine matter, by using weak syrup both for dissolving the salts and for washing the precipitate, after the improved method of Vallet, of Paris. This improved method of proceeding is adopted for forming the U. S. pills of carbonate of iron, or Vallet's ferruginous pills. (See *Pilulæ Ferri Carbonatis, U. S.*)

Properties. Saccharine carbonate of iron is a grayish-green powder, permanent in the air, having a sweetish, styptic taste, and wholly and readily soluble in muriatic acid, with brisk effervescence. Its composition is not well made out. The Edinburgh College defines it to be a "carbonate of protoxide of iron in an undetermined state of combination with sugar and sesquioxide of iron." The presence of sesquioxide of iron is a defect, which is avoided in Vallet's ferruginous pills.

Medical Properties. This preparation is an excellent chalybeate, possessing the advantages of having nearly all the iron in it in the state of protoxide, and of being readily soluble in acids. Originally introduced into the officinal list by the Edinburgh College, it appears for the first time in the Dublin and London Pharmacopœias of 1850 and 1851. It is probably more active than the subcarbonate of iron, and must be used in a smaller dose. It is, however, inferior to Vallet's ferruginous mass, in the preparation of which the anti-oxidizing influence of saccharine matter is more fully applied. The dose of the saccharine carbonate of iron is from five to thirty grains, given in the form of pill.

Off. Prep. Pilulæ Ferri Carbonatis, *Ed.* B.

TINCTURA FERRI CHLORIDI. *U. S.* Tinctura Ferri Sesquichloridi. *Lond., Dub.* Ferri Muriatis Tinctura. *Ed. Tincture of Chloride of Iron. Tincture of Muriate of Iron.*

"Take of Subcarbonate of Iron *half a pound;* Muriatic Acid *a pint;* Alcohol *three pints.* Pour the Acid upon the Subcarbonate of Iron, in a glass or porcelain vessel, mix them, and, when effervescence has ceased, apply a gentle heat,

and continue it, stirring occasionally, until the carbonate is dissolved; then filter the solution, and mix it with the alcohol." *U. S.*

"Take of Sesquioxide of Iron [Subcarbonate, *U. S.*] *six ounces;* Hydrochloric Acid *a pint* [Imperial measure]; Rectified Spirit *three pints* [Imp. meas.]. Mix the Sesquioxide with the Acid, and digest with a sand-bath, occasionally stirring, till it is dissolved. Then to the solution, after it has cooled, add the Spirit, and filter." *Lond.*

"Take of Red Oxide [Subcarbonate] of Iron *six ounces;* Muriatic Acid (commercial) *one pint* [Imp. meas.]; Rectified Spirit *three pints* [Imp. meas.]. Add the Oxide to the Acid in a glass vessel; digest with a gentle heat, and occasional agitation, for a day, or till most of the Oxide be dissolved; then add the Spirit, and filter." *Ed.*

"Take of Iron Wire *eight ounces* [avoirdupois]; Pure Muriatic Acid *one quart* [two pints, Imp. meas.]; Pure Nitric Acid *eighteen fluidrachms* [Imp. meas.]; Distilled Water *one pint* [Imp. meas.]; Rectified Spirit *one pint and a half* [Imp. meas.]. Dilute the Muriatic Acid with the Water, and, having poured the mixture on the Iron, apply a gentle heat till the metal is dissolved. Next add the Nitric Acid in successive portions, and then evaporate at a gentle heat until the solution is reduced to one pint. Finally mix this in a bottle with the Spirit, and, after the mixture has stood for twelve hours, draw off the clear tincture. The sp. gr. of this tincture is 1·237." *Dub.*

The subcarbonate of iron of the shops consists of sesquioxide of iron, mixed with a variable, but always small proportion of carbonate of the protoxide. When acted on by muriatic acid it dissolves with effervescence, in consequence of the escape of carbonic acid; and a solution of the sesquichloride of iron, with a little protochloride, is obtained. When the muriatic acid employed is of the officinal strength (sp. gr. 1·16), the quantity directed in the U. S. formula dissolves nearly all the subcarbonate, leaving behind, according to Mr. Phillips, less than one scruple, including accidental impurities. A reaction appears to take place between the muriatic acid and the alcohol, as the preparation has a decided ethereal odour. On exposure, the small quantity of protochloride of iron present is converted, by the absorption of oxygen, into sesquichloride and sesquioxide, the latter of which is precipitated unless there be an excess of muriatic acid present. In the U. S. formula no such excess exists, and the tincture may consequently deposit, upon standing, a little sesquioxide of iron, and become in the same proportion more feeble; but this is a very slight objection, and is easily obviated, if thought advisable, by adding sufficient muriatic acid to redissolve the precipitate. The London and Edinburgh preparations, which have a considerable excess of acid, are liable to the more serious objection of being thus rendered more irritant to the stomach. It is important that the apothecary should employ muriatic acid of the officinal specific gravity, as otherwise his preparation will be of uncertain strength. A want of attention to this circumstance is probably the cause that the tincture, as found in the shops, is very unequal. Of four specimens examined by Mr. Phillips, one yielded from half a fluidounce 20 grains of sesquioxide of iron, another 12·1 grains, a third 11·3 grains, and the fourth only 9·3 grains. A specimen prepared by himself, precisely according to the directions of the London Pharmacopœia of 1824, which are at present those of our own national standard, had the sp. gr. 0·994, and yielded, from half a fluidounce, 16·8 grains of sesquioxide. The present London preparation, according to the same authority, has the sp. gr. 0·992, and would afford, from half a fluidounce, upon the addition of potassa, nearly 15 grains of sesquioxide. The process of the Dublin Pharmacopœia of 1850 is quite new. In the first step of it a solution of protochloride of iron is formed, which is subsequently converted by the reaction of nitric acid into a solution of the sesquichloride, to which the

alcohol is added. The strength of the resulting tincture is more than thrice that of the other British preparations, and nearly thrice that of the U. S. tincture.

Properties. Tincture of chloride of iron is of a reddish-brown, somewhat yellowish colour, a sour and very styptic taste, and an odour resembling that of muriatic ether. The sesquichloride of iron, which results from its evaporation, is a deliquescent compound, of a dark-orange colour, scarcely crystallizable, and consisting of two eqs. of iron 56, and three of chlorine 106·26=162·26. The tincture is decomposed by the alkalies, alkaline earths and their carbonates, astringent vegetable infusions, and the mucilage of gum Arabic, which produces with it a brown semi-transparent jelly. All these substances are, therefore, incompatible with it in prescriptions.*

Medical Properties and Uses. This is one of the most active and certain preparations of iron, usually acceptable to the stomach, and much employed for the purposes to which the chalybeates generally are applied. It has been particularly commended as a tonic in scrofula, in which it was formerly often given, jointly with the solution of chloride of calcium, or chloride of barium. It is supposed to be diuretic, and to have a peculiar influence on the urinary passages. Hence it has been employed in gleet, old gonorrhœa, and leucorrhœa; and is said to be useful in dysury dependent on spasmodic stricture of the urethra, in the dose of ten drops repeated every ten minutes, till some effect is experienced. In hemorrhages from the uterus, kidneys, and bladder, it is thought to act advantageously, but should be confined to those of a passive character, or employed only after sufficient depletion. Externally it is sometimes used for the destruction of venereal warts, and as a styptic in cancerous and fungous ulcers. It has recently been employed with success, as an injection in aneurismal tumours. (See *Ranking's Abstract*, xviii. 120.) The dose of the U. S. tincture is from ten to thirty minims, which may be gradually increased to one or even two fluidrachms, two or three times a day. It is given diluted with water. W.

FERRI CITRAS. *U. S. Citrate of Iron.*

"Take of Citric Acid *five ounces and a half;* Sulphate of Iron *twelve ounces;* Distilled Water *five fluidounces.* Dissolve the Acid in the Water. Then prepare from the Sulphate the Hydrated Oxide of Iron, according to the formula for that substance. To the solution of the Acid, heated to about 150°, and maintained at that temperature, gradually add the Hydrated Oxide, in its moist and recent state, as long as it is dissolved, and until the Acid is fully saturated. Filter the liquid, and, having evaporated it to the consistence of a thick syrup, spread it in layers on glass or porcelain plates, so that, when dried, it may form thin laminæ, which are to be detached from the plates, and broken into pieces of convenient size." *U. S.*

In this process a strong solution of citric acid, heated to 150°, is accurately saturated with moist and recent hydrated sesquioxide of iron. The heat directed promotes the solution of the sesquioxide; but a boiling temperature is to be avoided, as it renders the oxide less readily soluble. Citrate of iron, as thus prepared, is in thin transparent pieces, of a beautiful garnet-red colour. It is an uncrystallizable acid salt, slowly soluble in cold, but readily soluble in boil-

* *Bestucheff's tincture*, which is much used in Europe, is simply a solution of sesquichloride of iron in a mixture of one measure of ether and three or four measures of alcohol. Fr. Mayer recommends that the sesquichloride should be prepared by passing chlorine through a solution of the protochloride, until a solution of the red ferrocyanuret of potassium no longer produces a blue precipitate, and then evaporating by a water-bath. In this mode crystals of the sesquichloride are obtained, one ounce of which is to be dissolved in twelve ounces of ether, mixed with four times its bulk of alcohol. The solution may be rendered colourless, if desired, by exposure to the direct rays of the sun. (*N. Y. Journ. of Pharm.*, i. 233.)

ing water, and possessing a mild chalybeate taste. It consists of one eq. of citric acid 165, and one of sesquioxide of iron 80=245.

Citrate of iron was introduced to the notice of the profession, in 1831, by M. Béral, of Paris. It is a pleasant chalybeate, and is best given in the form of pill. The dose is five grains, repeated several times a day. B.

FERRI AMMONIO-CITRAS. *Lond., Dub. Ammonio-citrate of Iron.*

"Take of Sulphate of Iron *twelve ounces;* Carbonate of Soda *twelve ounces and a half;* Citric Acid *six ounces;* Solution of Ammonia *nine fluidounces* [Imp. meas.]; boiling Distilled Water *twelve pints* [Imp. meas.]. Dissolve separately the Sulphate and Carbonate in six pints of the Water. Mix the solutions while still hot, and set the mixture by that the precipitate may subside. Having poured off the supernatant liquor, wash the precipitate frequently with water, throw in the Acid, and dissolve by the aid of heat. When the solution has cooled, add the Ammonia, and evaporate to the consistence of syrup. Pour this in thin layers on earthenware plates, dry with a gentle heat, and preserve the product in a well stopped bottle." *Lond.*

The *Dublin College* dissolves its hydrated peroxide of iron, freshly made, in a solution of citric acid, and boils for twenty minutes. The cool solution, after the addition of ammonia in slight excess, is dried in thin layers, so as to form scales.

In the London process, by double decomposition between sulphate of iron and carbonate of soda, carbonate of protoxide of iron is first formed, which, by the exposure to the air during washing, becomes the sesquioxide with loss of carbonic acid. To this oxide, while still moist, the citric acid is added, and the whole is dissolved by the aid of heat, the moisture present and the water of crystallization of the acid being sufficient to effect the solution. In this manner the citrate of sesquioxide of iron is formed, the salt described in the last article. Now this is an acid salt, and when the excess of acid in it is neutralized with ammonia, the ammonio-citrate of iron is formed, from which the greater part of the ammonia is driven off when dried with a gentle heat.

Properties, &c. Ammonio-citrate of iron is in garnet-red scales, having a slightly chalybeate taste, and forming a solution of a clear ruby colour. It is much more readily soluble in water than the citrate of iron described in the last article. It is neutral to test paper, and not rendered blue by the addition of ferrocyanuret of potassium. It is decomposed by potassa and lime-water, which throw down sesquioxide of iron and evolve ammonia. The London College states that 100 grains of the salt, dissolved in water and treated with potassa, yield about 34 grains of sesquioxide of iron. This salt forms a pleasant chalybeate. Its ready solubility gives it an advantage over the citrate. The dose is five grains, repeated several times a day, and given in solution. According to Dr. Paris it may be united with the carbonated alkalies without decomposition, and given in a state of effervescence with citric acid. B.

FERRI ET POTASSÆ TARTRAS. *U. S.* FERRI POTASSIO-TARTRAS. *Lond.* FERRUM TARTARIZATUM. *Ed., Dub. Tartrate of Iron and Potassa. Tartarized Iron.*

"Take of Sulphate of Iron *eight ounces;* Bitartrate of Potassa *seven ounces;* Distilled Water *half a gallon.* Prepare from the Sulphate the Hydrated Oxide of Iron, according to the formula for that substance. Mix the Bitartrate of Potassa with the Distilled Water, heat the mixture to 140°, and, keeping it at that temperature, add gradually the Hydrated Oxide, frequently stirring, until it ceases to be dissolved. Then filter the solution, evaporate it by means of a water-bath to the consistence of Syrup, and spread it upon plates of glass or porcelain, so that it may dry in the form of scales." *U. S.*

"Take of Sulphate of Iron *four ounces;* Sulphuric Acid *half a fluidounce;* [Imp. meas.]; Nitric Acid *a fluidounce* [Imp. meas.]; Solution of Ammonia *ten fluidounces* [Imp. meas.]; Bitartrate of Potassa, powdered, *two ounces;* Distilled Water *four gallons* [Imp. meas.]. Dissolve the Sulphate with the Sulphuric Acid in a pint of the Water; then, applying heat, add gradually the Nitric Acid. Boil down the solution to the consistence of syrup, and mix it with the rest of the Water. Then add the Ammonia, in order to throw down the sesquioxide of iron. Wash this and set it aside for twenty-four hours. Then heat the Bitartrate, mixed with half a pint of Distilled Water, to 140°, and to this mixture add the moist sesquioxide, the water which floats over it having been poured off. Separate the part of the sesquioxide which fails to be dissolved by straining through a cloth; then evaporate the clear liquor until the salt is dry. The Potassio-tartrate of Iron may also be dried in the manner directed for Ammonio-citrate of Iron." *Lond.*

"Take of Sulphate of Iron *five ounces;* Bitartrate of Potash *five ounces and one drachm;* Carbonate of Ammonia, in fine powder, *a sufficiency.* Prepare the Rust of Iron from the Sulphate as directed under Ferrugo, and without drying it. Mix the pulpy mass with four pints [Imp. meas.] of Water; add the Bitartrate; boil till the Rust of Iron is dissolved; let the solution cool; pour off the clear liquid, and add to this the Carbonate of Ammonia so long as it occasions effervescence. Concentrate the liquid over the vapour-bath to the consistence of a thick extract, or till the residuum becomes on cooling a firm solid, which must be preserved in well-closed vessels." *Ed.*

"Take of Sulphate of Iron *eight ounces* [avoirdupois]; white Bitartrate of Potash *five ounces* [avoird.]; Distilled Water *one pint and a half* [Imp. meas.]. From the Sulphate of Iron prepare Hydrated Peroxide of Iron by the [Dublin] process, and having, immediately after it is washed, placed it with the Bitartrate of Potash and Water in a porcelain capsule, apply heat to the mixture (taking care, however, that the temperature does not rise beyond 150°), and stir it occasionally for six hours. Let the solution, after it has cooled down to the temperature of the atmosphere, be decanted off any undissolved oxide of iron, and, having transferred it in small quantities to delf dinner plates, let it be evaporated to dryness at a heat not exceeding 150°. Lastly, chip off the film of dry salt which adheres to the plates, and preserve it in well stopped bottles." *Dub.*

The object of these processes is to combine the excess of acid in the bitartrate of potassa with sesquioxide of iron. In all of them the plan of Soubeiran is adopted; namely, that of dissolving the moist hydrated sesquioxide to saturation in a mixture of the bitartrate and water, aided by a moderate heat. The sesquioxide is now obtained, in all the Pharmacopœias, from the tersulphate of sesquioxide of iron, which is precipitated either by ammonia (*U.S., Lond., Ed.*), or by solution of potassa (*Dub.*). Potassa is not a good precipitant; because the alkali adheres obstinately to the precipitated sesquioxide, and cannot be completely separated even by repeated washings. The necessary hydrated sesquioxide is made in the body of the London formula; this College not having it as the product of a separate process. The sesquioxide should be gradually added to the bitartrate and water, heated to 140°, as recommended by Soubeiran, at which temperature the oxide dissolves more readily and in larger quantity than when ebullition is employed. In the U.S. and Dublin formulæ, the liquid is poured out on a plane surface, so as to dry in scales; and the London College gives this as an alternative method of drying. The present formulæ of the U.S., London, and Dublin Pharmacopœias are much superior to those of former editions of those works.

Dr. Ure has proposed the *tartrate of protoxide of iron* for medical use. He makes it by acting on clean iron filings, or bits of iron wire, with a solution o

tartaric acid. It is a pulverulent salt, insoluble in water, and possessing a mild chalybeate taste.

Properties. Tartrate of iron and potassa, as obtained by the U. S and Dublin formulæ, is in transparent scales of a ruby-red colour, and wholly soluble in about four parts of water. It has a slightly chalybeate taste. Its solution does not change the colour of litmus, and at common temperatures is not precipitated by potassa, soda, or ammonia. Ferrocyanuret of potassium does not render it blue, unless an acid be added. The non-action of this test shows that the iron is in a peculiar state of combination. It is incompatible with astringent vegetable infusions, which give rise to a dark-coloured precipitate. When heated with potassa, 100 grains of the salt yield a precipitate of about 34 grains of sesquioxide of iron. (*Lond. Pharm.* 1851.)

Composition. Prepared according to the U. S., London, or Dublin formula, it consists of one eq. of tartrate of sesquioxide of iron, and one of tartrate of potassa. When of this composition it contains 34 per cent. of sesquioxide of iron. The Edinburgh preparation contains only about 18 per cent. of sesquioxide.

Medical Properties. Tartrate of iron and potassa is an agreeable chalybeate, and, when made according to the U. S., London, or Dublin formula, may be depended upon for activity and uniformity of composition. From its slight taste and ready solubility, it is one of the best ferruginous preparations for children. The dose for an adult is from ten grains to half a drachm, given in solution, or combined with an aromatic or bitter in the form of bolus. B.

FERRI FERROCYANURETUM. *U.S.* *Ferrocyanuret of Iron. Pure Prussian Blue.*

"Take of Sulphate of Iron *four ounces;* Sulphuric Acid *three fluidrachms and a half;* Nitric Acid *six fluidrachms,* or *a sufficient quantity;* Ferrocyanuret of Potassium *four ounces and a half;* Water *two pints.* Dissolve the Sulphate of Iron in a pint of the Water, and, having added the Sulphuric Acid, boil the solution. Pour into it the Nitric Acid, in small portions, boiling the liquid for a minute or two after each addition, until a dark colour is no longer produced; then allow it to cool. Dissolve the Ferrocyanuret of Potassium in the remainder of the Water, and add this solution gradually to the first liquid, agitating the mixture after each addition; then pour it upon a filter. Wash the precipitate with boiling water, until the washings pass tasteless. Lastly, dry it and rub it into powder." *U. S.*

In the process above given, the sulphate of protoxide of iron in solution is first acidulated with sulphuric acid, and then converted into the tersulphate of the sesquioxide by means of nitric acid. The object of the addition of the sulphuric acid, is to provide for the higher saturating power of the sesquioxide over the protoxide, and thus to prevent the precipitation of the subsulphate of the sesquioxide. The tersulphate of the sesquioxide may be obtained, without the use of nitric acid, by treating the sulphate of the protoxide, previously dried, with boiling sulphuric acid. (Levol, *Journ. de Pharm.*, xviii. 343.) The tersulphate is then decomposed by the gradual addition of the solution of ferrocyanuret of potassium. Three eqs. of ferrocyanuret, and two of tersulphate of sesquioxide of iron, are mutually decomposed, with the result of forming one eq. of Prussian blue, or the 3–4 ferrocyanuret of iron, which precipitates, and six. eqs. of sulphate of potassa, which remain in solution. Ferrocyanogen is a tercyanuret of iron ($FeCy_3$); and, representing it by its symbol Cfy, we may compactly express the above reaction by the following equation; $3CfyK_3$ and $2(Fe_2O_3,3SO_3)=3Cfy,4Fe$ and $6(KO,SO_3)$. Prussian blue contains the elements of six eqs. of water, which cannot be separated without the destruction of the compound. Adding these elements, we may suppose it to become a hydroferrocyanate of the sesquioxide of iron, represented by the formula, $3CfyH_6$

Fe_4O_6. From the formula given for the anhydrous compound (3Cfy,4Fe), it is evident that it contains nine eqs. of cyanogen and seven of iron.

Preparation for Use in the Arts. Prussian blue is manufactured on the large scale as follows. A mixture made of equal parts of carbonate of potassa (pearl-ash of commerce), and animal matter, such as dried blood, hair, the shavings of horn, &c., is calcined at a red heat in an iron vessel, until it becomes pasty. The mass, when cold, is thrown, by portions at a time, into twelve or fifteen times its weight of water, with which it is stirred for half an hour. The whole is then put upon a linen filter; and the clear solution obtained is precipitated by a mixed solution of two parts of alum and one of the sulphate of protoxide of iron. An effervescence occurs, due principally to carbonic acid; and a very abundant precipitate is thrown down, of a blackish-brown colour. This precipitate is washed, by decantation, by means of a large quantity of water, which is renewed every twelve hours. By these washings, which last from twenty to twenty-five days, the precipitate becomes, successively, greenish-brown, bluish, and finally deep-blue. When of the latter colour, it is collected and allowed to drain upon a cloth, after which it is divided into cubical masses and dried.

Properties. Pure Prussian blue is a tasteless powder, insoluble in water and alcohol, and having a rich deep-blue colour. It is insoluble in dilute acids, decomposed by fuming nitric acid, and dissolved without decomposition by strong sulphuric acid, forming a white mass of the consistence of paste, from which the Prussian blue may be precipitated unchanged by water. Concentrated muriatic acid decomposes it, dissolving sesquioxide of iron, and liberating hydroferrocyanic acid. Boiled with red oxide of mercury it generates bicyanuret of mercury. (See *Hydrargyri Cyanuretum.*) By the contact of a red-hot body it takes fire and burns slowly, leaving a residue of sesquioxide of iron. When it is heated in close vessels, water, hydrocyanic acid, and carbonate of ammonia are evolved, and carburet of iron is left. Its composition has been given above. The Prussian blue of commerce was discovered by accident, in 1710, by Diesbach, a preparer of colours at Berlin. It has the same general properties as the pure substance. It occurs in small rectangular masses, which are heavier than water, and have a fracture presenting a bronzed appearance. Besides the constituents of pure Prussian blue, it always contains alumina, derived from the alum employed in its manufacture, and which serves to give it body as a pigment, and uncombined sesquioxide of iron. These substances may be detected by boiling the pigment with dilute muriatic acid, and precipitating the filtered solution with ammonia. Pure Prussian blue, treated in this manner, yields no precipitate.

Medical Properties, &c. Prussian blue is supposed to act as a tonic, febrifuge, and alterative. Dr. Zollickoffer, of Maryland, has recommended it as a remedy in intermittent and remittent fevers, and deems it to be particularly adapted to such cases occurring in children, on account of the smallness of the dose and its want of taste. He considers it more certain, prompt, and efficacious than the bark; while it has the advantage of being admissible in the state of pyrexia, and of not disagreeing with the most irritable stomach. It has also been used by Dr. Kirchoff, of Ghent, in epilepsy with good success. Dr. Bridges, of this city, exhibited it in a case of severe and protracted facial neuralgia, with considerable relief, after the usual remedies in this complaint had been tried with little or no benefit. It is sometimes employed as an application to ill-conditioned ulcers, mixed with some simple ointment, in the proportion of a drachm to the ounce. The dose of pure Prussian blue for an adult is from three to five grains, repeated several times a day, and gradually increased until some obvious effect is produced.

Off. Prep. Hydrargyri Cyanuretum. B.

FERRI IODIDUM. *U. S., Ed., Dub. Iodide of Iron.*

"Take of Iodine *two ounces;* Iron Filings *an ounce;* Distilled Water *a pint and a half.* Mix the Iodine with a pint of the Distilled Water, in a porcelain or glass vessel, and gradually add the Iron Filings, stirring constantly. Heat the mixture gently until the liquid acquires a light-greenish colour; then filter, and, after the liquid has passed, pour upon the filter the remainder of the Distilled Water boiling hot. When this has passed, evaporate the filtered liquor at a temperature not exceeding 212°, in an iron vessel, to dryness. Keep the dry Iodide in a closely stopped bottle." *U. S.*

"Take *any convenient quantity* of Iodine, Iron Wire, and Distilled Water, in the proportions for making Solution [Syrup] of Iodide of Iron. Proceed as directed for that process; but before filtering the solution, concentrate it to one-sixth of its volume, without removing the excess of Iron Wire. Put the filtered liquor quickly in an evaporating basin, along with twelve times its weight of quicklime around the basin, in some convenient apparatus, in which it may be shut up accurately in a small space, not communicating with the general atmosphere. Heat the whole apparatus in a hot air-press, or otherwise, until the water be entirely evaporated; and preserve the dry iodide in small well closed vessels." *Ed.*

"Take of Pure Iodine *one ounce* [avoirdupois]; Filings, or thin Turnings of wrought Iron, separated from impurities by a magnet, *half an ounce* [avoird.]; Distilled Water *five ounces* [avoird.]. Introduce the Iodine, Iron, and four ounces of the Water into a Florence flask, and, having heated the mixture gently for ten minutes, boil until the solution loses its red colour. Pass the liquid now through paper into a second flask, washing the filter with the remaining ounce of Water, and, by means of a regulated heat, boil down the liquor until a drop of it taken out on the end of an iron wire solidifies on cooling. When the flask has assumed the temperature of the air, let the iodide of iron be extracted from it (by breaking the flask if necessary), and, after it has been submitted to powerful pressure, enveloped in blotting paper, let it be enclosed in a well stopped bottle." *Dub.*

In these processes iron is made to unite with iodine by the intervention of water, and the combination takes place readily and quickly. The liquid at first is red or orange-coloured, from the circumstance that all the iodine has not united with the iron; but after the application of heat it becomes fully saturated and limpid, and assumes a greenish colour. It is now a solution of iodide of iron, and yields the solid salt by evaporation. The proportion of the iron taken is half the weight of the iodine. Fine iron wire, recently cleaned, is directed by the Edinburgh College on account of its purity; but iron filings dissolve more readily, and, if carefully selected, will be sufficiently pure. It is exceedingly difficult to obtain this salt in the solid state perfectly pure, so great is the proneness of its solution to absorb oxygen, whereby the iodide becomes, in part, converted into sesquioxide. This change is prevented to a certain extent in the process of the U. S. Pharmacopœia, by evaporating to dryness in an *iron* vessel; and in the process of the Edinburgh College, by concentrating the solution, before filtering, in contact with the excess of iron wire, and afterwards evaporating it in a hot air-press, subjected to the drying influence of quicklime.

The process of the Edinburgh College for iodide of iron is that of the Messrs. T. & H. Smith, of Edinburgh. These chemists have since recommended the following improved process, which more effectually excludes atmospheric air. Boil, in a Florence flask, six drachms of pure iron filings with two ounces and a quarter of iodine, in four and a half ounces of distilled water, until the liquid loses its dark colour. Then filter the liquid rapidly into another flask, and evaporate it at a boiling heat, until its green shade passes into black. After this period, the heat is kept up as long as the evaporation of moisture continues, which may be ascertained by its condensation on a cold piece of glass, placed,

from time to time, over the mouth of the flask. When this ceases, the flask contains pure, anhydrous, spongy iodide of iron, which, when cold, is to be removed by breaking the flask, bruised coarsely in a warm dry mortar, and enclosed immediately in small well-corked bottles. If it is wished to obtain the iodide as a crystallized hydrate, the heat is to be withdrawn as soon as the liquid is sufficiently concentrated to congeal, in a dry and hard crust, on the end of an iron wire, dipped into it.

Properties. Iodide of iron is a crystalline substance, exceedingly deliquescent, of a greenish-black colour, and styptic, chalybeate taste. "When carefully prepared by the Edinburgh formula, it has a dark grayish-black metallic appearance, and irregularly foliated texture, not unlike iodine itself." (*Christison's Dispensatory.*) Its solution, by evaporation with as little contact of air as possible, affords transparent, green, tabular crystals. When heated moderately it fuses, and, on cooling, becomes an opaque crystalline mass, having an iron-gray colour and metallic lustre. At a higher temperature it emits violet-coloured vapours, and the iron is left in the state of sesquioxide. It is very soluble both in water and alcohol. When recently prepared it is wholly soluble in water, forming a pale-green solution; but if made for some time, it almost unavoidably contains some sesquioxide of iron from a partial decomposition, and will not be entirely soluble. M. Lecoq, of Saint-Quentin, has proposed to preserve it in a wide-mouthed, ground-stoppered bottle, covered with a layer of reduced iron, which cannot decompose it, and which at the same time protects it from the action of the air. When the iodide is wanted, the iron is removed with a bone spatula, or a little brush. (*Journ. de Pharm.*, Feb. 1853, p. 135.) The aqueous solution is very liable to spontaneous decomposition, becoming at last orange-red from the generation of free iodine, and depositing sesquioxide of iron. According to Mr. Richard Phillips, jun., the first step in this change is the formation of protoxide of iron and hydriodic acid, from the decomposition of water. As the protoxide immediately begins to be converted into sesquioxide by absorbing oxygen from the air, and in this state is precipitated, the hydriodic acid is set free; and hence is accounted for the acidity of the solution from the first moment the sesquioxide is deposited. Afterwards, the hydriodic acid is decomposed by the action of air, and iodine liberated. When the solution is prevented from generating free iodine, by placing in it a coil of iron wire, according to the plan of Mr. Squire, the iron acts by combining with the iodine of nascent hydriodic acid, and not with nascent iodine. (*Pharm. Journ. and Trans.*, iv. 19.) The plan of Mr. Squire does not prevent the deposition of sesquioxide, and has, therefore, been superseded by the use of saccharine matter, which affords a better protection to the solution. (See *Liquor Ferri Iodidi.*) Iodide of iron is incompatible with alkalies and their carbonates, with lime-water, and with all other substances by which sulphate of iron is decomposed. When crystallized it consists of one eq. of iodine 126·3, one of iron 28, and five of water 45=199·3.

Medical Properties and Uses. Iodide of iron was first employed in medicine by Dr. Pierquin in 1824. It was first used in the United States in 1832 by Professor Samuel Jackson, of this city, at whose request it was prepared in solution by Mr. E. Durand. The late Dr. A. T. Thomson, of London, presented it to the notice of the profession in England, as a remedy, in 1834. Its powers are those of a tonic, alterative, diuretic, and emmenagogue. As a therapeutic agent, it acts more like the preparations of iron than like those of iodine. It sometimes sharpens the appetite and promotes digestion, and occasionally acts as a laxative and diuretic. When it does not operate on the bowels, it generally augments the urine. Its use blackens the stools and lessens their fetor. It is chiefly employed in scrofulous complaints, swellings of the cervical glands, visceral obstructions attended with deficient action, chlorosis, atonic amenorrhœa,

and leucorrhœa. In the two diseases last mentioned, Dr. Pierquin employed it with success. In obstinate syphilitic ulcers, M. Baumes, of Lyons, used it with satisfactory results. He gave it in the form of pill, conjoined with extract of opium, and sometimes increased the dose to 20 grains in the course of twenty-four hours. In secondary syphilis, occurring in debilitated and scrofulous subjects, Ricord has found it a valuable remedy. The dose is a grain, gradually increased to eight or more. For forming enemata, injections for the vagina, and lotions for ulcers, one or two drachms of the salt may be dissolved in a pint of water. It should never be given in the form of pill, unless protected by saccharine matter, on account of its deliquescent property, and its proneness to decomposition; and even when thus protected, the pills become soft and lose their shape. Messrs. T. and H. Smith, of Edinburgh, have given a formula for pills of this kind, made from the anhydrous iodide of iron with refined sugar and honey. A similar pill had been previously devised by Dupasquier, and improved by Mr. H. W. Worthington, of this city, in which the protecting substances are honey and tragacanth. M. Blancard has proposed a pill of iodide of iron, made directly from its elements, protected by honey, brought to a pilular consistence with powder of marshmallow, rolled in the powder of reduced iron, and varnished with a thin coating of resin, by dipping it once or twice in an ethereal solution of the balsam of Tolu. Dr. D. F. Wright, of Memphis, Tenn., has given a formula for a similar pill, made extemporaneously from reduced iron, and protected by honey and an excess of iron. (See *Am. Journ. of Pharm.*, Jan. 1854, p. 6.) Prof. Procter is in the habit of introducing a small proportion of reduced iron into the mass, when iodide of iron is extemporaneously prescribed in pill. In view of the serious objections which apply to the solid iodide of iron, it might well be dispensed with, and the syrup or saccharine solution substituted. The London College has omitted the solid iodide from its Pharmacopœia of 1851. Solutions for external use may be formed by reducing the U. S. saccharine solution (*Liquor Ferri Iodidi*) with water to any desired extent, at the moment of using them; and, in cases in which it might be desirable to give the salt in the solid state, the officinal *syrup* could be reduced to a saccharine mass proper for making pills by evaporation to dryness. (See *Pilulæ Ferri Iodidi.*) B.

LIQUOR FERRI IODIDI. *U. S.* Syrupus Ferri Iodidi. *Lond., Dub.* Ferri Iodidi Syrupus. *Ed.* *Solution of Iodide of Iron. Syrup of Iodide of Iron.*

"Take of Iodine *two ounces;* Iron Filings *an ounce;* Sugar, in powder, *twelve ounces;* Distilled Water *a sufficient quantity.* Mix the Iodine with five fluidounces of Distilled Water, in a porcelain or glass vessel, and gradually add the Iron Filings, stirring constantly. Heat the mixture gently until all the Iodine is dissolved, or until the liquid acquires a light greenish colour. Then filter the solution into a glass bottle, containing the Sugar, and, after it has passed, pour Distilled Water gradually upon the filter until the filtered liquor, including the Sugar, measures twenty fluidounces. Lastly, shake the bottle until the Sugar is dissolved, and keep it closely stopped." *U. S.*

"Take of Iodine *an ounce;* Iron Wire *three drachms;* Distilled Water *twelve fluidounces* [Imp. meas.], or *a sufficient quantity;* Sugar *ten ounces.* Mix the Iodine and Iron with eight fluidounces of the Water, and heat until the solution acquires a greenish colour; then filter. Evaporate the solution to about four fluidounces, and throw in the Sugar. Then, when the syrup has grown cold, add sufficient Water to make it measure fifteen fluidounces [Imp. meas.], and keep it in a black glass bottle, well stopped." *Lond.*

"Take of Iodine (dry) *two hundred grains;* fine Iron Wire, recently cleaned, *one hundred grains;* White Sugar, in powder, *four ounces and a half;* Distilled Water

six fluidounces [Imperial measure]. Boil the Iodine, Iron, and Water together in a glass matrass, at first gently, to avoid the expulsion of Iodine vapour, afterwards briskly, until about two fluidounces of liquid remain. Filter this quickly, while hot, into a matrass containing the Sugar; dissolve the Sugar with a gentle heat, and add Distilled Water, if necessary, to make up six fluidounces. Twelve minims contain one grain of Iodide of Iron." *Ed.*

"Take of Pure Iodine *five drachms* [avoirdupois]; Iron Turnings, separated by a magnet, *three drachms* [Dub. weight]; Distilled Water *two ounces* [avoird.]; Simple Syrup *six fluidounces* [Imp. meas.]. Introduce the Iodine, Iron, and Water into a glass flask, and apply a moderate heat until the solution loses its red colour. Filter the solution while hot into a bottle containing the Syrup, mix with agitation, and add distilled Water, to make up eight fluidounces [Imp. meas.]. One fluidrachm contains about five grains of Iodide of Iron." *Dub.*

These preparations furnish a solution of iodide of iron, rendered more permanent by sugar. The mode of making the iodide is precisely the same as that given under the head of *Ferri Iodidum.* The Edinburgh College directs the iodine to be dry; because, if moist, as the British iodine often is, less iodide of iron will be formed, and the syrup will be proportionably weaker. (See *Iodinium Purum.*) In all the processes an excess of iron is taken, the excess being greatest in the Dublin formula, and least in the London. A moderate excess of iron is useful in preventing the solution of iodide of iron from undergoing any change from the absorption of oxygen during filtration, before it comes in contact with the sugar. Assuming that the iodine without loss is all converted into iodide of iron, it is easy to calculate the strength of the several officinal solutions. Thus it will be found that the U. S. solution contains 7½ grains, and those of the British Colleges about 5 grains of the dry iodide to the fluidrachm. In the British preparations sufficient sugar is used to constitute a syrup; in the U. S. preparation, much less sugar is directed. According to Mr. W. Tozier, of Kingstown, Ireland, the proportion of sugar in the British formulæ is not sufficient fully to protect the iodide from change; and, if this statement be accurate, the saccharine strength of the U. S. preparation must be deemed altogether inadequate. Prof. Procter is of opinion that the iodide of iron in the U. S. formula would be better protected by more sugar. A coil of iron wire, or a strip of bright iron, immersed in the solution, assists in preserving it from change.

The plan of protecting the solution of iodide of iron from change by saccharine matter originated with M. Frederking, of Riga, who published a formula for the purpose in *Buckner's Repertorium* in 1839. The same plan was proposed in a paper by Prof. Procter, contained in the *Amer. Journ. of Pharmacy* for April 1840. In the *Journal de Pharmacie* for March 1841, Dr. Dupasquier, of Lyons, claims to have made a pure iodide of iron, protected by syrup of gum, as early as 1838. In the *Pharm. Journ. and Trans.* for August 1841, the late Dr. A. T. Thomson gave a paper in which he confirmed the results of Frederking and Procter, and proposed a formula for a *strong syrup*, which is the basis of that adopted in the British Pharmacopœias.

Properties. The *U. S. solution of iodide of iron* is a transparent liquid, free or nearly so from sediment, and of a pale-green colour. It becomes brown on the addition of sulphuric acid, and emits violet vapours when heated. It should not contain any free iodine, which, if present, may be detected by the production of a blue colour with starch. The *syrup of the British Colleges* is a transparent liquid, either colourless or pale yellowish-green, and without sediment even when exposed to the air. When concentrated it becomes brown, and, when evaporated to dryness, it forms a mass which may be called the *saccharine iodide*, and which is not entirely soluble again, a little sesquioxide of iron being left. This saccharine iodide, being protected by the sugar it contains, is not

liable to the objections which apply to the pure solid salt, and may be made into pills. (See *page* 1005.)

Medical Properties. These have been detailed under the head of *Ferri Iodidum.* The dose of the U. S. *solution* is from 20 to 50 drops, sufficiently diluted with water; that of the *syrup* of the British Colleges, one-half larger. The dilution should be made at the moment it is taken; and, in order to guard against injury to the teeth, the mouth should be carefully washed after each dose. B.

LIQUOR FERRI NITRATIS. *U. S.* FERRI PERNITRATIS LIQUOR. *Dub. Solution of Nitrate of Iron. Solution of Pernitrate of Iron. Solution of Ternitrate of Sesquioxide of Iron.*

"Take of Iron Wire, cut in pieces, *an ounce;* Nitric Acid [sp. gr. 1·42] *three fluidounces;* Distilled Water *a sufficient quantity.* Mix the Acid with a pint of Distilled Water, add the Iron, and agitate occasionally until gas ceases to be disengaged; then filter the solution, and add to it sufficient Distilled Water to make it measure thirty fluidounces." *U. S.*

"Take of fine Iron Wire, free from rust, *one ounce* [avoirdupois]; Pure Nitric Acid [sp. gr. 1·5] *three fluidounces* [Imp. meas.]; Distilled Water *a sufficient quantity.* Into the Acid, first diluted with sixteen ounces [avoird.] of the Water, introduce the Iron Wire, and leave them in contact until gas ceases to be disengaged. Filter the solution, and to it add as much Water as will make its bulk one pint and a half [Imp. meas.]. The specific gravity of this Solution is 1·107." *Dub.*

Upon a comparison of these formulæ, it will be found that the U. S. process differs from the Dublin in substituting the troy for the avoirdupois ounce of iron, and three wine fluidounces of nitric acid, sp. gr. 1·42, for three Imperial fluidounces of the same acid, sp. gr. 1·5. These variations from the Dublin formula increase the iron taken 42½ grains, and lessen the weight of the acid; for three wine fluidounces of nitric acid, sp. gr. 1·42, weigh 27½ grains less than the three Imp. fluidounces of the acid, sp. gr. 1·5. The comparative deficiency of acid in the U. S. formula is much greater than this, when the sp. gr. of the U. S. acid compared with that of the Dublin acid, is taken into account. These differences, however, do not appear material; for, on the supposition that the preparation contains the ternitrate of sesquioxide of iron, there is not enough acid taken in either formula to dissolve all the iron. To produce this salt, four eqs. of nitric acid may be supposed to react with two eqs. of iron. One eq. of the nitric acid, with evolution of nitric oxide, will be expended in converting the iron into sesquioxide, with which the three remaining eqs. of acid will unite. $4NO_5$ and $2Fe = Fe_2O_3, 3NO_5$ and NO_2.

This solution was introduced to the notice of the profession by Mr. William Kerr, of Scotland, in 1832. As made by Mr. Kerr, it is a transparent liquid of a beautiful dark-red colour, and a very astringent but not caustic taste. Its sp. gr., as made by the Dublin formula, is 1·107. It is apt to become turbid on keeping, and to deposit a subnitrate of the sesquioxide. To obviate this liability to change, Mr. Kerr always added a small portion of muriatic acid. Prof. Procter attains the same end by adding the iron gradually, filtering immediately after all the iron has been thrown in, heating the filtrate gently in a capsule or flask, and carefully dropping in nitric acid, with stirring, avoiding an excess, until a drop of the solution, tested with ammonia, yields a red precipitate, without any tinge of black. By thus preventing a prolonged contact between the salt formed and metallic iron, but little protoxide is generated; and this is subsequently turned into sesquioxide and saturated by the careful addition of nitric acid. (See *Am. Journ. of Pharm.* Oct. 1851, p. 313.) Solution of nitrate of iron, made by Prof. Procter's modified formula, has a bright Madeira wine colour,

and keeps very well. When treated with ammonia, it yields a red precipitate of sesquioxide of iron. The late Mr. Duhamel, of Philadelphia (*Am. Journ. of Pharm.*, xvii. 92) proposed to render the solution permanent by preparing it as a syrup; but it is well known that his syrup would not keep.* *Ternitrate of sesquioxide of iron*, as described by Mr. J. M. Ordway, of Massachusetts, is in the form of oblique rhombic prisms, which are either colourless or of a delicate lavender colour. It is somewhat deliquescent, and very soluble in water, but sparingly soluble in nitric acid. It consists of three eqs. of nitric acid, one of sesquioxide of iron, and eighteen of water. (*Silliman's Journ.*, Jan. 1850.)

Medical Properties. This solution is considered to act as a tonic and astringent. Dr. R. J. Graves, of Dublin (*Am. Journ. of Med. Sci.*, xviii. 216, from the *Lond. Med. and Surg. Journ.*), praises it as a remedy in chronic diarrhœa, especially when occurring in delicate and nervous women, in which there is no thirst, redness of tongue, tenderness of the abdomen on pressure, or other indication of inflammation. Mr. Kerr attributed to it the property of diminishing the irritability of the intestinal mucous membrane. It is particularly applicable to the treatment of mucous diarrhœa, attended with pain, but not to cases in which ulcerations of the intestines exist. Dr. T. C. Adams, of Michigan (*Amer. Journ. of Med. Sci.*, xxiv. 61), also reports favourably of this remedy in chronic diarrhœa, considering it, like Mr. Kerr, to act as a sedative as well as astringent. He employed it, likewise, with good effect in menorrhagia, and both internally and by injection in leucorrhœa, when occurring in pale, exsanguine, and feeble subjects. The dose, according to Dr. Graves, is seven or eight drops, gradually increased to fifteen, sufficiently diluted, in the course of the day. Dr. Adams, however, gave it in doses of ten drops, two, three, or four times a day, and sometimes increased it to twenty-five drops. As an injection he employed it sufficiently diluted to cause only a slight heat and smarting in the vagina. B.

FERRI OXIDUM HYDRATUM. *U. S.* Ferrugo. *Ed.* Ferri Peroxydum Hydratum. *Dub.* *Hydrated Oxide of Iron. Hydrated Peroxide of Iron. Hydrated Sesquioxide of Iron.*

"Take of Sulphate of Iron *four ounces;* Sulphuric Acid *three fluidrachms and a half;* Nitric Acid *six fluidrachms*, or *a sufficient quantity;* Solution of Ammonia *a sufficient quantity;* Water *two pints.* Dissolve the Sulphate of Iron

* Prof. Procter has proposed the following formula for preparing a *syrup of the nitrate of protoxide of iron*, a preparation considerably used, in Philadelphia, as an astringent in chronic diarrhœa. Take of iron wire, in pieces (card teeth), *two ounces;* nitric acid (sp. gr. 1·42) *three fluidounces;* water *thirteen fluidounces;* sugar, in powder, *two pounds.* Put the iron in a wide-mouthed bottle, kept cool by standing in cold water, and pour upon it three fluidounces of water. Then mix the acid with ten fluidounces of water, and add the mixture in portions of half a fluidounce to the iron, agitating frequently until the acid is saturated, using litmus paper. When the saturation is complete, filter the solution into a bottle containing the sugar, and marked to contain thirty fluidounces. If the whole does not measure that bulk, pass water through the filter to make up the deficiency. When all the sugar is dissolved, strain if necessary, and introduce the syrup into suitable vials, and seal them. This syrup is thick, permanent, of a light-greenish colour, perfectly transparent, neutral, and yields a greenish precipitate with ammonia. (*Am. Journ. of Pharm.*, Oct. 1851, p. 314.) Mr. W. W. D. Livermore has given a formula for a similar syrup. (*Ibid.* p. 315.) These syrups should not contain an excess of acid; for if they do, they are apt to deposit, after keeping, white granular masses of grape sugar, as observed by Mr. W. Tozier, of Kingstown, Ireland, in consequence of the action of the acid upon the cane sugar. According to Mr. Joseph Laidley, of Richmond, Va., the so-called syrup of the nitrate of sesquioxide of iron is an unscientific preparation, containing protoxide if an excess of acid is avoided, and liable to let fall a precipitate of oxalate of iron when the acid is in excess. These objections do not apply to Prof. Procter's syrup, containing the protoxide; and hence Mr. Laidley believes that the only nitrate, proper to be formed into a syrup, is the nitrate of the protoxide, where alone the protective action of sugar is required. (*Ibid.*, March, 1853, p. 97.)—*Note to the tenth edition.*

in the Water, and, having added the Sulphuric Acid, boil the solution; then add the Nitric Acid in small portions, boiling the liquid for a minute or two after each addition, until the acid ceases to produce a dark colour. Filter the liquid, allow it to cool, and add Solution of Ammonia in excess, stirring the mixture briskly. Wash the precipitate with water until the washings cease to yield a precipitate with chloride of barium, and keep it in close bottles with water sufficient to cover it." *U.S.*

"Take of Sulphate of Iron *four ounces;* Sulphuric Acid (commercial) *three fluidrachms and a half* [Imp. meas.]; Nitric Acid (D. 1·380) *nine fluidrachms* [Imp. meas.]; Stronger Aqua Ammoniæ *three fluidounces and a half* [Imp. meas.]; Water *two pints* [Imp. meas.]. Dissolve the Sulphate in the Water, add the Sulphuric Acid, and boil the solution; add then the Nitric Acid in small portions, boiling the liquid for a minute or two after each addition, until it acquires a yellowish-brown colour, and yields a precipitate of the same colour with ammonia. Filter, allow the liquid to cool, and add in a full stream the Aqua Ammoniæ, stirring the mixture briskly. Collect the precipitate on a calico filter; wash it with water till the washings cease to precipitate with nitrate of baryta; squeeze out the water as much as possible, and dry the precipitate at a temperature not exceeding 180°. When this preparation is kept as an antidote for poisoning with arsenic, it is preferable to preserve it in the moist state, after being simply squeezed." *Ed.*

"Take of Sulphate of Iron *eight ounces* [avoirdupois]; Pure Sulphuric Acid *six fluidrachms* [Imp. meas.]; Pure Nitric Acid *half a fluidounce* [Imp. meas.]; Solution of Caustic Potash *one quart* [two pints, Imp. meas.]; Distilled Water *twelve ounces* [avoird.]. To ten ounces of the Water add the Sulphuric Acid, and in the mixture with the aid of heat dissolve the Sulphate of Iron. Mix the Nitric Acid with the remainder of the Water, and, having added the Diluted Acid to the solution of Sulphate of Iron, concentrate by boiling, until, upon the sudden disengagement of much gas, the liquid passes from a dark to a red colour. Let this be now poured into the Solution of Caustic Potash, and, when the mixture has been well stirred, place it on a calico filter, and let the precipitate be washed with distilled water until the liquid which passes through ceases to give a precipitate when dropped into a solution of chloride of barium. Lastly, enclose the precipitate, while in the pasty state, in a porcelain pot whose lid is made air-tight by a luting of lard, so as to prevent the loss of water by evaporation." *Dub.*

This preparation was introduced into the officinal catalogues on account of its importance as an antidote to the poison of arsenious acid. The first step of the processes is to convert the sulphate of protoxide of iron into the tersulphate of the sesquioxide, precisely as is done in the U. S. formula for pure Prussian blue. The sesquioxide is then thrown down in the hydrated state by the addition of ammonia in excess in the U. S. and Edinburgh formulæ, and by potassa in the Dublin. The precipitate is then washed with water to remove adhering sulphate of ammonia or of potassa, until the washings cease to precipitate with a barytic salt. In the U. S. Pharmacopœia the precipitate is directed to be kept in close bottles with sufficient water to cover it, in which state it is most convenient for use as an antidote. The Edinburgh College directs it to be kept in two states; dried at a temperature not exceeding 180° for use as a medicine, and in the moist state as an antidote.

Besides having this antidote ready formed in the pulpy state, it is the duty of the apothecary to be always prepared to make it, by keeping the necessary solutions for its precipitation. These are the tersulphate of sesquioxide of iron in solution, made as directed in the above formulæ, and solution of ammonia. In relation to this subject the reader is referred to a paper, by Prof. Procter, in the *Am. Journ. of Pharm.* for March, 1853, p. 104.

Properties. Hydrated oxide of iron, as directed to be kept by the U. S. formula, is a soft, moist, reddish-brown magma. If dried at a heat not exceeding 180°, and afterwards pulverized, it forms a reddish-brown powder, not attracted by the magnet, being the sesquioxide in the state of hydrate, containing about 18 per cent. of water. In this state it is wholly and readily soluble in muriatic acid without effervescence. If exposed to a red heat, it loses the combined water, and becomes the anhydrous sesquioxide, less easily soluble in acids, improper for medicinal use, and altogether without effect as an antidote. Hydrated oxide of iron consists of one eq. of sesquioxide 80, and two of water 18=98, and is represented by the formula Fe_2O_3+2HO.

Medical Properties and Uses. The hydrated oxide, being readily soluble in acids, would no doubt form, in the dry state, a good ferruginous preparation for medicinal employment. Its antidotal powers in cases of poisoning by arsenic, the manner in which it acts, the circumstances which impair its efficiency, and the mode of using it, are fully explained under the head of arsenious acid, *page* 27. Its power of rendering arsenious acid insoluble is readily shown by agitating a solution of the acid with a considerable excess of the moist oxide, filtering, and then testing the filtered solution for the acid; when not a trace of the metal can be detected, even by sulphuretted hydrogen. The hydrated oxide, as obtained by the U. S. and Edinburgh formulæ, contains a little ammonia, which is thought by some to assist its antidotal powers. At least it has been ascertained that the sesquioxide, precipitated by potassa, as directed by the Dublin College, is a less efficient antidote to arsenic than when ammonia is used as the precipitant, and must be employed in quantities three or four times as large to produce the same effect. The dry hydrate, rubbed up with water, is in the same proportion weaker than the pulpy hydrate. It has already been mentioned, under arsenious acid, that the officinal subcarbonate of iron (formerly called precipitated carbonate) possesses antidotal powers to arsenic, though in an inferior degree; but this statement will not apply to it, after having been exposed to a red heat, to which it is improperly subjected by some manufacturing chemists. By ignition it becomes anhydrous, and is rendered altogether inefficient as an antidote.

FERRI OXIDUM NIGRUM. *Ed.* *Black Oxide of Iron.*

"Take of Sulphate of Iron *six ounces;* Sulphuric Acid (commercial) *two fluidrachms and two fluid scruples;* Pure Nitric Acid *four fluidrachms and a half;* Stronger Aqua Ammoniæ *four fluidounces and a half;* boiling Water *three pints* [Imperial measure]. Dissolve half the Sulphate in half the boiling Water, and add the Sulphuric Acid; boil; add the Nitric Acid by degrees, boiling the liquid after each addition briskly for a few minutes. Dissolve the rest of the Sulphate in the rest of the boiling Water; mix thoroughly the two solutions; and immediately add the Ammonia in a full stream, stirring the mixture at the same time briskly. Collect the black powder on a calico filter; wash it with water till the water is scarcely precipitated by a solution of nitrate of baryta, and dry it at a temperature not exceeding 180°." *Ed.*

The black oxide of iron of the Edinburgh College is here made by the process of Wöhler, which consists in precipitating by ammonia a solution of the mixed sulphates of protoxide and sesquioxide of iron. Half the sulphate of iron taken in the formula, after having been dissolved in water, is acidulated with sulphuric acid, and converted into the tersulphate of the sesquioxide by means of nitric acid. The object of the addition of the sulphuric acid is explained under the head of Prussian blue. (See *Ferri Ferrocyanuretum.*) The other half of the sulphate is dissolved in water, and the two solutions, being thoroughly mixed, form a compound solution of sulphate of the protoxide and tersulphate of the sesquioxide of iron. From this the ammonia throws down, at the same moment, both the protoxide and sesquioxide, which unite chemically to form the black

oxide of the Edinburgh College. According to Mr. Phillips, the black oxide may be readily obtained by mixing boiling solutions of equivalents of carbonate of soda and sulphate of protoxide of iron, and adding, by small portions at a time, somewhat less than an eq. of chlorate of potassa. If a whole eq. of the chlorate be added, and at once, the hydrated sesquioxide would be obtained.

Properties. The black oxide of iron of the Edinburgh College is a dark grayish-black powder, unchangeable in the air, and strongly magnetic. When dried in mass and then broken, it presents a shining fracture. It is wholly soluble in muriatic acid without effervescence, and may be thrown down again as a black precipitate by ammonia. When heated in close vessels it suffers no change except the loss of water; but in open vessels it absorbs oxygen, and is converted entirely into sesquioxide. It consists of two eqs. of protoxide of iron, one of sesquioxide, and two of water, and its formula is $2FeO,Fe_2O_3+2HO$. It is perceived by the above symbols, that the two oxides are united in it in such proportions as to contain, each, the same quantity of iron; and this composition corresponds with what it should be, according to the direction given in the formula to divide the sulphate of iron into two equal portions.

Medical Properties. The Ed. black oxide is a valuable chalybeate, having the merit of uniform composition and permanency under the influence of air and moisture. The dose is from five to twenty grains, two or three times a day. B.

FERRI OXYDUM MAGNETICUM. *Dub. Magnetic Oxide of Iron. Martial Ethiops.*

"Take of Sulphate of Iron *twelve ounces* [avoirdupois]; Solution of Caustic Potash *fifty-four ounces* [avoird.]; Distilled Water *a sufficient quantity.* Convert, as is directed in the formula for *Ferri Peroxydum Hydratum*, eight ounces of the Sulphate of Iron into a persulphate. To the solution thus obtained add the four remaining ounces of the Sulphate of Iron, first dissolved in half a pint [Imp. meas.] of Distilled Water. Mix well the resulting liquid with the Solution of Caustic Potash, and, having boiled for five minutes in an iron vessel, collect the precipitate on a calico filter, and wash it with boiling distilled water, until the liquid which passes through ceases to give a precipitate when dropped into a solution of chloride of barium. Lastly, let the precipitate be dried by a steam or water heat, and, having been first reduced to a fine powder, let it be enclosed in a well stopped bottle." *Dub.*

In this formula, two-thirds of the sulphate of protoxide of iron taken is converted into tersulphate of the sesquioxide. The remaining third of the sulphate is then dissolved in water, and mixed with the solution of the tersulphate. A compound solution is thus obtained, containing two-thirds of the iron in the state of sesquioxide, and one-third in that of protoxide. When this solution is treated with potassa, a mixed precipitate of one eq. of sesquioxide and one of protoxide is thrown down. Now such a compound oxide corresponds in composition with the native magnetic black oxide. The precipitate is washed to remove sulphate of potassa, and the washings are known to be completed, when the chloride of barium ceases to give a precipitate with them.

Properties, &c. The artificial magnetic oxide of iron of the Dublin College is a dark grayish-black powder, having the same general appearance as the Edinburgh black oxide. It is formed almost always to some extent in the process for making reduced iron, in consequence of the partial deoxidation of part of the sesquioxide by the hydrogen. (See *Ferri Pulvis*, p. 995.) It differs from the Edinburgh black oxide in composition, containing one eq. of protoxide to one of sesquioxide; whereas the Edinburgh oxide contains two eqs. of protoxide to one of sesquioxide. The Dublin preparation has the same medical properties as the corresponding one of the Edinburgh College. The dose is from five to twenty grains given several times a day. B.

FERRI PEROXYDUM. *Dub.* *Peroxide of Iron.* *Sesquioxide of Iron.*

"Take of Hydrated Peroxide of Iron *any convenient quantity.* Place it in an oven on a few folds of filtering paper, and, when it has become dry to the touch, transfer it to a covered crucible, and expose it for a few minutes to an obscure red heat." *Dub.*

This is the former Dublin red oxide of iron under a new name, and formed by a better process. The dried hydrated oxide loses, by ignition, its combined water, and is converted into the pure sesquioxide.

Properties, &c. This oxide is a reddish-brown, tasteless, insoluble powder, identical with the colcothar of commerce. It should not be deliquescent, and should dissolve in muriatic acid without effervescence. If it contain copper, its muriatic solution will deposit this metal on a bright piece of iron. It consists of two eqs. of iron 56, and three of oxygen 24=80. It is, therefore, a sesquioxide. As it is anhydrous, it has no effect as an antidote to arsenious acid. This oxide is not used as a medicine, and is employed by the Dublin College only in making iron plaster and powder of iron, for which purposes other forms of oxidized iron would answer as well. The former Dublin *Rubigo Ferri* or *rust of iron*, formed by exposing moistened iron wire to the air till converted into rust, is essentially the sesquioxide, containing a little carbonate of the protoxide.

FERRI PHOSPHAS. *U. S.* *Phosphate of Iron.*

"Take of Sulphate of Iron *five ounces;* Phosphate of Soda *six ounces;* Water *a gallon.* Dissolve the Sulphate of Iron and Phosphate of Soda, severally, in four pints of the Water; then mix the solutions, and set the mixture by that the powder may subside; lastly, having poured off the supernatant liquor, wash the Phosphate of Iron with hot water, and dry it with a gentle heat." *U. S.*

This preparation is the result of a double decomposition between the saline materials employed. As the medicinal phosphate of soda is the tribasic phosphate, having the composition, $2NaO,HO,PO_5$, it follows that it requires two eqs. of sulphate of protoxide of iron for its decomposition, as shown by the following equation. $2(FeO,SO_3)$ and $2NaO,HO,PO_5=2FeO,HO,PO_5$ and $2(NaO,SO_3)$. The resulting salts, therefore, are one eq. of tribasic phosphate of iron, the salt under notice, and two eqs. of sulphate of soda, which are washed away. If the ferruginous sulphate be a perfect sulphate of the protoxide, the precipitate as first thrown down will be white; but it quickly absorbs oxygen and becomes bluish-white. It is in the form of a powder of a bright slate colour, insoluble in water, but soluble in acids. When perfect, it consists of one eq. of phosphoric acid, two of protoxide of iron, and one of basic water; but generally it contains some phosphate of the sesquioxide ($2Fe_2O_3,3HO,3PO_5$).

Phosphate of iron, dissolved to saturation in a boiling solution of metaphosphoric acid (HO,PO_5), under the name of *superphosphate of iron*, was brought forward as a new remedy, in Jan. 1851, by Dr. Routh, of London. Mr. Thomas Greenish, of the same city (*Pharm. Journ. and Trans.*, May, 1851), states that the solution of the salt, on cooling, hardens into a mass of a pilular consistence, soluble in water in all proportions, and free from any disagreeable or inky taste. From this superphosphate Mr. Greenish has prepared a syrup, containing five grains of the salt to the fluidrachm.

If two eqs. of tersulphate of sesquioxide of iron be decomposed by three eqs. of pyrophosphate of soda, one eq. of pyrophosphate of sesquioxide of iron is precipitated, and six eqs. of sulphate of soda remain in solution. $2(Fe_2O_3,3SO_3)$ and $3(2NaO,PO_5)=2Fe_2O_3,3PO_5$ and $6(NaO,SO_3)$. This ferruginous pyrophosphate is soluble in an excess of pyrophosphate of soda; and this and similar solutions of pyrophosphates were proposed as medicines by Persoz in 1848. Mr.

Alex. Ure, of London (*Pharm. Journ. and Trans.* for Dec. 1851), tried the solution of the ferruginous pyrophosphate, calling it *soda-pyrophosphate of iron*, in scrofula, and found it a mild and efficient chalybeate. In this instance the sulphate of soda, resulting from the double decomposition, was not separated. The same solution has been prepared as a syrup by M. Soubeiran, under the name of *syrup of pyrophosphate of iron.* (*Journ. de Pharm.*, 3*e sér.* xxiii. 62.)*

Medical Properties. Phosphate of iron possesses the general properties of the ferruginous preparations, and has been given with advantage in amenorrhœa and some forms of dyspepsia. It was introduced into the U. S. Pharmacopœia at the suggestion of the late Dr. Hewson, of this city, who found it, after an extensive experience, to be a valuable chalybeate. The dose is from five to ten grains. B.

FERRI SUBCARBONAS. *U. S.* Ferri Sesquioxidum. *Lond.* Ferri Oxidum Rubrum. *Ed.* Ferri Carbonas. *Dub. Subcarbonate of Iron. Sesquioxide of Iron. Red Oxide of Iron. Precipitated Carbonate of Iron.*

"Take of Sulphate of Iron *eight ounces;* Carbonate of Soda *nine ounces;* boiling Water *a gallon.* Dissolve the Sulphate of Iron and Carbonate of Soda, severally, in four pints of the Water; then mix the solutions, and having stirred the mixture, set it by that the powder may subside; lastly, having poured off the supernatant liquor, wash the Subcarbonate of Iron with hot water, wrap it in bibulous paper, and dry it with a gentle heat." *U. S.*

"Take of Sulphate of Iron *four pounds;* Carbonate of Soda *four pounds and two ounces;* boiling Water *six gallons* [Imp. meas.]. Dissolve the Sulphate and Carbonate, separately, in three gallons of the Water. Mix the solutions together while yet hot, and set them by that the precipitate may subside. Having poured off the supernatant liquor, wash the precipitate repeatedly with water, and dry it." *Lond.*

"Take of Sulphate of Iron *four ounces;* Carbonate of Soda *five ounces;* boiling Water *half a pint* [Imp. meas.]; cold Water *three pints and a half* [Imp. meas.]. Dissolve the Sulphate in the boiling Water, add the cold Water, and then the Carbonate of Soda, previously dissolved in about thrice its weight of water. Collect the precipitate on a calico filter; wash it with water till the water is but little affected with solution of nitrate of baryta, and dry it in the hot air-press, or over the vapour-bath." *Ed.*

"Take of Sulphate of Iron *eight ounces* [avoird.]; Crystallized Carbonate of Soda of Commerce *ten ounces* [avoird.]; Distilled Water *two gallons* [Imp. meas.]. Dissolve each salt in one-half of the Water, and, both solutions being raised to the boiling temperature, mix them, and set the whole to rest in a covered vessel for six hours. The supernatant solution having been drawn off with a syphon, the precipitate is to be drained on a calico filter, and then subjected to strong expression. Finally, let it be dried at a temperature not exceeding 212°, pulverized, and preserved in a well stopped bottle." *Dub.*

When the solutions of carbonate of soda and sulphate of iron are mixed together, a hydrated carbonate of protoxide of iron, of a pale-bluish colour, is

* M. Soubeiran's formula is as follows: Add 55 *grains* of tersulphate of sesquioxide of iron, dissolved by a gentle heat, in 2 *fluidounces* of water, to 462 grains of crystallized pyrophosphate of soda, dissolved in 7½ *fluidounces* of water and 3½ of mint water, and mix. So soon as the precipitate formed redissolves, filter the solution, and add to the filtrate 19 *ounces troy* of white sugar, which must be allowed to dissolve without heat. The dose of this syrup, which is easy to take, is a tablespoonful, containing about a third of a grain of iron in the state of a double pyrophosphate. For a formula for a compound syrup of phosphate of iron by Mr. Wiegand, and for some remarks on the pharmacy of the phosphates by Prof. Procter, see the *Am. Journ. of Pharm.* for March, 1854, pp. 111 and 112.—*Note to the tenth edition.*

thrown down, and sulphate of soda remains in solution. The equivalent quantities of the *crystallized* salts for mutual decomposition are 139 of the sulphate and 143·3 of the carbonate. Taking the quantity of sulphate of iron at 8 parts, the London Pharmacopœia orders of carbonate of soda 8½ parts, the U. S. Pharmacopœia 9 parts, and the Edinburgh and Dublin 10 parts. The proportion of the London College coincides most nearly with the equivalents. The precipitate, during the washing and drying, absorbs oxygen, and loses nearly all its carbonic acid, whereby it is converted almost entirely into sesquioxide of iron. This being the chemical nature of the preparation, the London College has given it the name of *Ferri Sesquioxidum;* but, as this is applicable to the red oxide obtained by calcining the sulphate, or igniting the hydrated sesquioxide, the U. S. name of *Ferri Subcarbonas*, adopted in allusion to the small quantity of carbonic acid present in it, is more distinctive. Carbonate of potassa will answer to decompose the ferruginous sulphate; but carbonate of soda is preferred, because it produces in the double decomposition sulphate of soda, which, from its greater solubility, is more readily washed away than sulphate of potassa.

Properties. Subcarbonate of iron is a reddish-brown powder, of a disagreeable, slightly styptic taste; insoluble in water, and not readily dissolved by any acid except the muriatic, with which it effervesces slightly. After precipitation from its muriatic solution by ammonia or potassa, either of which throws down the sesquioxide of iron, the supernatant liquor should give no indications of containing any metal in solution by the test of sulphuretted hydrogen or ferrocyanuret of potassium. It is incompatible with acids and acidulous salts. In composition it is a hydrated sesquioxide of iron, containing a little protoxide and carbonic acid.

Medical Properties and Uses. Subcarbonate of iron is tonic, alterative, and emmenagogue, and is employed for all the purposes to which the preparations of iron are generally applicable. It was recommended by Mr. Carmichael in cancer, and is said sometimes to prove useful. Mr. Hutchinson brought it into notice as a remedy for neuralgia; and an extensive experience with it in that disease has established its value. It is also useful in chorea, in chlorosis, and, generally, in those diseases in which the blood is deficient in colouring matter. It has been used by Dr. Woollam, Dr. Shearman, Dr. Elliotson, and others in traumatic tetanus, with success in twelve cases and failure in three. In the second stage of hooping-cough, Dr. Steymann represents it to be a prompt and efficacious remedy. When prescribed as a tonic, the usual dose is from five to thirty grains three times a day, given in pill or powder, and frequently combined with aromatics and vegetable tonics. In neuralgia, chorea, and tetanus, it is administered in doses of from one to two teaspoonfuls. No nicety need be observed in the dose; its only obvious effect in very large doses being a slight nausea, and a sense of weight at the stomach. It blackens the stools.

The subcarbonate of iron acts as an antidote to the poison of arsenious acid, provided it has not been exposed to a red heat; and, though not so powerful as the hydrated oxide in the form of magma, should always be used till the latter can be procured. (See *page* 28.)

FERRI SULPHAS. *U. S., Lond., Ed., Dub. Sulphate of Iron. Green Vitriol.*

"Take of Iron Wire, cut in pieces, *twelve ounces;* Sulphuric Acid *eighteen ounces;* Water *a gallon.* Mix the Sulphuric Acid and Water, and add the Iron; then heat the mixture until effervescence ceases. Pour off the solution, and, having added half a drachm of Sulphuric Acid, filter through paper, allowing the lower end of the funnel to touch the bottom of the receiving ves-

sel. Evaporate the filtered liquor in a matrass until sufficiently concentrated; then set it aside in a covered vessel to crystallize. Drain the crystals in a funnel, dry them on bibulous paper, and keep them in closely stopped bottles." *U. S.*

"Take of Commercial Sulphate of Iron *four pounds;* Sulphuric Acid *a fluidounce* [Imp. meas.]; Iron Wire *an ounce;* Distilled Water *four pints* [Imp. meas.]. Mix the Acid with the Water, and add to them the Sulphate and Iron; then apply heat, stirring occasionally, until the Sulphate is dissolved. Filter the solution while yet hot, and set aside to crystallize. Pour off the liquor, and evaporate it that crystals may again form. Dry all the crystals." *Lond.*

"If the Sulphate of Iron of Commerce be not in transparent green crystals, without efflorescence, dissolve it in its own weight of boiling water, acidulated with a little Sulphuric Acid; filter, and set the solution aside to crystallize. Preserve the crystals in well closed bottles." *Ed.*

"Take of Iron Wire, or turnings of wrought Iron, *four ounces* [avoird.]; Oil of Vitriol of Commerce *four fluidounces* [Imp. meas.]; Distilled Water *one pint and a half* [Imp. meas.]. Pour the Water on the Iron placed in a porcelain capsule, add the Oil of Vitriol, and, when the disengagement of gas has nearly ceased, boil for ten minutes. Filter now through paper, and, having separated the crystals which, after the lapse of twenty-four hours, will have been deposited from the solution, let them be dried upon blotting-paper placed upon a porous brick, and then preserved in a well stopped bottle." *Dub.*

The object of the U. S. and Dublin processes is to make a pure sulphate of the protoxide of iron by direct combination. Sulphuric acid, in a concentrated state, acts but imperfectly on iron; but when diluted, a vigorous action takes place, the oxygen of the water converts the metal into protoxide, with which the sulphuric acid unites, and hydrogen is evolved. The equivalent quantities for mutual reaction are 28 of iron to 49 of acid. This proportion is one part of iron to one and three-quarters of acid. The *U. S.* proportion is one part of iron to one and a half of acid, and gives a quantity of iron one-sixth more than the acid can dissolve. The *Dublin* College uses an excess of acid, the weight of acid taken being 7·38 avoirdupois ounces, instead of 7. An excess of iron, however, is desirable; as it tends to secure the production of a perfect sulphate of the protoxide. The remaining steps of the U. S. process are peculiar, and are intended to secure the formation of a salt entirely free from sesquioxide, by the method of Bonsdorff. This chemist found that, when a perfect sulphate of protoxide of iron was formed in solution by heating dilute sulphuric acid with an excess of iron, it might be crystallized free from sesquioxide, provided a little excess of sulphuric acid were added to the liquid before filtration, in order to hold in solution any sesquioxide that may have been formed; at the same time avoiding, as much as possible, the contact of the air. Hence the directions in the U. S. formula to acidulate with sulphuric acid, to cause the funnel to touch the bottom of the receiving vessel, which avoids the dropping of the liquid through the air, and to cover the vessel containing the concentrated liquid, when it is set aside to crystallize. The *London* formula proceeds upon the plan of purifying the commercial sulphate. The salt is dissolved in water, acidulated with a quantity of sulphuric acid, equal to about $\frac{1}{2}\frac{1}{7}$th of the weight of the salt. A portion of iron is placed in the solution to precipitate copper, should this happen to be an impurity, and to convert any sesquioxide of iron present into protoxide. The latter effect is produced as a consequence of the decomposition of water, the nascent hydrogen of which reduces the sesquioxide to protoxide. Heat is then applied, and the solution is filtered hot and set aside to crystallize. The *Edinburgh* College purifies the commercial sulphate in a similar manner, but gives less precise directions, and omits the use of metallic iron.

Properties. Sulphate of iron is in the form of transparent crystals, efflorescent in the air, of a pale bluish-green colour, and having the shape of oblique
